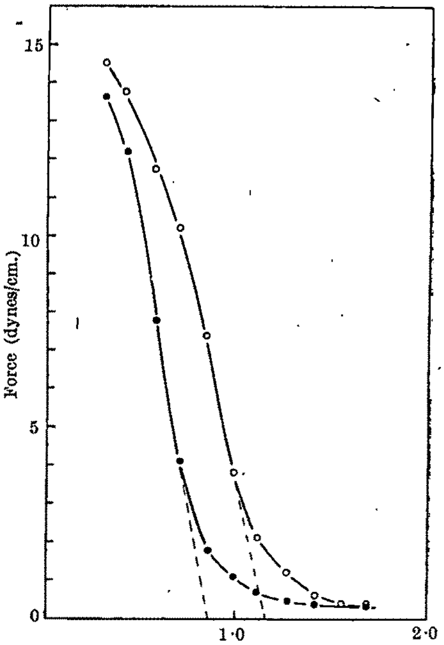
The influence of adenosine triphosphate and related substances on the force-area relationships of monolayers of actin-free myosin and the complex actomyosin has been studied. The proteins in question were isolated by Szent-Györgyi's method[5]. Actin was obtained in aqueous solution, actomyosin and myosin proper in salt solutions (0·6 *M* potassium chloride). The solutions were diluted to approximately 0·2 per cent (referred to dry-weight determinations) and roughly filtered before spreading.

Actin spreads on water or salt solutions, whereas actomyosin and actin-free myosin spread effectively only on solutions of considerable ionic strength. The most favourable conditions were provided by using a veronal buffer of *p*H 5·3, made 0·6 *M* with respect to potassium chloride, in all experiments.

Each film was allowed to spread for four minutes at zero pressure before readings were taken. Experimental data for a sample of actomyosin are recorded in the accompanying graph. When adenosine triphosphate is added to the substrate to a final concentration of 0·05 mgm./ml. (0·00005 *M*), the force-area curve for the monolayer is changed. The sudden increase in slope of the curve now occurs at a larger area than before. The effect of adenosine triphosphate is highly specific, as adenosine diphosphate, and inorganic tripolyphosphate, pyrophosphate and orthophosphate employed in the same molar concentrations have no visible effect. Only on addition of these substances in concentrations approximately ten times higher are similar effects obtained. Owing to the uncertainty in the dry-weight determinations, too much emphasis should not be laid on the absolute values of the area in the diagram.



Force-area curves for actomyosin
●—●—●, without adenosine triphosphate
○—○—○, 0·05 mgm. per ml. adenosine triphosphate

The data obtained in several experiments indicate that the expanding effect is more pronounced with monolayers of myosin proper than with those of actomyosin. In the latter the area at zero compression increases after addition of adenosine triphosphate by about 30 per cent, whereas in the case of myosin proper the average increase amounts to 100 per cent. In both cases the gradient of the approximately rectilinear part of the curve decreases when adenosine triphosphate is added. Actin shows no reaction with adenosine triphosphate or the other phosphate compounds investigated.

The result indicates that adenosine triphosphate in some way combines with myosin and causes it to expand, thereby increasing the surface pressure of the monolayers in the condensed state. According to a verbal communication from Dr. D. F. Cheesman, it is probable that the effects described above may be due rather to the spreading kinetics of myosin than to the properties of the fully spread films.

My thanks are due to Prof. E. K. Rideal and Dr. D. F. Cheesman, of the Davy Faraday Laboratory at the Royal Institution, London, for hospitality and valuable advice. The preliminary experiments of the investigation were made in that Laboratory.

PARAMAGNETIC RESONANCE IN COPPER SULPHATE

Experimental Investigation

INVESTIGATIONS of paramagnetic resonance in salts of the iron group of transition elements at centimetre wave-lengths have shown that it is possible to obtain detailed information about the lowest energy-levels of the paramagnetic ion by these methods[1]. We have investigated at room temperature the resonance absorption in single crystals of copper sulphate ($CuSO_4.5H_2O$) at wave-lengths of 3·04 cm., 1·23 cm. and 0·85 cm. in a magnetic field. The results show two features of considerable interest: first, that under certain conditions the absorption line is very much narrower than would be expected from the normal magnetic interaction of the ions; and secondly, that at the longer wave-lengths only one line is found, whereas theoretically two lines should appear at certain orientations of the crystal in the external magnetic field. In fact, it is only at 0·85 cm. wave-length that the two lines are just resolved.

The measurements are made by placing a section of a single crystal at the bottom of a cylindrical H_1 resonator placed in a magnetic field at right angles to the high-frequency magnetic field. The magnification factor Q of the resonator is then measured for various values of the magnetic field.

Crystallographic data[2] show that there are two non-equivalent cupric ions in the unit cell, each surrounded by four water molecules and two oxygen atoms, in a nearly octahedral arrangement. The crystalline electric field acting on an ion is mainly of cubic symmetry with a component of tetragonal symmetry, the tetragonal axis being in the direction of the oxygen atoms and the angle between the tetragonal axes of the two ions being about 80°.

On this basis Polder[3] has calculated the energy-levels of the basic spin doublet in a magnetic field and hence the susceptibility of the salt, and these calculations are in good agreement with Krishnan's experimental work[4] on the susceptibility. The energy difference between the two spin-levels in a magnetic field H may be expressed as $g\beta H$, where β is the Bohr magneton and g depends on the orientation of the tetragonal axis with respect to the magnetic field. Thus the resonance absorption should occur when $g\beta H = h\nu$. Some of the experimental results are given in the accompanying table.

Direction of H	L_1 (154°, 64°, 51°)			L_2 (78°, 130°, 52°)				L_3		
Wave-length (cm.)	3·04	1·23	0·85	3·04	1·23	0·85		3·04	1·23	0·85
H at resonance Kg	3·36	8·36	12·1	3·11	7·76	10·6	11·9	3·10	7·75	11·2
g	2·09	2·08	2·08	2·26	2·26	2·37	2·12	2·27	2·26	2·26
g (susceptibility)	2·06	2·06	2·06	2·27	2·27	2·47	2·06	2·27	2·27	2·27
Width $\Delta H_{1/2}$ gauss	28	24	25	115	640		$\simeq$ 450	58	50	—

The orientation of the external magnetic field with respect to the crystallographic axes is denoted by L_1, L_2 and L_3. L_1 is the direction at right angles to the tetragonal axes of both ions, L_2 is along one of the tetragonal axes and L_3 is a bisector of the angle between the two axes. (The angles which L_1 and L_2 make with the crystallographic axes are also given.)

The main features of the results may be summarized as follows. (1) The g values are in good agreement with those obtained from susceptibility measurements, but theoretically there should be two lines when H is along L_2. In this case H is nearly at right angles to the tetragonal axis of one copper ion, which should therefore have the same g value as when H is along L_1 (that is, 2·06). The g value of the other ion should be 18 per cent higher, the mean value of the two ions being equal to that given by the susceptibility measurements. That the appearance of only one line is not due to lack of resolution is shown by the fact that at 3·04 cm. the two lines should be about 500 gauss apart, whereas the width ($\Delta H_{1/2}$) of the line is only 115 gauss. At 0·85 cm. wave-length, however, the two lines are just resolved.

(2) The width $\Delta H_{1/2}$ given here is the difference in magnetic field between the position of maximum absorption and that at which the absorption is half its maximum value. This width varies very greatly both with orientation and with wave-length. One cause of broadening of the line is the fluctuating magnetic field due to neighbouring dipoles. The effective internal field due to this is about 370 gauss in copper sulphate, and therefore the width of the line should be of this order, whereas for H along L_1 the width is only 25 gauss.

Van Vleck and Gorter[5] have suggested that this narrowing of the line may be due to the effect of exchange forces between the copper ions, and a qualitative description of the other results may be given on this basis as follows. When H is along the tetragonal axis of one of the copper ions, the values of g, and therefore the precessional frequencies of the two ions, are different. If there is exchange between the ions, the type of absorption curve obtained will depend on whether the exchange frequency is greater or smaller than the difference in the precessional frequencies. When it is larger, a mean value of the energy of the two copper ions should be measured, whereas when it is smaller each ion should be observed separately and two lines should appear. A rough estimate of the exchange frequency can be made from the fact that at 1·23 cm. the two lines are just not resolved. The difference in frequency of the two lines at constant H would be about 0·15 cm.$^{-1}$, which is therefore the order of the exchange frequency.

On this theory the maximum width should occur when the difference between the values of g of the two ions is a maximum, that is, with H very nearly parallel to one of the tetragonal axes, and this is found experimentally. Also the minimum width should be when the two values of g are equal, for example, in the plane containing L_1 and L_3. This is also found experimentally, although the width is not constant in this plane, varying from 25 gauss along L_1 to 60 gauss along L_3. A quantitative theory of the broadening due to exchange of dissimilar ions is given in the following communication by Prof. M. H. L. Pryce.

The behaviour of copper sulphate crystals may be contrasted with that of potassium – copper sulphate ($CuSO_4.K_2SO_4.6H_2O$), in which two lines are observed[6] when H is in the appropriate direction, the values of g being in close agreement with theory. The exchange frequency in this salt is therefore very considerably smaller.

It might be expected that there would be some connexion between the exchange energy measured in this way and the specific heat anomaly found in copper sulphate crystals at about 1° K. but not found in the potassium – copper salt[7]. The order of magnitude of the exchange energy is some five times too small, but presumably exchange between like ions should contribute to the specific heat, whereas only the exchange between dissimilar ions is effective in the problem discussed here.

Details of these measurements will be published in the near future.

Theory

In many paramagnetic crystals the resonance absorption of microwaves in the presence of a transverse magnetic field spreads over a range of a few hundred gauss, and this can be accounted for by the magnetic interaction between the ions. There are certain substances, however, of which copper sulphate is an example, in which the resonance is sharper than can be explained in this way, and it has been suggested that the sharpness is due to electron exchange[1]. Gorter and Van Vleck[2] have reported the result of a calculation which shows that, while the mean square spread is unaffected by exchange, the mean fourth power spread is increased, indicating a sharpening of the peak together with an enhanced absorption in the wings of the resonance. That such an effect is to be expected can be seen from the following qualitative argument.

The effect of exchange can be described as an interchange of the spins of the ions with a frequency spectrum determined by the magnitude of the exchange energy. If this frequency is high compared with the spread of precession frequencies of the ions in the applied magnetic field, due to the random orientation of the magnetic field of neighbouring ions (the internal field), the latter will fluctuate so rapidly that only an average value will be effective. The statistical weight of states in which the average is comparable to the instantaneous internal field is relatively small, and the net effect will be to reduce the breadth of the resonance. The effect is similar to the sharpening of nuclear paramagnetic resonances in liquids due to the rapid molecular motions[3].

The observations on copper sulphate[4] are consistent with the hypothesis that the breadth due to magnetic interaction, reduced by exchange in this way, is only about 25 gauss; but that there is, in addition, a broadening caused by the exchange of electrons of cupric ions having different principal magnetic axes, and that this is the main cause of broadening of the resonance, except for certain orientations of the applied field.

There are two non-equivalent sets of cupric ions in hydrated copper sulphate ($CuSO_4.5H_2O$), distinguished by different orientations of the neighbouring oxygen atoms and water molecules. Polder[5] has shown that the magnetic behaviour is well accounted for by the action on the cupric ions of a crystalline field composed of a part with cubic symmetry and one with tetragonal symmetry. Each ion (spin $\frac{1}{2}$), in its ground state, is magnetically uniaxial. In susceptibility measurements copper sulphate is anisotropic with three principal axes as follows: (1) along the direction perpendicular to the principal axes of the two types of ion; (2) and (3) along the bisectors of the angles between them. There is, however, a slight discrepancy between the calculated susceptibilities and the observations of Krishnan and Mookherji[6], which may indicate that a single ion is not exactly uniaxial.

In view of the smallness of the magnetic broadening, it is reasonable to attempt a calculation of the broadening in which only the exchange effect is considered, and the magnetic interaction is ignored. The exchange energy will be assumed to be of the usual 'isotropic' type and not of the 'anisotropic indirect' type discussed in a recent paper by Opechowski[7]. Had the ions all been equivalent, the exchange would have caused no broadening. One may therefore try to treat the slight difference between the ions as a perturbation, and expect reasonably correct results provided the difference in magnetic energy of the two kinds of ions, when they have the same spin orientation, is small compared with the exchange energy. This condition is equivalent to saying that the frequency must be small compared with the frequency at which the absorption curve first shows two resolved peaks, corresponding to the different effective moments of the two kinds of ion: this frequency is about 1 cm.$^{-1}$ for copper sulphate. Alternatively, for higher frequencies, one may treat the exchange interaction as a perturbation. The experimental material available at present refers more nearly to the former condition, and the present note deals only with results calculated on this approximation.

The magnetic energy of a single ion in a magnetic field **H** can be written

$$E_{\text{magn}} = \mu s.\mathbf{g}.\mathbf{H},$$

where s is the spin angular momentum divided by $\hbar$, **g** is a tensor the principal values of which are the *g*-values in the principal directions of the ion and μ is the Bohr magneton. For the spin system in a crystal, the total energy can be written

$$\begin{aligned} E &= \mu\,\mathbf{S}'.\mathbf{g}'.\mathbf{H} + \mu\,\mathbf{S}''\mathbf{g}''\,\mathbf{H} + E_{\text{ex}},\\ &= \tfrac{1}{2}\mu(\mathbf{S}' + \mathbf{S}'').(\mathbf{g}' + \mathbf{g}'').\mathbf{H} + E_{\text{ex}} +\\ &\qquad \tfrac{1}{2}\mu\,(\mathbf{S}' - \mathbf{S}'').(\mathbf{g}' - \mathbf{g}'').\mathbf{H}, \end{aligned} \tag{1}$$

where **S** refers to the total spin of ions of one type, and the superscripts ′ and ″ refer to the two types of ion. E_{ex} is the exchange energy of the system. The third term in (1) is treated as a small perturbation.

If the third term were absent, the energy would be the sum of two commuting parts, and the eigenvalues would be the sum of the eigenvalues of the parts. An oscillating transverse field would cause transitions between states the spin of which in the direction of $(\mathbf{g}' + \mathbf{g}'').\mathbf{H}$ differs by one unit, and which have the same value of the exchange energy. The system would have a single sharp absorption frequency

$$\mu\,|\,(\mathbf{g}' + \mathbf{g}'').\mathbf{H}\,|\,/2h.$$

The effect of the perturbation term, which expresses the difference between the ions, is threefold:

(*a*) It changes the energy-levels of the system, and hence the energy difference of levels connected by the above selection rule. The absorption now takes place over a range of frequencies (for a fixed magnetic field, or conversely, for a fixed frequency, over a range of magnetic field). This is the main effect. The shape of the line from this cause may be expected to be roughly a Gaussian curve.

(*b*) It introduces into the eigenfunctions admixtures of wave functions belonging to other eigenvalues of the exchange energy, thereby allowing weak transitions to states excluded by the original selection rule. This is most marked for states differing only slightly in exchange energy, and gives rise to a 'tail' on the absorption curve, falling off roughly inversely as the square of the distance from resonance. It may also give rise to enhanced absorption at low frequencies and at twice the resonant frequency. This effect increases with magnetic field.

(*c*) The coupling with the oscillating field being unsymmetrical with respect to the variables of the two types of ion, transitions can be induced to states of different exchange energy. This effect is similar to (*b*), except that it shows no marked preference for small differences of exchange energy and is roughly independent of H. It gives a background of non-resonant absorption.

A straightforward application of second-order perturbation methods (the first-order effect is zero) leads to the following expression for the dependence of effect (*a*) on orientation and frequency. Using a notation in which l_1, l_2, l_3 are the cosines of the angles between the magnetic field and the principal magnetic axes, and g_1, g_2, g_3 are the principal g-values, the breadth ΔH_{ex} due to exchange, for fixed frequency ν, is given by

$$\Delta H_{\text{ex}} = \frac{C\nu^2 \begin{bmatrix} 4(g_2+g_3)^4 l_2^4 l_3^4 \\ -4A(\nu)(g_2+g_3)^2 l_2^2 l_3^2 \{g_1^2 l_1^2 (l_2^2+l_3^2) + (g_2 l_2^2 - g_3 l_3^2)^2\} \\ + B(\nu)\{g_1^2 l_1^2 (l_2^2+l_3^2) + (g_2 l_2^2 - g_3 l_3^2)^2\}^2 \end{bmatrix}^{1/2}}{[g_1^2 l_1^2 + g_2^2 l_2^2 + g_3^2 l_3^2]^{5/2}} \qquad (2)$$

where C is a constant depending on the magnitude of the exchange energy but independent of orientation, temperature and frequency, and $A(\nu)$, $B(\nu)$ are independent of angle and temperature, and tend to 1 in the limit of low frequencies (small compared with the exchange frequency, that is, about 0·15 cm.$^{-1}$).

The breadth is to be interpreted as a root mean square deviation from the centre of resonance. In comparing with experiment it should be noted that it refers to the Gaussian part of the peak and ignores the tail. The formula will vary in a more complicated manner with orientation if the individual ions are not uniaxial, but will involve the frequency in the same way.

If one wishes to include the effect of magnetic interaction one may, as a rough estimate, make the assumption that the square of the total breadth is the sum of squares of partial breadths

$$(\Delta H)^2 = (\Delta H_{\text{ex}})^2 + (\Delta H_{\text{magn}})^2$$

and suppose that ΔH_{magn} is not very sensitive to orientation.

It is to be emphasized that (2) is valid only for frequencies small compared with 1 cm.$^{-1}$, and provided $\mu H \ll kT$.

ROYAL OBSERVATORY, GREENWICH

The Report of the Astronomer Royal to the Board of Visitors of the Royal Observatory, Greenwich, read on the occasion of the annual visitation of the Observatory on June 5, covers the period May 1, 1947–April 30, 1948, and the state of the Observatory mentioned in various parts refers to the latter date. Although a large amount of the report deals with the usual routine work, certain portions are concerned with the grave difficulties that have arisen in the post-war period, which may not be completely overcome for several years. This short synopsis of the report will deal chiefly with these difficulties.

Stage 1, as it is called, of the move to Herstmonceux was arranged to take place in August and was intended to include the Nautical Almanac Office, the Chronometer Depot, the Magnetic and Meteorological Department, and the secretariat; the Solar Department will wait until the new Solar Building is ready. Even under normal conditions, the removal would have entailed considerable disorganisation to the work of the Observatory; but this disorganisation is greatly increased by the difficulties in the present conditions. No provision has been made in the estimates for the current financial year for the completion of Stage 1 of the move, and the output of the Observatory is necessarily curtailed with every month of delay. As might be expected, some of the instruments are not in use, and there has been great disappointment regarding the performance of one in particular, about which something will be said later.

The 28-in. and 26-in. domes are in a bad state of repair, and it is doubtful whether either is suitable for transfer to Herstmonceux; until this point has been settled, no work on them will be undertaken. The 28-in. and 26-in. telescopes were dismounted in the autumn of 1947, and the former, with the exception of the lens and some minor parts, was transported by road to Herstmonceux, where it is stored in a brick hut. The necessary parts of the drive have been sent to Sir Howard Grubb, Parsons and Co. for alteration to a synchronous motor drive. Practically all the 26-in. telescope has been sent to the same firm, as it was decided that roller bearings in both axes should be inserted. The objectives of these telescopes are still in good condition and remain for the present at Greenwich.

The mirrors of the 36-in. Yapp reflector were aluminized in May 1946; but the instrument remained unused until November. In December the 36-in. mirror was given a light alcohol wash and was then found to be in poor condition. It was used until March 1948, when it was discovered that several areas each about two inches across had lost all their coating, and after a fresh wash, the reflexion coefficient was estimated to be as low as about 30 per cent. The mirror was cleaned and silvered; but surface blemishes remained visible on the glass even after silvering and it is not certain how much of this can be attributed to poor aluminizing and how much to the deposit of chemically active dirt. It is interesting to know that the Cassegrain mirror was, and still is, in good condition, and the contrast between the two mirrors confirms what has been already known from other pairs of aluminized mirrors, one facing up and one down, in the conditions which prevail at Greenwich. The expense and delay involved in sending the mirror away to be aluminized are not warranted while the mirror remains at Greenwich; but as the spectrograph is primarily for use in the ultra-violet region, the effectiveness of the telescope is very much reduced. When an aluminizing plant capable of handling the 36-in. reflector is installed at Herstmonceux, this state of affairs will be remedied, and this is just one among many reasons for accelerating the move to Herstmonceux.

If there be any who expect a greatly increased output from the Observatory in the near future, they will be disillusioned when they read the present report. It is emphasized that the situation which will prevail from the end of Stage 1 until completion of the move will be very disadvantageous in many ways, not least of which will be the marked excess of observers over instruments at Herstmonceux and Abinger. Many valuable years of potential training have been lost already; old observers are retiring and a new and inexperienced staff is increasing. Even if the dismemberment of the Greenwich Observatory could be effected immediately, much ground would have to be made up, and the longer the delay in unification the more serious will be the effects on the standards of observational skill. This is a matter which requires immediate consideration from the authorities, and another matter is of equal or even greater urgency.

While the hostel arrangements will cater reasonably well for the unmarried staff, no arrangements have yet been made for married men. It is almost certain that most married members of the staff, some of whom have had as much as six years war experience, will be faced with a period of at least a year's separation from their families. The continuance of a similar situation through all the later stages of the move must cause grave dissatisfaction and discouragement, and would have an adverse effect on the smooth running of the Observatory. The Astronomer Royal has proposed to the Admiralty that houses should be provided for the senior observing staff, and the necessity for such accommodation, which is fairly normal for observatories, is obvious to everyone who knows that the Observatory at Herstmonceux is in an isolated area. Such provision on the edge of the Observatory property would greatly facilitate the night duties of the observing staff and also reduce the loss of observing hours. It is pointed out that it may be difficult to fill the additional vacancies for senior scientific workers which will occur later, because it is highly probable that many married men will refuse an offer which implies separation from their families. In the words of the Astronomer Royal: "There is evidently a grave risk that the increase in complement, which has been approved in principle, may be nullified in practice through an unrealistic approach to the housing problem, quite apart from the general hardship which is, as yet, the only prospect for existing married staff of the later stages".

The report devotes a little more than a page to the Isaac Newton Observatory which will be erected in the grounds at Herstmonceux. Among the types of observation to be undertaken with the 100-in. telescope are the following: stellar spectroscopy and spectrophotometry, star counts, galactic structure, the investigation of the distribution and extent of obscuring material, spectral classification with a slitless telescope, the determination of radial velocities, and observations of extra-galactic nebulæ. Details regarding optical design are still under consideration, and information will be obtained about the system of control which has been developed for the 200-in. telescope, and also on the methods of driving and control of other large telescopes. Messrs. Pilkington Bros., Ltd., have carried out investigations on the manufacture of large glass mirror disks, and it is proposed to make the 100-in. disk of 'Pyrex' glass and to cast it as a solid disk, the lower face being given a concave curvature of approximately the required amount. It is expected that the casting will be undertaken about March 1949.

The magnetic elements as determined at Abinger for 1947 and also the three preceding years are as follows:

Year	Declination (West)	Horizontal intensity	Vertical intensity	Inclination
1944	10° 07·8′	0·18566	0·43189	66° 44·3′
1945	9 59·5	0·18573	0·43207	66 44·3
1946	9 51·1	0·18569	0·43235	66 45·4
1947	9 43·1	0·18577	0·43246	66 45·2

At the time of writing the above summary of the Astronomer Royal's Report, it was known that there had been a delay in carrying out Stage 1 of the movement to Herstmonceux.

RESISTANCE TO SULPHADIAZINE AND 'PALUDRINE' IN THE MALARIA PARASITE OF THE FOWL (*P. gallinaceum*)

By DR. ANN BISHOP
AND
ELSPETH W. McCONNACHIE
Molteno Institute, University of Cambridge

Acquired Resistance to Sulphadiazine

RECENTLY Bishop and Birkett[1], and Williamson, Bertram and Lourie[2], working independently, have described the development of resistance to the antimalarial drug 'Paludrine' in infections of *Plasmodium gallinaceum* in young chicks. This resistance developed rapidly and increased forty-fold within about four and a half months. With sulphadiazine and quinine, however, Williamson and his co-workers obtained no acquired resistance in *P. gallinaceum*, though the periods of drug treatment extended over two and a half years. Since the publication of their results, Knoppers[3] has described a twofold increase in resistance to quinine in the same species of avian malaria. Bishop and Birkett[4] found that resistance to sulphadiazine could be produced in *P. gallinaceum* in young chicks by methods similar to those with which they had induced resistance to 'Paludrine', though its development was relatively slow and the degree of resistance obtained was not great.

As a result of further treatment with gradually increasing doses of sulphadiazine, we have now obtained a strain of *P. gallinaceum* in young chicks in which the resistance to the drug is thirty-two times greater than that of the untreated strain. Whereas the minimum dose of drug which produces an adverse effect upon the growth-rate of the normal strain, when given twice daily on successive days, is 0·625 mgm./20 gm. of body-weight, in the resistant strain growth of the parasites occurs in birds receiving

20 mgm. twice daily*. It took approximately twelve months to produce this thirty-two-fold resistance to sulphadiazine. The degree of resistance acquired has been assessed at intervals, by comparing the intensities of infections produced by standard inocula (that is, 50,000,000 parasites per chick intravenously) of (*a*), the resistant strain, into groups of chicks receiving doses ranging from 2·5 to 20 mgm. of sulphadiazine twice daily for three-and-a-half days, and (*b*), the normal parent strain, into groups of chicks receiving similar drug treatment. The sulphadiazine-resistant strain produced infections in chicks receiving doses of drug which inhibited the development of the normal strain (that is, 2·5–20 mgm.); but the resulting infections were not as heavy as those produced by the parent strain in untreated birds. The sulphadiazine-resistant strain produced, on the whole, less intense infections in untreated birds than did the parent strain.

In the sulphadiazine-resistant strain of *P. gallinaceum*, exoerythrocytic schizonts were found in chicks during treatment with this drug.

We have proved that this sulphadiazine-resistant strain of *P. gallinaceum* is also resistant to sulphathiazole, sulphanilamide and sulphapyridine.

Bishop and Birkett[1,4] found that in *P. gallinaceum* resistance to 'Paludrine' was retained after five passages through mosquitoes without intervening drug treatment. On two different occasions *P. gallinaceum*, resistant to twice-daily doses of 5 mgm. of sulphadiazine, was passaged through *Aëdes œgypti* and afterwards tested, without intervening drug treatment, by the method outlined above: no loss in drug-resistance was observed. Williamson and his co-workers also observed no loss in resistance to 'Paludrine' after one mosquito passage; but, according to Knoppers[3], acquired resistance to quinine, in the same species of avian malaria, was partially lost after one mosquito-passage.

Experiments by Emerson and Cushing[5] upon acquired resistance to sulphonamides in *Neurospora* suggest a possible explanation of the discrepancy between the results of experiments upon the effect of mosquito transmission. In this organism, as in *P. gallinaceum*, resistance to sulphonamides arises by successive stages. In *Neurospora* the first adaptations to the drug do not involve a genetic change; but gene mutation appears later, after further drug treatment, in the more fully adapted strain. The resistance to quinine described by Knoppers was comparatively slight, being only twofold. In the light of Emerson and Cushing's observations, it is possible that this resistance might be due only partially to gene mutation, and that the degree of drug adaptation not genetically controlled might be lost during development in the mosquito in the absence of the drug. In strains of *P. gallinaceum* in which drug adaptation is more complete, for example, the 'Paludrine'- and sulphadiazine-resistant strains, the drug-resistance may be due wholly to the selection of drug-resistant mutants, with the result that no loss in resistance occurs during the sexual cycle in the mosquito.

Cross-resistance to Sulphadiazine and 'Paludrine'

The work of Bishop and Birkett[1,4], Williamson, Bertram and Lourie[2], and Williamson and Lourie[6] has shown that 'Paludrine'-resistant strains of *P. gallinaceum* are normally sensitive to quinine, 'Pamaquin' and 'Mepacrine', but resistant to the methyl homologue of 'Paludrine', N′-*p*-chlorophenyl-N^5-methyl-N^5-*iso*propylbiguanide. Williamson and his co-workers found that acquired resistance to 'Paludrine' did not confer resistance to sulphadiazine or to pyrimidine precursors of 'Paludrine' (for example, 3349, 2-*p*-chlorophenylguanidino-4-β-diethylaminoethylamino-6-methyl-pyrimidine), and they failed to produce strains of *P. gallinaceum* resistant to 3349.

The sulphadiazine-resistant strain of *P. gallinaceum*, when tested by the method described above, was found to be resistant to 0·1 mgm. of 'Paludrine' (the minimum dose which, when given twice daily, will suppress an infection of the normal strain of *P. gallinaceum*) although it had not been subjected to treatment with that drug.

Further tests for resistance to 'Paludrine' were made with two sulphadiazine-resistant strains of *P. gallinaceum* of more recent origin. These strains, *strain A* and *strain B*, had been isolated eleven weeks previously from the normal untreated parent strain, which was tested simultaneously for resistance to 'Paludrine' and found to be normally sensitive to the minimum effective dose (0·1 mgm.). *Strain A* was passaged twenty-two times during eleven weeks through birds receiving doses of sulphadiazine gradually increasing from 0·625 mgm. to 5 mgm. This treatment was similar to that by which resistance had been induced in the original sulphadiazine-resistant strain. *Strain A* was then tested and proved to be resistant, not only to 1·25 mgm. and, to a lesser extent, 5 mgm. doses of sulphadiazine, but also to 0·1 mgm. and 0·5 mgm. doses of 'Paludrine'.

Strain B, of identical origin to *strain A*, was treated with 5 mgm. doses of sulphadiazine for the eleven-week period. Whereas in *strain A* the infection in the passage birds was acute throughout the whole period of drug treatment, in *strain B* it was allowed to become chronic, passage into new chicks being performed only four times during the eleven weeks. The method by which the strains were maintained in the chicks did not, however, appear to be significant in the development of 'Paludrine'-resistance, as *strain B*, when tested simultaneously with *strain A*, against 0·1 and 0·5 mgm. doses of 'Paludrine', also proved to have become resistant to this drug. Though their reaction to 'Paludrine' was similar, these two strains differed in the degree of resistance to sulphadiazine which they had acquired. Whereas *strain B* was definitely resistant to 1·25 mgm. of this drug, it showed much less resistance to 5 mgm. doses than did *strain A*; but after further treatment with 5 mgm. doses of sulphadiazine, *strain B* acquired a resistance to this dose comparable to that of *strain A*. As yet, these strains have not been tested for resistance to 'Paludrine' in doses greater than 0·5 mgm.

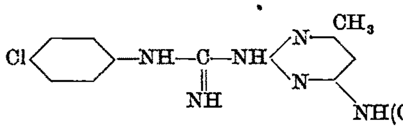
As acquired resistance to sulphadiazine was found to confer resistance to 'Paludrine', the effect of sulphadiazine upon a 'Paludrine'-resistant strain of *P. gallinaceum* was studied. This strain had been in contact with 'Paludrine' for more than eighteen months and had been passaged at frequent intervals, for more than twelve months, through chicks receiving the maximum tolerated dose (1·0 mgm. twice daily) almost daily throughout this period. When tested with doses of 1·25 mgm. of sulphadiazine, it was found to be resistant to this drug also. Whether this 'Paludrine'-resistant strain is resistant to higher doses of sulphadiazine has not yet been ascertained.

As the sensitivity of the 'Paludrine'-resistant strain to sulphadiazine had not been tested previously, it is not known whether resistance to both drugs developed simultaneously, as in the case of the sulphadiazine-resistant strains *A* and *B*, or whether resistance to sulphadiazine developed only after prolonged treatment with 'Paludrine'. That the latter alternative is the more probable is shown by the following observations. The untreated parent strain of *P. gallinaceum* was tested with 1·25 mgm. doses of sulphadiazine and found to have a normal sensitivity to this compound. A substrain was then passaged at intervals of two to three days through chicks treated with doses of 'Paludrine' increasing from 0·025 to 0·2 mgm. After ten weeks treatment the strain was proved to be resistant to 0·5 mgm. doses of 'Paludrine', a dose greater than that with which it had been treated previously, but its sensitivity to the minimum effective dose of sulphadiazine was unchanged. In this strain, therefore, the development of resistance to 'Paludrine' was not accompanied by resistance to sulphadiazine. The strain is being treated further with larger doses of 'Paludrine' in order to discover if, and when, sulphadiazine-resistance develops. The fact that sulphadiazine-resistance did not develop simultaneously with resistance to 'Paludrine' in 'Paludrine'-treated birds, but only appeared in a strain subjected to prolonged treatment with the maximum tolerated dose of 'Paludrine', would explain the failure of Williamson and his co-workers[2,6] to observe resistance to sulphadiazine when their 'Paludrine'-resistant strain was treated with this drug, as their strain had been subjected to 'Paludrine' for a much shorter period than had ours.

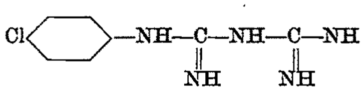
---

* Throughout this account, the doses of drug are expressed in mgm./20 gm. of body-weight of chick. The doses were given twice daily. The chicks used were four to fourteen days old at the beginning of treatment.

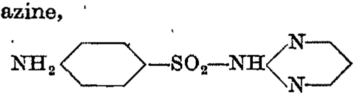
Williamson and his co-workers[2] suggest that the presence or absence of a pyrimidine ring in such compounds as 3349



and 'Paludrine'



may be a factor in determining drug-resistance. Sulphadiazine,



however, also contains a pyrimidine ring, and we have now shown that it, like 'Paludrine', forms drug-resistant strains of *P. gallinaceum* and that resistance between it and 'Paludrine' is reciprocal. On the other hand, Williamson and his co-workers[2] failed to produce resistance to 3349, which has a pyrimidine ring. In these compounds, therefore, the presence or absence of the pyrimidine ring does not appear to determine the formation of drug-resistant strains of *P. gallinaceum*.

It has been shown by Maier and Riley[7] in *P. gallinaceum* and by Marshall and his co-workers[8] in *P. lophuræ* that the antimalarial action of sulphonamides is inhibited by *para*-aminobenzoic acid. We have confirmed this observation on our strain of *P. gallinaceum*; but preliminary experiments suggest that the action of 'Paludrine' is not antagonized by this compound. The demonstration of cross-resistance between 'Paludrine' and sulphadiazine, two compounds of great importance therapeutically, presents a very interesting problem regarding the mechanism of their antimalarial action.

The work has been financed by the Medical Research Council. We are indebted to the Imperial Chemical (Pharmaceuticals), Ltd., for the 'Paludrine' and to Messrs. May and Baker, Ltd., for the sulphonamides.

CHANGING ASPECTS OF NUTRITION

SECTION I (Physiology) of the British Association devoted the morning session on September 9 to a discussion of "The Changing Aspects of Nutrition". Prof. J. R. Marrack introduced the subject with a review of work done on the relation of nutrition to infection. He pointed out that we are uncertain which nutrients are particularly involved in defence against infection and how the defences are weakened by malnutrition, particularly in human beings. In experimental animals deprived of vitamin A the ciliated columnar epithelium of the respiratory passages undergoes keratinizing metaplasia. Bacteria that get into the passages are not cleared out by cilia, and the passages are blocked by desquamated cells. In consequence the animals are liable to get broncho-pneumonia. It is not known how frequently this keratinizing metaplasia occurs in the respiratory passages of human beings. When it is found, the nutritionist ascribes it to lack of vitamin A, whereas the morbid anatomist thinks that it is caused by inflammation or irritation.

In the discussion, Dr. H. M. Sinclair said that he had seen bronchiectasis in Holland, which was attributed to lack of vitamin A. In experiments in which human beings have been deprived of vitamin A for more than a year, the subjects were not abnormally liable to respiratory infections; nor do large supplements of vitamin A appear to reduce the frequency or severity of colds.

Cannon and his school have found that the formation of antibodies is impaired in animals that are severely depleted of protein. Gell has recently shown that very ill-nourished Germans formed less antibodies in response to injections of antigens than were formed by well-fed British soldiers. But protein is not the only nutrient that is involved in the formation of antibodies, and other defences are impaired in malnourished animals.

Prof. Marrack suggested that the infecting organisms of those diseases, to which resistance seems to be increased by malnutrition, are exacting organisms that invade the cells of the host. When the host lacks some nutrient, such as vitamin B_1, the metabolism of the host's cells may be so altered that they are no longer congenial to the invader.

Dr. J. W. Howie described experiments designed to show the effects of the less-severe degrees of malnutrition. The number of eggs of parasitic worms was counted in the fæces of a group of ewes fed on pasture and of another group that were given a protein rice concentrate. After a year there were much fewer eggs in the fæces of the group that were given the concentrate. One group of Swiss white mice were given a stock diet and another diet that supplied more protein and calcium. Suspensions of human tubercle bacilli were injected intravenously. In the group that had the higher protein ration, the mean survival time was longer and the extent of invasion of the lungs less than in the group that had the stock diet.

Prof. A. Fleisch discussed the effect of rationing in Switzerland as a large-scale experiment on human requirements. Up to 1943, when rations supplied little more than 2,000 calories a day to a normal adult, health improved, there was less dental caries and weights were maintained. During the period of rationing the amounts of meat in the diet fell and the amounts of potatoes and vegetables rose; the amounts of calcium, niacine, vitamin B_1, and ascorbic acid in the diets were considerably higher than before. When the number of calories fell below 2,000 in 1944 and 1945, weights of adults and children fell, and the hæmoglobin level of a sample group, which was studied over the whole period, fell. Prof. Fleisch thought that the League of Nations standard of requirements for a sedentary adult is unnecessarily high.

Dr. B. S. Platt discussed practical applications of the knowledge of nutrition and the social aspects of nutrition in villages of Central and West Africa. The estimated expenditure of energy was low and approximately equal to consumption. The yields of food crops were low and would barely supply the calories required. In West Africa nutrition suffered more, as groundnuts were grown for sale, and less food could be grown for home consumption. Much time was lost in collecting and preparing food and in drawing water. The problem is to build a new social structure in place of the native structure which is breaking down.

INTERNATIONAL COMMISSION ON LARGE DAMS

CONGRESS IN SWEDEN

THE third Congress of the International Commission on Large Dams was held in Sweden during June 10–17. The opening session was held in the Stockholm Concert Hall (Konserthuset) and the closing session at the Saga Cinema, Trollhättan. At the opening session Mr. G. Westerburg, president of the Swedish Committee of the International Commission on Large Dams, welcomed the delegates from twenty-three nations, and M. A. Coyne, president of the Commission, declared the Congress open.

There were four plenary sessions dealing with the following technical questions:

(1) Critical exposition of the measurement of uplift pressures and stresses arising therefrom; M. W. Schurter, Inspecteur fédéral et chef des Travaux Publics de la Confédération Suisse, acting as general reporter.

(2) Research methods and instruments for the measurement of stresses and deformation in earth and concrete dams; M. Mary, ingenieur en chef des Ponts et Chaussées, France, acting as general reporter.

(3) The most recent precautions to avoid the formation of pipings; Prof. K. Terzaghi of Harvard University, Cambridge, Mass., acting as general reporter.

(4) Experiences arising from the testing and the actual use of special cements for large dams; Prof. B. Hellström, of the Royal Institute of Technology, Stockholm, acting as general reporter.

More than seventy papers ranging over these subjects were presented for discussion, and most of these were available before the meeting and were accompanied by summaries in French and English.

The question of upward water pressure on dams, and what allowances should be made for it, is a problem which has worried designers of new dams for a great many years. The information needed is not only the value per unit surface area of the upward pressure to be allowed in calculations, but also some idea of the extent of the area of the dam over which such upward pressure operates. Of the eleven papers submitted, three, by Harza (U.S.A.), Leliavsky Bey (Egypt) and McHenry (U.S.A.), dealt with the scientific aspects of the problem and arrived at the general conclusion that, within the limits of error of measurement, the upward pressures act on practically the whole geometrical surface in question, whatever their specific values at particular points, whether in a plane intersecting the dam, or in the plane of the foundation. Seven other papers dealt with uplift pressures from the practical point of view, five describing the experimental determination of uplift pressures in existing structures, and two dealing with the influence such pressures have on the design of masonry or concrete dams, particularly with regard to the stresses induced. On the upstream side, the value of the specific upward pressure is equal to the hydrostatic pressure of the water in the reservoir, while on the downstream side it is normally zero. Between these two extreme edges of the cross-section, the uplift pressure varies generally in a linear manner, allowing, of course, for the effect of any structural measures designed to reduce the intensity of the pressure. Needless to say, appropriate structural measures should be adopted to prevent the upward pressures becoming operative in the base of the dam, on the foundation surface, or in the body of the dam itself. The remaining paper in this group, presented by Prof. Myslivec, of Prague, dealt with the important problem of infiltration through earthwork embankments, and with the properties of suitable sealing materials for these.

Nineteen papers were submitted on the second question dealing with research methods and instrumentation. They ranged over many and varied topics such as the measurement of displacements of the soil and of earthworks, the measurement of the pressure of water contained in earthworks, temperature and shrinkage measurements, the deformation of gravity dams and arch dams, and the settlement of earth and rock fills. The reports also provided a useful comparison of the experimental methods and measuring equipment used in different countries. Of particular interest and significance were the observations of the swelling of the soil due to impregnation by water after filling the dam, made by Farnsworth (Australia), on the Nepean Dam, and by André Nizery (of France) on the Sautet and Querlédan Dams.

The phenomenon of piping and seepage provided the subject for fifteen papers in the third group. A dam may fail by piping in two different ways: either the seepage pressure exerted by the percolating water may cause a failure of the soil beneath the dam; or the soil may be removed from beneath the dam by erosion, in which case a tunnel-shaped passage, or pipe, is formed through which the impounded water may escape, with disastrous results. It is natural that most of the papers dealt with the various precautions that have been taken to prevent such failures. Generally, the prevention of the removal of soil from beneath the dam has been achieved in one or other of three different ways, either by constructing a cut-off which would prevent the formation of springs or pipes in the subsoil and reduce the loss of water from the reservoir due to seepage; by covering, by means of a filter layer, the areas within which springs may develop, the layer being graded in such a manner that it would retain all solid soil particles without impeding the discharge of seepage water; or by tapping the flow of seepage water by a row of filter wells, thus preventing the formation of springs on the surface.

Twenty reports were submitted in the last group, dealing with experiences arising from the testing and actual use of special cements for large dams. Six of these reports dealt primarily with methods of testing cement for properties of importance for large dams, such as fineness of grinding, heat evolution and resistance to leaching by pure or slightly acidic waters, and with the properties of concrete such as extensibility and creep. A paper by F. M. Lea summarized British experience. An important paper by P. Håkanson (Sweden) dealt with the general principles for a standard specification of special cements for large dams. Nine other papers recorded experiences with the use of special cements in large dams, while the remaining four dealt with various subjects such as air-entraining agents, reactive aggregate, high alkali cement and expanding cement. The paper by R. F. Blanks and W. H. Price (U.S.A.) summarized the experience in that country with air-entraining agents in concrete. The purposeful entrainment of air in concrete improves its workability, reduces the water required for mixing, improves the durability and resistance to sulphate attack, and permits the use of less cement where strength is not a prime consideration, thus reducing heat generation. The permeability of the concrete is also not increased by air entrainment for the percentages commonly used. Air-entrained concrete is now being used in the construction and repair of large concrete dams in the United States.

On June 12 the delegates left Stockholm on two well-organised study tours which extended as far north as Harsprånget within the Arctic Circle, and terminated at Trollhättan in the south, on June 17. During the tours visits were paid to a number of power plants including those at Nämforsen, with a capacity of 45,000 kW., and completed in 1947; Forsmo, on the Angermanalven, of 70,000 kW. capacity, and nearing completion; Holleforsen, on the Indalsalven, of 120,000 kW. capacity, under construction; Harsprånget, on the River Lule 7 km. from Porjus, where the falls, constituting the largest source of water-power in Sweden, will be utilized in a power plant with an ultimate capacity of 260,000 kW.; Krangede, on the Indalsalven, built entirely in the natural rock and completed in 1936, with a capacity of 210,000 kW.; Stadforsen, also on the Indalsalven, constructed during the years 1936–40, with a capacity of 91,000 kW.; Hammarsforsen; and Vargon on the River Göta completed in 1934 with a capacity of 22,000 kW. A visit was also paid to the very interesting tunnelling operations in progress at the Hjälta plant. At Trollhättan the two power plants were visited, the Olidan plant on the Göta, the oldest State power plant in Sweden, constructed in 1910–20, and the Hojum plant, completed in 1943, with a capacity of 120,000 kW., which is constructed entirely in the natural rock formation. Both the Trollhättan stations are fed by the water from the Great Lake of Vänern.

Visits to several works were included, to the cellulose works belonging to Uddeholms A.B. at Skoghall, and to that of Svenka Rayon A.B. belonging to Kooperativa Forbundet near Älvenas; to the steelworks at Munfors Bruk belonging to Uddeholms A.B. and to the Karlstads Mekaniska Verkstad.

The opportunity was taken at Trollhättan, on June 17, of holding a meeting of the International Sub-Committee on Concrete for Large Dams, at which consideration was given to possible lines for future research. These included fundamental research into the physical structure of concrete, its elastic and plastic properties; the physical properties of concrete in large masses, such as extensibility and cracking, and means whereby the internal strain, temperature and humidity may be measured; the chemical interaction between cement and aggregates in concrete, particularly alkali reaction; surface treatment of concrete for dams and particularly by the application of vacuum treatment, and by the use of absorptive formlining materials; the properties of pozzolanas and natural cements; the preparation of a code of permissible unit stresses for use in dam design, to include a discussion of the minimum economic cement content per unit volume which is necessary to prevent concrete deterioration; and to study factors of safety in relation to computed three-dimensional working stresses.

Throughout the meetings in Stockholm and the subsequent tours the delegates were afforded the most generous hospitality by their Swedish hosts. Particularly memorable occasions were the official banquet held at Stockholm in the Town Hall, and the dinner given by the State Power Board at the Stadshotellet, Trollhättan. NORMAN DAVEY

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, October 4

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. G. C. Baldwin: "The Work of a Divisional Engineer in Northern Rhodesia".

Society of Chemical Industry (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6.30 p.m.—Mr. H. Baines: "The Photographic Latent Image".

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. Wilfred Thesiger: "A New Arabian Journey".

Tuesday, October 5

Institute of Physics, Electronics Group (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Discussion on "Valves for Low-Noise Wide-Bandwidth Amplifiers" (to be opened by Mr. R. J. Ballantine and Dr. A. E. Widdowson).

Society of Chemical Industry, Fine Chemicals Group (at the Royal Institution, Albemarle Street, London, W.1), at 7 p.m.—Prof. J. H. Burn: "Fine Chemicals for Medical Use".

Wednesday, October 6

Institute of Fuel, North-Western Section (at the Engineers' Club, Albert Square, Manchester), at 2 p.m.—Mr. A. Ahlstrom and Mr. A. Ullman: "Low Value Heat Recovery".

Society of Public Analysts and other Analytical Chemists (at Gas Industry House, 1 Grosvenor Place, London, S.W.1), at 7 p.m.—Scientific Papers.

Royal Aeronautical Society (at the Chamber of Commerce, Birmingham), at 7.30 p.m.—Dr. E. W. Still: "Some Aspects of Power Plant Development".

Thursday, October 7

Mineralogical Society (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. T. Graeme N. Haldane: Inaugural Address as President.

British Psychological Society, Industrial Section (at the British Council, 3 Hanover Street, London, W.1), at 6.15 p.m.—Miss Anne G. Shaw: "Applications of Motion Study, Past and Present". (The original films of Frank B. Gilbreth and modern films of Motion Study will be shown.)

Royal Institute of Chemistry (at the South-East Essex Technical College, Longbridge Road, Dagenham), at 7 p.m.—Dr. N. Booth: "Careers for Chemists".

Textile Institute, Blackburn Branch (in the Textile Lecture Theatre, Municipal Technical College, Blackburn), at 7.15 p.m.—Mr. J. Foster Beaver: "Technical Training for Industry".

Chadwick Public Lecture (in the Reception Room, the University, Bristol), at 8.30 p.m.—Mr. Asa Briggs: "The Public Health Act of 1948, a Forgotten Centenary".*

Friday, October 8

Oil and Colour Chemists' Association, Manchester Section (at the Engineers' Club, Albert Square, Manchester), at 2 p.m.—Dr. H. Plimmer: "The Reaction of Maleic Anhydride with Non-conjugated Unsaturated Fatty Esters".

Institute for the Study of Animal Behaviour (at the Linnean Society of London, Burlington House, Piccadilly, London, W.1), at 3 p.m.—Rev. A. E. Armstrong: "Social and Sexual Stimulation amongst Birds".

Physical Society (in the Lecture Theatre of the Science Museum, Exhibition Road, London, S.W.7), at 3.30 p.m.—Prof. R. W. Wood, For.Mem.R.S. (Johns Hopkins University): "Spontaneous Deformation of Crystals"; at 5 p.m.—Prof. S. Tolansky: "Current Investigations with Multiple-Beam Interferometry" (Charles Vernon Boys Address).

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Manchester Statistical Society, Industrial Group (at the Society of Architects, 16 St. Mary's Parsonage, Manchester), at 6.45 p.m.—Informal Discussion on "Quality Control in Great Britain and the U.S.A.".

Saturday, October 9

Institution of Chemical Engineers, North-Western Branch (at the College of Technology, Manchester), at 3 p.m.—Mr. W. S. Norman: "Fluid Friction, Heat and Mass Transfer in Turbulent Flow".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Head of the Department of Physics and Mathematics, Acton Technical College, Acton—The Chief Education Officer (F/GM), Middlesex Education Committee, 10 Great George Street, London, S.W.1 (October 9).

Research Officer in the Soils Chemistry Section of the C.S.I.R. Division of Soils, Adelaide—The Chief Scientific Liaison Officer, Australian Scientific Research Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 1938 (October 23).

Assistant Chemist at the Divisional Laboratory, Manchester—The Divisional Establishment Officer, National Coal Board, North-Western Division, 47 Peter Street, Manchester 2 (October 23).

Research Officer in the C.S.I.R. Division of Aeronautics, Fishermen's Bend, Melbourne—The Chief Scientific Liaison Officer, Australian Scientific Research Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 1633 (October 23).

University Post-graduate Fellowship in the Department of Anaesthesia, and an Assistant Lectureship in the Department of Physiology—The Registrar, The University, Liverpool (October 30).

Senior Lecturer in Biology in Victoria University College, Wellington, New Zealand—The Secretary, Universities Bureau of the British Empire, 32 Woburn Square, London, W.C.2 (Wellington, November 30).

Agricultural Chemist for research work on soil and other problems; an Entomologist who should be capable of identifying and advising on plant diseases; and a Plant Breeder to conduct crop improvement work, mainly on wheat; in connexion with a scheme of agricultural development in Northern Rhodesia—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Laboratory Assistant-Steward (male) for Zoology—The Head, Department of Biology, Chelsea Polytechnic, Manresa Road, London, S.W.3.

Senior Lecturer in Pharmaceutical Chemistry—The Dean, School of Pharmacy, 17 Bloomsbury Square, London, W.C.1.

ASPECTS OF COLONIAL DEVELOPMENT

THE fifth report from the Select Committee on Estimates for the Session 1947–48 (London: H.M. Stationery Office), with its forthright comments on Colonial development, makes its appearance at an appropriate moment. It is based in part on the observations of some of its members as a result of a visit to West Africa, and it has some relevance to the report, published later, of the commission of inquiry into the disturbances and underlying causes of these disturbances in the Gold Coast during February and March of this year. The recommendations and conclusions are equally of interest in relation to the recent report on "Colonial Research 1947–48". They emphasize the value and importance of the work being done by the Colonial Research Council, which has now replaced the Colonial Research Committee, and by the Colonial Products Research Council, the Colonial Social Science Research Council and the committees responsible for medical research, insecticide research, agricultural, animal health and forestry research, as well as the urgent need for the Colonial Economic Research Committee to function effectively.

In all these reports, two factors stand out as determining the successful issue of Colonial welfare and development: the problem of education and that of scientific man-power. Once again it is made manifest that shortage of qualified workers handicaps the work of the Social Science Research Council, of the Medical Research Committee and of the Insecticides Committee, and both the latter Committees realize how closely the effective utilization of results of their work depends on securing the co-operation of the native peoples.

Colonial research cannot, in fact, be pursued without regard to the question of native education, even of literacy at the lowest level. One passage in the Gold Coast report drives this lesson emphatically home. The economy of the Gold Coast rests on its four hundred million cocoa trees. Of them, one tree in eight is now affected by the virus disease known as swollen shoot, and if the disease is unchecked it is estimated that the cocoa industry will have disappeared in twenty years. The Government has accepted the opinion of its advisers that the way to check this incurable disease is by cutting down the diseased trees. Violent popular feeling and resistance to this destruction was aroused, because it was believed to be inspired by malign political motives; and the cutting out of the diseased trees has been stopped.

That passage in the report is pregnant with meaning for the whole future of Colonial welfare and development. While misrepresentation can create this kind of distrust, no mere adjustment of constitution or administration can restore the health of the body politic. The whole economy is put in jeopardy, and it is beyond the power of science or of Government to raise the standards of living of the native peoples, or even to avert a catastrophic fall. The problem of literacy, the programme of mass education, and the restoration or fostering of confidence beyond the power of the agitator to disrupt, must be the first tasks; and until they are undertaken there is no hope that the man of science can make the contribution to native welfare of which he has become increasingly conscious since Lord Hailey published his "African Survey" ten years ago.

Nevertheless, although the first task is to promote understanding, even at this stage the man of science has a contribution to make, as was made abundantly clear on several occasions during the recent meeting at Brighton of the British Association. This point is well brought out by Dr. E. W. Smith in the Frazer Lecture in Social Anthropology before the University of Liverpool delivered in October 1946, and recently brought up to date and published (London: Lutterworth Press, 1948. 3*s.* 6*d.* net). Events have well attested the soundness of the four factors upon which Dr. Smith suggested that the success of projects under the Colonial Development and Welfare Act depends: a sufficient supply of competent men and women to operate the plans; the goodwill and effective co-operation of the native peoples themselves; the wise planning and execution of the schemes by men and women who understand the native environment and the working of the native mind; and the co-operation of the economist, the agriculturist, the medical man, the psychologist, the nutritionist, the educationist and administrator, as well as others in the team-work required to devise and execute detailed schemes for each district. Dr. Smith is arguing above all for the anthropologist to make his vital contribution to the understanding of the native mind, and for the Government to make increasing use of such men in the task of government. His plea for social science to be used as an instrument of social engineering, and for more social scientists for the Colonial Service, is supported by the important section of the Gold Coast report already noted.

That Dr. Smith does not stand alone in his views was indicated in an address given by Sir Harold Hartley in Johannesburg in August at a conference of scientific and technical societies. Sir Harold, after urging a great extension of surveys of the material and human resources, limitations and needs of the relatively undeveloped parts of the world, reviewed the main factors likely to limit world economic advance, and the part of scientific workers in overcoming them. In spite of the huge increases in agricultural output which are potentially possible on the basis of existing knowledge, he said, man is still the limiting factor in peaceful advance. The same conclusion might well be drawn from the fifth report of the Select Committee on Estimates, although it concentrates attention rather on human limitations on the administrative side.

The Select Committee recognizes clearly that co-operation in development involves the association with the planning, of such organised opinion as may exist, of a carefully worked out policy of technical and vocational training related to the needs of a developing country for skilled man-power at all levels, and communal development or 'mass education' to induce the bulk of the population to take an active interest in their own welfare. It considers that the Nigerian Development Plan suffered from the beginning in that too little attention was paid to the need for associating African opinion with the various committees established to deal with it. This has now been to some extent righted, although African representation on the Central Development Committee is still inadequate.

So far as the felling of the diseased cocoa trees was a factor in the Gold Coast riots, it has been suggested that the Government failed to secure that its reasons were fully understood by native opinion, although improper methods of execution were also alleged. To engage the active co-operation of the native people themselves is not always easy, and may indeed involve questions of constitution as well as of administrative method. Communal development is still experimental; and on the information side, as the Select Committee notes, there is need for research into the kind of film appropriate to undeveloped peoples. Support from development funds of a scheme of research for ascertaining the reactions of African audiences is recommended. Similarly, it expresses its approval of the active pursuit of a comprehensive policy for the development of broadcasting throughout the British Empire, and urges that the closest informal contact should be maintained between the Colonial Office Information Department and the British Council in foreign countries.

This question of confidence and information has a bearing also on the part which private enterprise has to play in Colonial development. It is the declared policy of the Colonial Office to encourage private enterprise; but private enterprise cannot play its proper part in development so long as the belief exists among the Colonial peoples that it is unfairly exploiting them; nor, it might be added, while private enterprise elsewhere continues to be condemned by Government spokesmen. The Select Committee refers to local feeling against the United Africa Company in particular, but there is some hope for a settlement which will remove the two main grounds for such feeling.

The matter is not entirely divorced from that of the public development corporation. It is the responsibility of Government to prevent an undue proportion of the trade and industry of any particular Colonial area from becoming dominated by any trading organisation or group, and the Select Committee points out that in spite of the formal assurances of the Overseas Resources Development Act of 1947, it will be necessary to secure that such bodies as the Colonial Development Corporation and the Overseas Food Corporation do in practice respect the interests of the local Colonial people. The obvious danger is that of well-meant authoritarianism. Experience with the Cameroons Development Corporation indicates that special attention must be given to the relationship between such corporations and the local administrative authority.

The problem is in fact essentially one of administration—of securing that justice is not merely done but also seen to be done. The Select Committee makes no specific recommendations here; but the survey it recommends of the overall requirements of the Colonies for capital equipment for Government schemes, public corporations and private enterprise, should by eliminating some causes of friction make a distinct contribution here, as well as in the immediate objective of facilitating real planning in place of the agglomeration of departmental suggestions masquerading as the Nigerian Ten-Year Development Plan, on which the Select Committee makes the caustic comment: "This is not planning". Such a survey is the counterpart of the early investigation also recommended into the additional financial provision likely to be required to complete existing development schemes, and into the need for extending the ten-year period originally contemplated.

By and large, it may well be true that the administrative mistakes which the Select Committee criticizes are in part due to the overburdening of senior officers in the Colonial Service, and the Committee's observations on the shortage of staff should be noted. The Secretary of State for the Colonies stated in the House of Commons on July 8 that, during the last two and a half years, 3,300 men and women had been recruited for the Colonial Service, and on the administrative side the intake of the last two years was equal to that of eleven normal years. Excellent reports had been received on the quality of these recruits, and Mr. Creech Jones paid a warm tribute to the co-operation of the Universities of Oxford, Cambridge, London and elsewhere in training these recruits.

Nevertheless, the Select Committee reports that in May 1948 there were 1,185 vacancies in the Colonial Service, the greatest demand (315) being for men with engineering and architectural qualifications, while 168 administrators, 136 medical men and 110 agriculturists are still required. Apart from the strain on existing staff, it is imperative that immediate steps should be taken to overtake present shortage if Colonial development is to proceed smoothly. The shortage is equivalent to about three years ordinary intake, and has to be viewed in relation to the demand for trained man-power and woman-power as a whole, just as the Select Committee insists capital requirements of the Colonies must be reviewed.

That view presumably will be taken to some extent by the Advisory Council on Scientific Policy as suggested in its first annual report; but in the meantime the Select Committee makes several suggestions to secure the fullest use of available technical and scientific staff without lowering standards of qualifications. The limited number of fully qualified technicians available should concentrate on training staff for technical positions, and schemes should be adopted for recruiting into the forestry, agricultural and veterinary services men without academic qualifications but of good personal qualities and natural aptitude, and which would provide for academic training at a later stage when the pressure on the schools of forestry should have decreased. The requirement of university training as a qualification for recruitment might also be waived, and the temporary seconding of staff from Home to Colonial Service should be exploited to the utmost. Attractive schemes for seconding should be made for all technical services, providing appropriate guarantees in regard to promotion on return to Great Britain, and short-term contracts should be used to the fullest extent to obtain for the Colonies the services of scientific men and technicians with the highest qualifications, and development funds should be used for this purpose.

The Select Committee's recommendations here as well as in regard to salary scales and the provision of refresher courses are in line with those of the Barlow Committee for scientific staff generally. Clearly, to secure the most effective and best balanced distribution of scientific and other trained man-power between Britain and the Colonies involves encouraging mobility to the greatest possible extent, quite apart from the very favourable reactions such interchange has on scientific work itself. In all this the fullest possible encouragement must be given, and the greatest possible use made, of Colonial men and women themselves. Such association at all levels in the Colonial Service must prove a powerful factor in securing the understanding and co-operation of the Colonial peoples in development of their territories, nor should the influence of greater attention to the needs of Colonial students in Great Britain, both in regard to amenities or information, be overlooked.

Mr. Creech Jones' speech in the House of Commons on July 8 shows that the trend of the Select Committee's observations is fully appreciated. He stressed three points in regard to economic policy: the essential requirement of understanding and co-operation from the Colonial peoples themselves, to whom it must be made clear that the development plans are primarily concerned with the improvement of their trade and economic status and with the strengthening of the economies of their territories; the necessity for a sound economic basis for Colonial welfare; and growth of regional co-operation in this field with the French, Belgian and Portuguese Governments. During the past year a series of technical conferences has already taken place and more are planned on problems of technical development, communications, health, etc. The Government has also entered into discussions with the French and other associated Governments on the possibilities of further co-operation in regard to development schemes.

In spite of all this promise of genuine international co-operation in tackling problems of Colonial development in such areas as West and Central Africa, there is one seriously disturbing factor. That is the failure of the Trusteeship Council to reach the standard of constructive criticism set by its predecessor, the Mandates Commission of the League of Nations. The Select Committee's report demonstrates the weaknesses of British planning of Colonial development, and is a challenge to more constructive thinking and realistic planning in the light of inherent limitations of resources of materials and men and women. It is equally a rebuke to the irresponsible criticism and political polemics, with their disregard of the facts and conditions in the trusteeship of Colonial territories which has marred the proceedings of the Trusteeship Council, and is making it a disturbing factor rather than one which promotes the goodwill and understanding upon which Colonial development and welfare depend. Great Britain is faithfully meeting its obligations under the charter of the United Nations Organisation in regard to the provision of statistical and other technical information on economic, social and educational conditions, and the Colonial Office has done well to make the position plain in its recent Memorandum on Information on Non-Self-Governing Territories (London: H.M. Stationery Office, 1948. Colonial No. 228. 1*s*. net).

International co-operation could do something to diminish the present difficulties in Colonial development, particularly in the attack on technical problems, and in such matters as transport. No doubt the help of independent international men of science would be valuable in overcoming prejudices such as those which hamper the eradication of the swollen shoot disease of the cocoa tree. But such collaboration is only possible in an atmosphere of goodwill, and where there is manifest the willingness to make impartial investigation and the comparative study of different Colonial systems which characterized the work of the permanent Mandates Commission of the League of Nations.

CHEMICAL STIMULI AND INSECT BEHAVIOUR

Chemical Insect Attractants and Repellents

By Prof. Vincent G. Dethier. Pp. xv + 289. (London: H. K. Lewis and Co., Ltd., 1947.) 25*s*. net.

INSECTS live in a world of tastes and odours. To understand their reactions to the varied chemical factors in their environment would be a long step towards comprehending their ecology and would provide a firm basis on which to build certain methods of control. It is around these theoretical and practical considerations that Prof. Dethier has written his book on the action of chemical attractants and repellents in the life of insects. Unfortunately, exact knowledge in this field is very limited, and the contributions of the applied entomologist are copious but wholly empirical. None the less, this book should serve a useful purpose in bringing together in one volume what is known of the role of chemical attractants in the feeding, sexual and egg-laying behaviour of insects.

The botany and chemistry of the essential oils of plants and the relation of these substances to the choice of food-plants is reviewed—from the classic work of Verschaffelt on the predilection of Pierid larvæ for plants containing mustard oils to the recent detailed work of the author himself on the feeding habits of *Papilio* species in relation to the essential oils of Umbelliferæ and other plants. The chemistry of fermentation and the products of decomposition of protein and fat are considered alongside the extensive empirical literature on the production of attractants for the codling moth, fruit flies, blowflies and other insects. It is no fault of the author that this subject consists chiefly of lists of facts with few guiding principles. There is a valuable chapter in which the varied types of olfactometers and venturi type flow-meters are described, together with the methods of controlling the molecular concentration of odorous substances and determining the thresholds of response. On the practical side, the use of attractants in devising traps—for sampling populations and timing the application of insecticides or for actually reducing populations—is described in detail; and the whole subject of insect repellents is reviewed.

At the beginning of the Second World War the standard mosquito repellent was still oil of citronella; but commercial firms in the United States had evolved three synthetic repellents: dimethyl phthalate, 2-ethyl-hexane-diol 1,3 (Rutgers 612) and αα-dimethyl-α-carbobutoxydihydro-γ-pyrone (indalone). At great expense, large teams of American workers during the War tested thousands of additional substances; but the only practical outcome was the recommendation to use a mixture of the three named chemicals in the proportion of 6 : 2 : 2. No advances were made in the general knowledge of repellents. Indeed, the most valuable contribution in this field during the war years was the paper by Christophers[1], working almost single-handed; a paper which appeared too late for inclusion in Prof. Dethier's book.

The writing of this book was completed while the author was serving with the Armed Forces overseas. It has not been possible, therefore, for him to include certain recent ideas which go far to clarify thought on some of the fundamental questions involved. It has been pointed out by J. S. Kennedy that repellency is not a reaction but a change in distribution; and this altered distribution may be brought about in a variety of ways. For example, the author states categorically that D.D.T. possesses "no repellent qualities whatsoever". But slight D.D.T. poisoning causes excitation, and this in turn leads to such a change in distribution that insects are, in fact, strikingly repelled from buildings treated with D.D.T. Similarly the author ascribes the change of host plant by aphides at different seasons to physiological changes in the insect resulting in altered taste preferences. But it is becoming increasingly clear that the nutritional value of the host plant, as determined by the physiological condition of its foliage, may play a part at least as great as do specific flavours in inducing feeding and multiplication and so the building up of aphid populations.

V. B. WIGGLESWORTH

[1] *J. Hyg.*, **45**, 176 (1947).

PROCESS CHEMISTRY FOR THE CHEMIST

Chemical Process Principles

By Prof. Olaf A. Hougen and Prof. Kenneth M. Watson. Part 2: Thermodynamics. Pp. xv + 437–804 + xvii–xlviii. 30*s*. net. Part 3: Kinetics and Catalysis. Pp. xv + 805 - 1107 + xvii - xlviii. 27*s*. net. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1947.)

THESE volumes consider process problems of a physico-chemical nature and they do not contain any detailed discussion of equipment, of selection of materials for construction or of mechanical design. As the majority of chemical engineers in Great Britain first graduate in chemistry and only later specialize in their chosen subject, this approach should be of particular interest to them.

The treatment rests heavily upon recent American development as is shown by the number of references to American literature, which comprise 90 per cent of the total.

Part 2 opens with the consideration of the second law and quickly proceeds to the discussion of entropy and thermodynamic relationships. Modern methods are used throughout, as is exemplified by the inclusion of Shaw's method for making thermodynamic transformations.

Subsequent chapters consider the application of fundamental principles to problems in the compression and expansion of fluids, power generation and refrigeration. The treatment is developed for solutions and mixtures of various types by introducing the chemical potential, fugacity and activity concepts. This approach leads naturally to a study of vapour-liquid equilibria and to the fitting of experimental data to expressions such as the Van Laar equation. A chapter treats chemical equilibria and contains B. F. Dodge's useful discussion of the feasibility of a chemical reaction. The concluding section may be quoted as an example of the bold use which is made of fairly advanced recent methods for the solution of practical problems. These forty-seven pages deal with the calculation of thermodynamic properties from molecular structure by the method of group contributions and also by the more refined statistical methods.

Part 3 treats the subject of the kinetics of industrial reactions, which has rarely been considered elsewhere, and is thus in contrast with Part 2, where the development is along the lines that American thermodynamics has been following for many years. Encouraged by the recent advances in the theory of absolute reaction-rates the authors have applied the conceptions to the study of homogeneous, heterogeneous and catalytic systems of industrial importance. Particular attention is given to the interpretation of pilot-plant data. Economic considerations are emphasized and problems are included in the establishment of the optimum conditions of operation.

In this volume also the emphasis is on American publications. Frequent references are made to the International Critical Tables for experimental data and not to the original works.

Reactions are studied in terms of the general mechanism and in this way surface reactions are considered from the viewpoint of adsorption and dissociation, but there is no discussion of types of catalyst.

Calculations drawn from rather limited fields are often treated in considerable detail, for example, the work on codimer. The study of catalytic reactions culminates in the section on catalytic reactor design, where the authors state, "It is seldom practicable or possible to develop complete data prior to the design of plant, and the engineer is forced to improvise and extrapolate fragmentary data to conditions far outside the range of his past experience. It is in such cases that sound fundamental principles are of the greatest value in breaking down the available information into component effects and contributions of such simplicity that their individual trends can be estimated with fair assurance".

Homogeneous reactions in flow systems and also uncatalysed heterogeneous reactions such as the nitration of benzene, the combustion of coke, water softening and gas absorption are studied from this aspect.

In America during the recent War there were many examples of the scaling up of processes from the laboratory bench to large-scale production without using plant of an intermediate size. Volume 3 is valuable in indicating how this important subject can be tackled.

Numerous problems are set in both parts. The binding of the books is pleasing, and the quality of the paper is good by modern standards.

E. F. G. HERINGTON

MECHANISM OF NUCLEAR PHYSICS COUNTERS

Electron and Nuclear Counters

Theory and Use. By Prof. Serge A. Korff. Fourth printing. Pp. xi + 212. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1948.) 18*s*. net.

ELECTRICAL methods of counting the products of atomic disintegration have become widely used in many fields in recent years, and are no longer a tool for the specialist in nuclear physics alone. The Geiger-Müller counter for β- and γ-rays in particular has found increasing application in connexion with the 'tracer' technique. A monograph on this subject is therefore particularly welcome, especially as other works on this subject are by now out of date.

The present book is intended for the users of counters as well as the nuclear physics specialist, and the amount of fundamental physical knowledge assumed is not unduly large. Some acquaintance with the processes of ionization, recombination, etc., is assumed; but this should not deter the non-physicist from perusing the book. The author is an acknowledged expert in research on the mechanism of the Geiger-Müller counter, and, as one would expect, the volume contains a full and detailed account of the processes taking place in such a counter. The behaviour of proportional counters and integrating ionization chambers are also described reasonably fully, but the reviewer feels that the section on ionization chambers for counting is rather brief. The 'gridded' ionization chamber, now often employed when the measurement of the size of the ionization pulse is important, receives no mention, nor does the use of very pure inert gases to give 'fast' chambers in which the formation of negative ions is negligible.

While we would recommend perusal of this book to persons whose only contact with Geiger counters is as a user, it must be admitted that it is not a complete guide to counting technique. Such important matters as statistical errors in counting and the design of experiments to obtain maximum accuracy in a minimum time, for example, are much less fully treated than is the mechanism of the discharge. This book will not enable the non-physicist to dispense with specialist assistance in matters such as calculating the correction for absorption of particles in the counter window. It must also be admitted that the section on electronic circuits is only indicative of the type of circuits which can be used; design of circuits requires a deeper knowledge of circuit theory than can be given in a volume of this size. A few modern techniques, such as circuits for the recording of delayed coincidences with variable delay-time, receive no mention, and the reviewer has detected a few definite mistakes in the circuit diagrams. In a few places throughout the book, too, the derivation of the formulæ used is not completely clear, and another minor criticism is the use, without definition, of the term 'pre-dissociation'; in view of the importance attached to this process in self-quenching Geiger counters, we feel the term should have been explained.

It is recognized that it is difficult to produce a satisfactory book in a field in which research is still active, and in particular in a field where, as in Geiger counters, much past work has been of the empirical, 'cook-book' variety. Within the compass of the present volume, and granted its emphasis on the internal mechanism, it would be difficult to suggest any important improvements. The need for such a book is undoubted, and this one will be of use to the specialist and the general user of counters alike.

C. H. WESTCOTT

ON UNDERSTANDING SCIENCE

On Understanding Science

An Historical Approach. By James B. Conant. (The Terry Lectures.) Pp. xv + 146. (London: Oxford University Press, 1947.) 10*s*. 6*d*. net.

IN this book the President of Harvard University addresses himself to the problem of preparing suitable university courses (whether for graduates or undergraduates is not clear) for the purpose of producing an understanding of science in those whose future work is not to be scientific. He gives reasons why he thinks this important. By "understanding science" Dr. Conant means the acquiring of the special point of view which the successful investigator in a field of experimental science naturally attains, and he considers that this end can be achieved better by the presentation of selected 'case-histories' of particular advances in science than by a philosophical analysis of science as a whole. As illustrations of such case-histories he chooses the investigations of the pressure and elasticity of air in the seventeenth century, the discovery of the galvanic battery, and the development and overthrow of the phlogiston theory. These are outlined, with frequent comments on appropriate digressions which the teacher might make to emphasize salient points.

The definition of science which is implied in these considerations is that "as a first approximation, we may say that science emerges from the other progressive activities of man to the extent that new concepts arise from experiments and observations, and the new concepts in turn lead to further experiments and observations"; and among the most important of the characteristics of scientific investigation that are to be brought out are the influence of new techniques of experimentation and their connexion with the practical arts, the evolution of new concepts from experiment, the difficulties of experimentation and the significance of the controlled experiment, and the development of science as an organised social activity. Dr. Conant does not make the common modern error of transforming the fact that science *has* a social function into the illusion that science *is* a social function, and he is careful to distinguish the history of science from the history of technology; it is the former alone with which he is concerned. The book includes very useful bibliographies relating to the chosen case histories.

Taken as a whole, the book is both important and timely. The examples are admirably chosen and presented. It is claimed that the effort proposed would be a pioneer one, and so far as the United States is concerned (it is evident from various passages that this limitation is in Dr. Conant's mind) this may very well be so, although in Britain something similar has been in operation for some time. Perhaps experience of the working of the scheme might have led Dr. Conant to reconsider his contrast between the historical and philosophical approaches to the understanding of science. These can be made to supplement one another, and there is reason to hold that a course in the philosophy of science based on its whole history will lead to a better understanding of science than the mere recapitulation of selected past events alone, and will correct the error, almost inevitable when science is presented by means of special cases, of confusing casual with intrinsic characteristics. For example, such a course would suggest that the continuously progressive element in science is the growth of the field of correlated observations, and not, as Dr. Conant suggests, "changing concepts and evolving conceptual schemes". Newtonian mechanical science progressed enormously for more than two hundred years with scarcely any changing concepts and evolving conceptual schemes. Again it might help to elucidate the difficulty which arises when Dr. Conant emphasizes the (questionable) "differences in method between the observational sciences . . . on the one hand, and the experimental sciences . . . on the other", but draws all his case histories from the latter.

Such points, however, though important, are of secondary importance. It is much to be hoped that Dr. Conant's book will be widely read and will bear fruit.

HERBERT DINGLE

DESTRUCTION AND REHABILITATION OF AN ISLAND FAUNA

The Fauna of Krakatau, 1883–1933

By K. W. Dammerman. (Verhandelingen der Koninklijke Nederlandsche Akademie van Wetenschappen, Afd. Natuurkunde, Sectie 2, Deel 14.) Pp. xii + 594 + 11 plates. (Amsterdam: N. V. Noord-Hollandsche Uitgevers Mij., 1948.) n.p.

PRIOR to 1883 there existed in the Sunda Straits between Sumatra and Java three small islands, the largest of which, Krakatau, was composed of three active volcanoes, Perboewatan, Danan and Rakata. From May 20 until August 28, 1883, a series of volcanic eruptions succeeded one another until with a final and stupendous explosion the two volcanoes, Danan (400 m.) and Perboewatan, disappeared entirely, and Rakata (800 m.) was split right through the middle, one half of it together with the other two volcanoes sinking into the depths of the ocean, while a cavity 270 m. deep was made in the sea-bed. The main island was originally 9 km. long by 5 km. in breadth with a surface area of 33 sq. km., of which 22 sq. km. sank beneath the sea. Thirty-six thousand people in Java and Sumatra were killed by the resulting sea wave.

In October 1883 Verbeck visited the area and reported that the three islands were completely bare and covered with a hundred feet thick layer of ash and pumice which had exterminated the flora and fauna. The ground was still hot, and scalding steam issued from crevices.

The total destruction of the fauna and flora of Krakatau offered an excellent opportunity for studying re-colonization. Unfortunately very little was known of the previous fauna and, still worse, biologists failed to take advantage of the opportunity presented until too late. Cotteau landed on May 27, 1884, and found that the only sign of animal life was a minute spider; but in 1889 Selenka, who visited the island, found to his astonishment a rich fauna of insects and even giant lizards.

Dr. K. W. Dammerman now presents us with a comprehensive analysis of the work done on this problem of the re-colonization of Krakatau. He has himself made frequent collecting visits to the island, and has for many years specialized on the subject. In the first part of the book the fauna of the island is compared with that of surrounding islands. The re-colonization of other desert areas such as the Katmai volcano in Alaska and the volcano of Jorullo in Mexico is compared with that of Krakatau. The succession of biocœnoses, the sequence of animal categories in the islands and methods of dispersal are all studied in turn. The derivation of the fauna is also discussed. Part 2 (taxonomic part) consists of the complete annotated list, arranged systematically, of the animals now found on the Krakatau islands. Some of these are illustrated by text figures. The same list is repeated in tabular form without annotations to show at a glance the distribution of each species in the various islands in 1908, 1921 and 1933 respectively. The book concludes with an extensive bibliography and excellent photographic plates.

THE CANINE CULT

Dogs in Britain

A Description of all Native Breeds and most Foreign Breeds in Britain. By Clifford L. B. Hubbard. Pp. xii + 471 + 8 plates. (London: Macmillan and Co., Ltd., 1948.) 21*s*. net.

GREAT BRITAIN, per head of population, contains more dogs in private ownership than any other country in the world. Dog-breeding in Britain is a big industry, dog-showing a bigger, dog-owning a passion. Yet there is a profound ignorance about dogs, about everything to do with dogs, in Britain. Too many people own dogs because it is 'the right thing' to do, and not because they either love them or understand them: too many people breed freaks because it pays to do so. It is, in fact, not far from the truth to say that we are a nation of dog-owners and not, as we like to make out, a nation of dog-lovers.

How near to the truth that statement is can be seen from a study of canine literature. There is a small but excellent specialist Press; there are a number of specialist booklets devoted to individual breeds: there is one encyclopædic volume at a high price, a price beyond the reach of most dog-owners: there is a vast assortment of illustrated literature of a popular and definitely sentimental type; and it has always been the same. There is, therefore, a great opportunity for an all-round book about dogs; one that does not sentimentalize; one whose illustrations do not portray the dog as something rather more than human, stressing its 'fetching' ways to the exclusion of all else; one that both entertains and instructs. Mr. Hubbard has seized the opportunity. His book, most reasonably priced, will meet a long-felt want.

This book is uniform with those two excellent volumes by L. J. F. Brimble, "Flowers in Britain" and "Trees in Britain", which means that it is lavishly illustrated in colour and half-tone, yet in rather less than five hundred pages the author has managed to cover almost every aspect of the modern dog-world. Origins, breeding, training, management, breeds and varieties, diseases and ailments, all are treated authoritatively but simply. Mr. Hubbard never becomes involved, never ceases to be anything but practical, never ceases to entertain. He has, too, the wide view. He is not content to deal only with the popular British breeds, but also gives details of many foreign breeds, few specimens of which are to be seen here, but which in their own countries are as popular as the cocker spaniel is in the English suburbs.

On the practical side—on breeding, training, management, and on the health and care of the dog—what he has to say, and the way in which he says it, is beyond praise. His chapter on the dog in literature and art (in which he had the assistance of Mr. Stuart Tresilian, who was also responsible for the beautiful coloured plates, and Mr. Stuart Raye) cannot fail to appeal to anyone with a fondness for dogs. All those who have at any time "given their heart to a dog to tear" will read this section again and again.

Mr. Hubbard will not, however, find universal acceptance for all his views on the origin of the dog, or for all he has to say on the very interesting (but surely, more complicated) subject of the wild dogs of the world. In particular, it is certainly over-simplifying matters to dismiss the pariah dog as semi-wild, if, by that, is meant feral. Pariah is a word that has come to be loosely used in English. That there are feral dogs infesting the Middle and Far East is beyond question; but there is also a quite distinct form (some authorities recognize two types) of truly wild pariah. These are matters, however, for the specialist with zoological leanings, and do not affect in any way the great value of the book for the non-specialist dog-owner and -lover.

But on another matter, of great concern to all dog-owners and -lovers, Mr. Hubbard has allowed his enthusiasm to run away with him. He speaks of dog specialists as "cynologists". He even goes so far as to describe Dr. John Caius, the learned founder of Caius College, Cambridge, as "the Elizabethan cynologist", and, further, to put the generic separation of dog and fox to the credit of advance in "cynological study". It was due, of course, to nothing of the sort. But it is the word that is disturbing. It has no place in the dictionary, and it should have no place in the world of dogs, for if it is to be accepted what are we to call the specialists in horses, cats, pigs, and other domestic animals?

Enthusiasm is, however, a good fault. To read this beautifully illustrated and produced book is to catch much of the author's enthusiasm. It should have, and will thoroughly deserve, a great welcome from the dog world, for there is no one—specialist no less than novice—who will not be the better for reading it.

BRIAN VESEY-FITZGERALD

RESEARCH SERVICES IN EAST AFRICA*

By Dr. E. B. WORTHINGTON
Scientific Secretary, East Africa High Commission

A PROVISION of the Colonial Development and Welfare Act of 1945 was to earmark up to a million pounds a year for ten years from the British Treasury for research in and on behalf of the Colonial Empire, and in consequence there has been much activity both at home and overseas in designing systems which will enable these funds to be spent in the best way. The purpose of this article is not to recapitulate the work at the London end, centred on the Colonial Office, because this is summarized in the published annual reports of the Colonial Research Committee (now Council) and other advisory committees and councils concerned, and has already been noticed from time to time in *Nature*. The object is to describe how the new system is working out in a Colonial region, with the advice and assistance of the London authorities.

For this purpose East Africa is taken as the example for several reasons. It comprises three contiguous territories, Kenya, Tanganyika and Uganda, with the island Protectorate of Zanzibar adjoining, so that its components do not suffer from separation by wedges of territory administered by a foreign power, as in the case of the West African region. East Africa has advantages over its neighbouring region of Central Africa, because all its component territories are ultimately responsible to the British Parliament through the Secretary of State for the Colonies, whereas Central Africa has to combine two such territories, Northern Rhodesia and Nyasaland, with Southern Rhodesia which has Dominion status and is therefore responsible only to itself and does not qualify for grant aid under the Colonial Development and Welfare Act. A further reason for taking East Africa as the example is that, in addition to the territorial Governments, there has been since April 1948 a form of regional Government, the East Africa High Commission, which has its own 'Central Assembly' and secretariat, and is directly responsible for a number of scheduled services, among which inter-territorial research and other scientific activities take a prominent place. The East Africa High Commission has a scientific secretary whose duties are specially concerned with creating a framework within which science can be pursued with a reasonable degree of freedom in the main subjects involved.

Inter-territorial research in East Africa may be said to date from the Ormsby-Gore Commission of 1924, as the result of which the old German scientific station at Amani in Tanganyika was developed into an Agricultural Research Institute having functions in the whole region. Many other Commissions, notably the Hailey Survey of Africa during 1934–37, emphasized the need for more research and for closer co-operation in research. Nevertheless, until the War, investigations were arranged mainly on the basis of technical departments of territorial Governments, within which very few officers could be sufficiently freed from routine duties to undertake research in the true sense. In addition to Amani, however, one or two inter-territorial institutions had been established, notably the Central Veterinary Research Institute at Kabete in Kenya, and the Tsetse Fly Research Institute at Shinyanga, which, though primarily headquarters of the Tanganyika Tsetse Department, operated in the adjacent territories as well. During the War, isolation of research workers tended to become more acute; but latterly visits from a number of men eminent in particular scientific spheres have resulted in recommendations, most of which have now been bound into a general scientific framework. The stage is set, therefore, for a big improvement in research, designed to provide a more adequate background of knowledge on which to base development in East Africa.

I would be the last to claim that what we have planned will be sufficient for more than a few years to come. It is significant in this connexion to compare the research plan for East Africa with that of a neighbouring region comparable in size, namely, the Belgian Congo. In the group of subjects concerned with primary production from the soil, the Institut National pour l'Étude Agronomique du Congo Belge has an annual subvention towards recurrent expenditure of more than a hundred million francs, 3 per cent or so of the whole expenditure on public services in the country. In addition, the Belgian Government has established in 1948 the Institut des Recherches Scientifiques en Afrique Centrale for long-term research in other subjects, with a capital sum of 450 million francs. By comparison, the expenditure on research in East Africa, including grant aid from Colonial Development and Welfare funds, is not expected to reach even 1 per cent of total public expenditure during the next few years. This suggests a scientific deficiency in the British as compared with the Belgian Colonial system which must be made good in course of time.

In the scheme for East African research the first principle being applied is to separate research from executive responsibility wherever possible. Much of the research is being arranged, therefore, in a series of organisations with functions extending over the whole region; and these will be advisory to the executive technical departments, such as those concerned with agriculture, veterinary work, forestry, tsetse control, public works, which will remain responsible to the separate territorial Governments.

The advantages of pooling a good part of the research effort in this way will be several: first, greater efficiency, including savings on capital expenditure and personnel; secondly, better recruiting prospects, because inter-territorial research organisations will offer wider scope to young scientific workers; thirdly, easier arrangements for seconding specialists to and from centres of research in Great Britain and the Dominions; and fourthly, better service to the territorial Governments and those interested in using the results of research.

Five inter-territorial research organisations are being established now, concerned with the following subjects: agriculture and forestry; veterinary science and animal husbandry; tsetse flies and trypanosomiasis; fisheries; scientific and industrial research. These do not cover by any means the whole field. They are restricted to the main productive subjects, not because we attribute less weight to subjects of social importance, such as health, sociology and education, but because research on these is at present being arranged direct by the authorities at the Colonial Office, with the East Africa High Commission serving in the capacity of local agent rather than controlling authority. There are, however, several branches of research on social subjects of a long-range character attached to Makerere College in Uganda, which is tending to become the East African University.

---

* This article summarizes a fuller document on the subject which was laid on the table at the first meeting of the Central Assembly of the East Africa High Commission in April 1948.

It is not intended that every scientific man in East Africa will become part of an inter-territorial research organisation, because it will be necessary for each of the main executive departments, being part of the territorial Governments in each territory, to retain its own group of specialists for routine and advisory work. Whereas the research organisations are likely to initiate new lines of investigation, it is expected, moreover, that territorial departments will become intimately concerned as soon as a branch of research reaches the technological stage, when initial results require testing under a variety of practical field conditions.

The research organisations themselves will be responsible direct to the East Africa High Commission; but each will maintain close contacts on one hand with the territorial technical departments concerned, and on the other with the respective council or committee at the Colonial Office. Ultimately it will no doubt be necessary to have a hierarchy of councils and committees in East Africa, bringing a wide variety of experience to bear on the lines which research should follow. We are not starting with this, however, but are adopting the principle of not holding meetings unless there are important matters for discussion and decision. In practice, of course, many conferences and meetings have to be held, but the permanent system of advisory and executive bodies is being allowed to grow up naturally, following rather than preceding the initiation of actual research.

Certain principles apply to each of the five research organisations enumerated above, and to others which may be established. The concept of the 'Research Organisation' rather than the 'Research Institute' is important as implying that the work will pervade the whole of East Africa and not be concentrated in one building. In each case a headquarters of the organisation is being established at some convenient place, and some activities involving extensive facilities and costly apparatus will inevitably take place at headquarters. But the headquarters will be easy to get away from as well as to reach; and the object of each research organisation will be to conduct research on behalf of East Africa wherever it can be pursued most efficiently. This may be at a scientific centre in Great Britain or a Dominion, at the headquarters of the organisation in East Africa, at a territorial laboratory or out-station, or in a tent in the bush. Another important point is that our research organisations will be staffed by members of the new Colonial Research Service which is expected to be inaugurated in the near future. The terms of service will involve contributory pensions, so that staff will be transferable without difficulty to and from scientific centres elsewhere, particularly those which subscribe to the F.S.S.U.

Considering the five research organisations in more detail, their designation by initials seems inevitable, and in each case the subject is preceded by E.A. (East Africa) and followed by R.O. (Research Organisation). The largest is E.A.A.F.R.O. (Agriculture and Forestry), which is directed by Dr. B. A. Keen, and will have also Dr. H. H. Storey, who is returning to active research in Africa after valuable work as secretary for agricultural research at the Colonial Office. This organisation, which will absorb the existing staff and facilities at Amani, is intended to grow during five years to more than forty qualified men of science and a similar number of other European staff. Its main divisions will be concerned with soils, fertilizers, crops and pastures, pests and diseases, animal husbandry, sylviculture and forest products. A new headquarters is to be established at a convenient site in a healthy climate some fifteen miles from Nairobi, where a thousand acres of good land have been made available for the purpose by the Kenya Government. In addition, it is intended to have outstations distributed through East Africa, ultimately one in each main ecological zone, using where possible the existing agricultural and forestry experimental stations of the territorial departments. One section, concerned with taxonomic botany, will have special duties associated with the Royal Botanic Gardens at Kew in helping to prepare a much-needed Flora of East Africa, and the main herbarium will be established at the Coryndon Museum in Nairobi, where it will be easy for reference. For the initial capital expenditure on E.A.A.F.R.O., some £280,000 are being made available from Colonial Development and Welfare Research funds, and the aggregate recurrent expenditure for the first five years is estimated at £297,000, of which £165,000 is likewise to come from Colonial Development and Welfare Research funds, the balance being subscribed by the East African Governments.

Next in the list is E.A.V.R.O. (Veterinary), directed by Dr. E. G. White. In staff this will grow to about half the size of E.A.A.F.R.O. It is concerned with all aspects of animal disease, animal health and husbandry, and the production of biological products, which is already a service extending through a good part of the African continent and elsewhere. A part of E.A.V.R.O. concerned with disease is developing from the former Central Veterinary Research Institute and will continue to be located at Kabete, near Nairobi, where additional buildings are being erected. A new part, concerned with animal husbandry, will have headquarters side by side with those of E.A.A.F.R.O., seven miles from Kabete. Capital expenditure on this organisation is expected to be £125,000 provided from Colonial Development and Welfare Research funds, and recurrent expenditure for the first five years about £399,000, £94,000 coming from Colonial Development and Welfare Research funds, £80,000 from the East African Governments and the balance from the sale of biological products.

E.A.T.T.R.O. (Tsetse and Trypanosomiasis) is at present in two sections. Tsetse research is based at Shinyanga in Tanganyika, in charge of Mr. W. H. Potts, with a staff of ten scientific workers and a similar number of other Europeans; human trypanosomiasis research is some thirty-five miles away Tat inde in charge of Dr. H. Fairbairn, with three men of science. Expenditure for the next five years is estimated at £218,000, of which two-thirds is voted from Colonial Development and Welfare Research funds and the balance provided by the East African Governments. These two centres have been in existence for many years, and some reorganisation is expected, including the binding together of the tsetse and trypanosomiasis research with the separate department of Experimental Tsetse Reclamation, which is in charge of Mr. Napier Bax.

E.A.F.R.O. (Fisheries) is at present quite small, dealing only with research on lakes and rivers. Its director is Mr. R. S. A. Beauchamp, who will have four or five scientific workers on his staff, and the headquarters are at Jinja in Uganda, at the point where the Nile originates from Lake Victoria. Capital expenditure of £64,000 and recurrent expenditure for five years of £51,000 are provided in whole from Colonial Development and Welfare Research funds. It is hoped that a fisheries research unit will soon be added for the marine waters of East Africa, and there is also recently established in Kenya a small station on the slopes of Mt. Kenya for investigating the special problems of streams and trout fisheries.

E.A.S.I.R.O. (Scientific and Industrial) will, it is hoped, be one of the most important of the research organisations, its subjects including buildings, roads, secondary industries, food processing and water pollution. Only a part of it yet exists, the East Africa Industrial Research Laboratory, situated in Nairobi, in charge of Mr. H. B. Stent. This organisation is intended ultimately to form a kind of local counterpart of the Department of Scientific and Industrial Research in Great Britain. Clearly, it will not be able to undertake extensive researches of a fundamental character except in special cases which demand proximity to local conditions. Wherever possible, problems arising in East Africa would be passed on to larger centres of research such as those established in Britain by the Department of Scientific and Industrial Research.

There are many scientific subjects of importance to Colonial development which are not covered by these research organisations. To mention a few: meteorology is looked after by the East African Meteorological Department, which includes research in its purview wherever it can be fitted in with the regular activities of recording and disseminating information. Hydrology is another subject of basic importance, and the beginnings of its study on a regional basis exist in a newly established hydrological survey of the Nile Basin within East Africa, necessary in connexion with the project for converting Lake Victoria into the largest reservoir in the world. Geology is still a function of territorial departments which, however, are coming into closer line with each other, aided by annual conferences which have been inaugurated in 1948. The same applies to work on the fauna, for which again annual meetings between game wardens have been started. There is much research progressing on insecticides with particular reference to their use against tsetse flies, this being the responsibility of the Colonial Insecticides Committee in London, which maintains a research unit in East Africa and is initiating a series of trials with aircraft in 1948. The problem of locusts is another subject on which research in East Africa is part of a wider service, in this case international in character. Archæology, in which East Africa has outstanding wealth, still awaits more extensive and more permanent facilities. Finally, there is great need for research on economics and statistics, and the East African Statistical Office, which, like the research organisations, is responsible to the East Africa High Commission, is already in existence and likely to expand.

SCIENTIFIC ASPECTS OF COLONIAL DEVELOPMENT

THE president of the British Association for the Advancement of Science, Sir Henry Tizard, referred in his inaugural address at the Brighton meeting to "our bounden duty, and the only certain way of safeguarding our future so long as we remain a large food-importing country, to develop our Colonial territories, particularly the under-populated African colonies, where the increase in population that would follow the control of disease and the increase of food supply would open fresh markets for international trade". The president of Section E (Geography) of the Association, Lord Rennell of Rodd, speaking of "Geography as a Social Science, with special reference to Africa", said, "For our own good name, the social geographer must be called on to play his very large part in adapting our changing conceptions of African administration, and in seeking to rationalize the mess which western European nations, including we ourselves, have made in the African continent". His address was followed by a discussion in Section E on the scientific aspects of colonial development, to which a number of the younger geographers, several with experience of work and conditions in the Colonies, contributed. While recognizing that geography is only one of many sciences which could be, and must be, applied to the problems of the Colonies, the geographers were all agreed that their subject has a very definite and distinctive contribution, though one which has not hitherto been given adequate recognition by those in authority.

As to the nature of the contribution, there was considerable discussion. Some believed in the existence of a 'colonial geography', recognized, according to one speaker, by the governments and universities of all the Colonial Powers, except Great Britain, and particularly by France and the Netherlands: but a majority emphasized that colonial territories call for precisely the same type of geographical investigation as any other part of the world, and that the geographer's particular task is the study of the regional characteristics of different areas. Such a study requires the correlation of numerous branches of science, ranging from geology to social anthropology. One speaker recommended the formation of a single colonial institute, forming a part of one of the Universities of Oxford, Cambridge or London, which would not only be responsible for the training of administrative and technical officers for the Colonies but also would undertake, or be cognizant of, colonial research in most, if not all, branches of knowledge. In an institute of this type, the geographer, with his interest in widely different aspects of environment and society, would have an important role. Another speaker suggested that insufficient use is made at present of the very considerable geographical knowledge of officials and others who have lived for long periods in the Colonies.

Lord Rennell described geography as "both the science and the art which deals with mankind on the earth on which we live". It studies in particular the interaction of physical facts on one hand, and economic, social and political conditions on the other. The influence of physical environment upon human activity is generally most noticeable among more backward people—though even here there is no such thing as 'environmental control'; and it is, therefore, particularly appropriate that geographers should concern themselves with tropical regions. Increasingly it is being recognized that the economic development of the tropics cannot come about except by the conquest of disease, the raising of standards of living, and the institution of comprehensive programmes of drainage and irrigation, road-building and port development. The blind belief in the inherent fertility of the tropics has at long last disappeared: and projects like the groundnut scheme in East Africa can succeed only after the most careful study of the facts of geology and topography, temperature and rainfall, natural vegetation and soil types. These facts are rightly studied by specialists—by geologists, meteorologists, plant ecologists, soil scientists, and the like. Too often, though, the interactions of these facts are inadequately considered, since they lie in the province of no particular specialist: and it is here that the geographer believes that he has a place in the scientific hierarchy, since by the nature of his training he is specially equipped to look out for interconnexions. He is not content with the facts of either geology or meteorology or botany, taken by themselves, in any particular area. He wants the complete picture—made up of physical conditions and human responses—or, as he puts it, the 'regional geography'.

The work of many of the economic and other missions to British Colonies in recent years would have been greatly facilitated if less time could have been spent in fact-finding, and more attention paid to the elaboration of concrete development programmes. Had the regional geography of British Colonies been studied as fully as that of, say, France —or even as inadequately as that of Great Britain itself—these missions would have had at least a basis on which to build. As it is, the regional geography of the Colonial Empire remains unwritten, apart from the isolated work of pioneers such as Clement Gillman in Tanganyika Territory. In this connexion the new colonial universities and colleges have an important contribution to make to our geographical knowledge of the world.

More than one speaker stressed the need for a colonial atlas, in the preparation of which geographers would take a prominent role: such an atlas would include distribution as well as topographical maps. The French and Dutch colonial atlases were quoted as excellent examples, and reference made to the successful efforts of Section E of the British Association in pushing forward the preparation of a National Atlas for Great Britain. It was suggested that as a first stage, maps might be prepared for groups of British territories, full use being made of the technique of mapping from air photographs and of the resources of the Directorate of Colonial Surveys.

Lord Rennell concluded by stating that facilities are now available for geographers to an extent never known before, and that the Colonial Office has recently asked specifically for trained geographers for research investigations in the Colonies. It is now open to geographers to make as effective a contribution to the study of the problems of colonial development as they have made at home, through the Land Utilisation Survey and in other ways, to the problems of agriculture and of town and country planning. Their fellow-scientists will judge the validity of the geographers' claim by the quality of their work in the colonial field and by the distinctiveness of their contribution.

NATURE OF INCENTIVES

As might have been expected, the discussion of 'incentives' in the meeting at Brighton of Section J (Psychology) of the British Association afforded yet another opportunity for attempting to define the nature and extent of the responsibility of scientific workers for industrial efficiency. From various points of view, industry was challenged to try out new techniques and policies of management, and men of science were challenged to develop new concepts and procedures in the organisation of research.

Mr. Nigel Balchin, who opened the symposium, expanded his now well-known thesis that under present social conditions the traditional incentive of financial rewards has broken down, and that in future industry must rely upon entirely different motives for the maintenance of optimum effort. "If we have," he said, "on one hand a perfectly reasonable demand for a high material standard of life, which can only be supplied by productive effort, and on the other an equally reasonable demand for happiness in activity, the only possible solution is *to make work the happy activity*." Since we do not yet know how this is to be done, the first responsibility of the man of science is to engage in research into basic principles. Psychologists should stop 'trying to run other peoples factories' and concentrate on research into general principles.

The main themes of the second paper (that of the present writer) were in more than one way complementary to those of Mr. Balchin. There is, of course, much that we do not know; but, it was argued, there is also much that we know well enough but do not act upon. Research in this field, the results of which would be applicable, cannot be conducted entirely outside the factory but depends on close collaboration between scientific workers with more than a superficial knowledge of industrial administration and managers with more than a superficial knowledge of scientific method. One field in which such collaboration would be especially fruitful, both in the application of existing knowledge and in the promotion of fresh research, is that of 'target setting' both on a national scale and in the detailed procedures of time and method study. Evidence of the ripeness of this particular harvest could be adduced from recent trends of thought in scientifically minded exponents of time-study procedures and from the increasingly open-minded and experimental mood of industry itself in this regard. *Target*, the monthly bulletin of production publicity of the Central Office of Information, is full of reports of new incentive experiments, the results of which should be well worth scientific observation and assessment.

Following up a point first made by Mr. Alec Rodger in the conference at Leamington of the Division for the Social and International Relations of Science of the British Association, it was further suggested that among the preconditions of the effective application of existing technical knowledge is the application of existing knowledge of another kind—of principles governing human relations in industry, on which there is a surprising unanimity of opinion among moral philosophers, political reformers and religious teachers of every school, party and sect. For example, the often quoted precept of Immanuel Kant that "every man should be treated as an end and not merely as a means" is one that in principle admits of translation into scientific terms and into terms of industrial practice. So translated, it might be worth submitting to tests acceptable to the statistician and methodologist as theoretically sound, and acceptable to management as workable in practice.

An even more fundamental challenge to science and management would seem to have been implied by the argument of the third contributor to the symposium. According to Mr. Adam Curle, who approached the subject from the point of view of an anthropologist, the very existence of an incentives problem is symptomatic of a malady in modern society. In primitive societies necessary work is as automatic as eating or sex ; and our present problem is nothing less than that of recreating these conditions. This, of course, is not to be achieved by a mere regression to the original order. The need is for a new social order "in which the anxious tensions resulting in withdrawal and isolation from the group can be reduced". We need to provide the conditions of a 'psychological' as well as those of a constitutional democracy. Then the incentives problem would again disappear. Nothing very specific was suggested as to the way in which this might be done; but it would depend on close collaboration between social scientists of many different kinds. The results obtained in army resettlement units, it was suggested, gives some indication of the lines along which to work.

Mr. Alec Rodger, through what at first appeared to be an excursion into lexicography, raised an issue of the greatest moment. The term 'incentive', he pointed out, is commonly used by industrialists and defined in dictionaries by reference to incitements that are essentially passing rather than permanent in effect. On the other hand, the preceding speakers had appeared to be almost exclusively concerned with the conditions that continuously maintain an optimum level of effort throughout the working weeks and years. "Admittedly we need long-term programmes for the improvement of morale, for in the long run this is the only manner in which high industrial productivity is likely to be properly established and sustained ; but in our present plight we cannot disdain to use any device which shows promise of yielding quick results." An example of the sort of research which was needed was quoted from some studies of the Social Survey which had given indications that different types of motivation operate at different intelligence levels.

Speaking with intimate and first-hand experience, Mr. Rodger had things to say on the functions of the psychologist in relation to management and administration. The root of the problem, he suggested, lies in the fact that the technical adviser will often miss the opportunity both to understand the principles on which his colleagues work and of dealing with critical situations unless at the decisive moment he is prepared to do the job himself, since he can act with insight and confidence when they cannot.

The discussion as a whole, however inconclusive and however limited in suggestions likely to yield 'quick results' it may have seemed, served a useful purpose in revealing something of the total dimensions of the problem. There is clearly, and by general agreement, a need for expansion and intensification of research and development in which a due balance is preserved between the advance of knowledge and the application of what is already known. There is need for advances both in fundamental research and in the development of practical techniques. It is probably through the development of managerial techniques for using what is already known that the 'quick results' are most likely to be obtained. But it is here, more than anywhere else, that Mr. Rodger's distinction needs to be kept in mind. There is a widespread view among industrial psychologists that the benefits derived from temporary incitements are often paid for dearly through their subsequent effects in fatigue and reaction. If they be correct in this opinion, the use of such expedients can be defended only in an emergency the passing nature of which can be predicted with some assurance. Here, as elsewhere, the best results are likely to be achieved by those who combine a sense of the need for quick results with the wider and the longer view. Perhaps this combination is not to be found in any single scientific or managerial group ; and the need will only be met by the kinds of collaboration concerning which all the speakers were agreed. It is accordingly somewhat sobering to reflect that in spite of the widespread interest in the problem, the number of workers actually engaged in relevant research at this time is extremely small.

C. A. MACE

TRANSMISSION OF EFFECTS FROM THE ENDINGS OF NERVE FIBRES

A DISCUSSION on the transmission of effects from the ends of nerve fibres occupied an afternoon session of Section I (Physiology) of the British Association on September 9. Sir Henry Dale introduced the discussion by saying that we may agree on the assumption that the liberation of one or another chemical substance with a specific stimulating action is the means by which, in vertebrates, nerve impulses are transmitted from the endings of all efferent fibres of the peripheral nervous system, whether pre- or post-ganglionic fibres of the involuntary nerves, or motor fibres of the voluntary nerves. But there remains a wealth of problems still open to discussion concerning details of such a process.

Since two of the speakers were dealing with the extension of this theory to the vast complex of synaptic junctions in the central nervous system, Sir Henry Dale first discussed this problem. The exciting possibilities presented by studies in this field, he said, have acted as both a stimulus and a deterrent. When, more than twenty years ago, he told Sir Charles Sherrington, then already in retirement, about the evidence that had been obtained at that time in his laboratory for the transmitter function of acetylcholine at preganglionic and voluntary motor nerve endings, Sir Charles' immediate reaction was to insist that a process observed at peripheral synapses must furnish some kind of analogy for events at those of the central nervous system. Referring to the experimental attempt of Dr. W. Feldberg to distinguish central synapses at which transmission may be cholinergic from others at which it is not, Sir Henry Dale said that such a differentiation raises the question as to what the transmitter may be at these others. For it is difficult to suppose that synapses in the central nervous system can differ among themselves so fundamentally in function that transmission at some should be cholinergic and at others involve no kind of chemical agent. Referring to the experiments of Mr. J. W. S. Pringle and Mr. G. M. Hughes, by which the discussion is extended to the nerve ganglia of the ventral chain in an insect, he again pointed out that we should scarcely expect to find that the transmission across synaptic junctions in an insect's ganglion would involve a process fundamentally different in kind from that which is effective at vertebrate synapses.

Turning to the recent developments of evidence for the nature of the transmitter substances themselves in the peripheral vertebrate system, Sir Henry Dale discussed several outstanding and very acute problems in this field of research. For cholinergic transmission the released agent is acetylcholine itself, but there has never been the same certainty with regard to the transmitter of adrenergic fibres, adrenaline. "This problem has recently acquired a new aspect through the evidence produced by U. von Euler, that the sympathomimetic agent extractable from sympathetic nerves or from the spleen, appears, indeed, to be chiefly *nor*-adrenaline rather than adrenaline, and Gaddum's finding that the substance released in the spleen when its adrenergic nerve is stimulated is likewise, for the most part, the primary amine. One is tempted to speculate whether a renewed investigation of the suprarenal gland might not reveal *nor*-adrenaline as a constituent of its medulla as well as its long known N-methylated homologue, adrenaline." We should further keep in mind that the list of the transmitters, even at the peripheral cytoneural junctions, should not yet be regarded as finally restricted to the two concerned with the recognized cholinergic and adrenergic processes of transmission. Histamine may have to be considered as contributing, at least, to the so-called antidromic vasodilator effect, a possibility envisaged by Lewis and his co-workers and supported by evidence from Ungar and others.

The next problem taken up concerned the presence of the transmitter substances and the relevant enzymes for their synthesis and destruction along the whole course of a nerve fibre. According to Sir Henry Dale, it does not seem possible to accept the suggestion so vigorously urged in recent years by Dr. Nachmansohn and his associates. According to these speculations, acetylcholine would not only be responsible for the transmission from nerve ending to a secondary neuron or an effector cell, but also for the propagated nerve impulse along the nerve fibre. "Such a conception offers, of course, the kind of intellectual satisfaction which many minds obtain from a simplifying and co-ordinating generalization. There is, however, a remarkable lack of unequivocal evidence to support it directly, while the ingenuity of its supporters is sorely taxed to discover even plausible ways of escape from the facts which contradict it." Only some nerve fibres are cholinergic. The theory postulates a stimulating depolarizing action of acetylcholine on the nerve fibres. But as Lorenté de Nó has shown recently, the nerve fibre in continuity is as indifferent to acetylcholine-chloride, even in isotonic solution, as to cane sugar, provided only sufficient physostigmine, or other anti-cholinesterase, is added, to prevent the esterase in the nerve from hydrolysing the acetylcholine, and thus liberating acetic acid ions from it in a harmful concentration. We may, however, have to consider the possibility, put forward with all reserve by Sir Henry Dale, that the transmitter which we find distributed along the fibres represents a kind of reserve needed for the regular and immediate replenishment of the depots at the endings, and that the passage of impulses along the fibres to their endings would somehow facilitate a drift of the transmitter down them in the same direction.

The last problem dealt with by Sir Henry Dale concerned the presence or absence of the transmitter substances, not along the nerve fibres, but in the protoplasma or neurosoma of the nerve cells themselves from which the axons in question originate.

Prof. F. R. Miller, of the University of Western Ontario, then described his discovery of the central stimulating actions of acetylcholine and eserine, effects which are consistent with the suggestion, made so early as 1934 by Sir Henry Dale, that acetylcholine may be concerned in the transmission at central synapses. Even in the experiments with eserine, acetylcholine is probably the actual stimulating agent, because the central actions of eserine, like its peripheral ones, are also probably more or less fully accounted for by its power of inhibiting cholinesterase, the enzyme which destroys acetylcholine, thus leading to its accumulation at the synapses.

The technique adopted by Prof. Miller in these experiments consisted in soaking small pieces of filter paper in a solution of acetylcholine or eserine and applying them to the cerebral cortex of cats and rabbits. Eserine applied in this way to the centres for the fore- or hind-limbs evoked within a few seconds motor effects of rapidly increasing intensity in the corresponding limb of the opposite side. The cortical electrogram was modified. The normal large slow waves were replaced by small fast waves suggesting an asynchronous firing of cortical neurons. Acetylcholine similarly applied to a previously eserinized cortex induced large 10 per second spikes in the cortical electrogram, together with motor effects in the muscle units, as shown with the cathode ray oscillograph by Miller, Stavraky, Woonton, Wilkey and Luke. According to Miller, each 'acetylcholine spike' suggests a synchronous firing of a number of cortical neurons under the influence of "cells with short axons", each of which controls a number of pyramidal cells.

Particularly striking were more recent experiments in which Prof. Miller applied dilute solutions of acetylcholine, with the same technique, to the floor of the fourth ventricle. These experiments were performed on decerebrate cats which had received an injection of eserine. The local application of acetylcholine stimulated the inspiratory centre, and later on caused convulsive discharges from the hypoglossus nucleus, shown by powerful retractions of the tongue. These effects, like the comparable stimulating actions of acetylcholine on the spinal cord, described by Bülbring and Burn, were abolished by atropine.

Dr. W. Feldberg remarked that he approached the problem of central synaptic transmission by acetylcholine in a different way. Miss M. Vogt and he studied the synthesis of acetylcholine in various relatively small but well-defined areas of the brain and medulla. An analysis of the distribution of the enzyme system responsible for the synthesis of acetylcholine in the central nervous system led them to the conclusion that acetylcholine is not the universal central synaptic transmitter, and that often, although by no means always, the arrangement of neurons in the afferent and efferent nervous pathways is such that cholinergic and non-cholinergic neurons alternate with each other. For example, in the voluntary motor pathway, the finding of a high enzyme concentration in the anterior horns, the motor nuclei of the cranial nerves and the anterior roots suggests the cholinergic nature of the lower motor neuron. On the other hand, the low values encountered in the pyramidal tracts indicate that the upper motor neuron is not cholinergic. In the motor area of the cerebral cortex an intermediate value was found. This might suggest that cholinergic neurons converge on the pyramidal cells. Similarly, the low values found for the posterior roots and their central continuation, the funiculi gracilis and cuneatus, are in agreement with the conception that the first neuron of the afferent sensory pathway is non-cholinergic. However, the relatively high values obtained for the nuclear masses in which these sensory fibres end might be evidence for the cholinergic nature of the second neuron in the sensory pathway.

The third neuron, originating in the thalamus and leading to the cortex, is probably non-cholinergic, as suggested by the low values found for the fibres in the posterior parts of the internal capsule, which at least in man is said to contain the thalamic radiation. Another example was provided by the optic pathway. The retina contains large amounts of the enzyme which synthesizes acetylcholine, whereas the optic nerve is practically free from it. This suggests that acetylcholine is the chemical transmitter at one or more of the synaptic junctions in the retina. Among these junctions may be that to the ganglionic layer from which the non-cholinergic optic nerve originates. The optic fibres end mainly in the lateral geniculate body, and the high enzyme values found for this region may indicate a cholinergic nature of the third neuron in this pathway. Dr. Feldberg stressed the fact that, however attractive such a pattern of a succession of alternating non-cholinergic and cholinergic neurons may be, it would be dangerous to have a conception which is too simplified and diagrammatic. We must realize that if there are two different kinds of neurons in the central nervous system, then on purely statistical grounds there should be a great incidence of such an alternation.

The great number of problems involved in the process of central synaptic transmission and their complexity were brought to light by beautiful experiments on cockroaches reported by Mr. J. W. S. Pringle and Mr. G. M. Hughes. They had passed weak polarizing currents laterally through the metathoracic ganglion of the cockroach. This affected the flexor-extensor balance in such a way that the leg on the negative side flexed while that on the positive side extended. With longitudinal stimulation, ascending currents flexed the legs on both sides of the cockroach and descending currents encouraged extension. It is interesting that Skoglund had observed similar reaction patterns in corresponding experiments on cats. Mr. Pringle and Mr. Hughes suggest that the weak polarizing current excites internuncial fibres and not the motoneurons, because preparations in which only a single nerve was left attached to the ganglion did not show this differential effect when the polarizing current was applied between ganglion and nerve. In these preparations the negative electrode on the ganglion excited, and the positive inhibited, any resting discharge in the larger motor fibres, irrespective of whether the nerve supplied flexor or extensor muscles.

Concerning the problem of chemical transmission, they pointed out that the evidence available shows that the motor nerves to the muscles are not cholinergic in the Arthropoda. On the other hand, acetylcholine may well have a transmitter function at the central ganglionic synapses, because its application to these ganglia causes a discharge of impulses in the motor nerve fibres. It is further possible that the differential effect of polarizing current is due to the fact that in Arthropoda, as in other organisms, two types of transmitter substances are involved in central synaptic transmission.

At the end of the meeting, Prof. R. J. S. McDowall showed a few slides from his recent experiments on the rat's diaphragm preparation, in which he had obtained a curare-like block of neuromuscular transmission as an effect of lack of glucose.

OBITUARIES

Dr. William Cullen

By the death, at the age of eighty-one, of Dr. William Cullen, a prominent figure and a vivid personality has been lost to a wide circle of men actively engaged in the varied pursuits which are related directly and indirectly to chemical technology, to metalliferous mining and to metallurgy.

It would be difficult to enumerate the manifold activities with which his name has been identified over the past fifty years; but these are happily recorded, for the most part, in the numerous papers and addresses which he had contributed to the various scientific and technical bodies with which he was associated. His earlier work was published under the auspices of the Chemical, Metallurgical and Mining Society of South Africa, of which he became president in 1905. In later years, the *Transactions of the Institution of Mining and Metallurgy, the Institution of Chemical Engineers* and *the Society of Chemical Industry* have been enriched by his contributions. By each of these bodies in turn he was elected to the presidential chair.

Dr. Cullen's life-work can be divided into two periods. The first was that of his earlier work in South Africa, commencing with his appointment, in the later stages of the 1899–1902 War, as general works manager, at Modderfontein, of the British South African Explosives Co. While retaining his close association with South African affairs to the end, particularly in regard to educational matters, the second period of his career dates from the time of his return to Great Britain in 1915, when, in association with the late K. B. Quinan and W. McNab, he was entrusted by Lord Moulton (then directing the Department of Explosives Supply) with the design and lay-out of new explosives factories called for by the exigencies of the First World War.

A Scotsman, reared in the hard school of the west coast and the Clydeside, Cullen received his early training in Glasgow, successively at Hutcheson's Grammar School and at what was then the Andersonian College (now the Royal Technical College). As a chemist, he became a member of the staff of Nobel's and later of Kynochs. It was this early experience of the chemistry of explosives that fitted him for the very prominent part he was destined to play in the vast developments which occurred in the mining industry in South Africa following the termination of the War of 1899–1902. The necessity had already been recognized and to some extent met, for the independence from outside supplies of industrial explosives, and it fell to Cullen's lot to promote this independence in step with the growing and pressing demands.

In these surroundings Cullen found scope for his wider interests and inherent sympathies. The admirable spirit of co-operation, and the refreshing freedom from secrecy regarding experience and knowledge of technical matters, which he found to exist among those directing the mining industry were fully in accord with an outlook which may be regarded as one of his happiest characteristics. Two matters in particular caused him grave concern. First, the appalling mortality, at that time, among those engaged in underground mining, and secondly, the widespread neglect to provide technical training for the younger members of the community. To both these problems Cullen gave unremitting thought and attention, which persisted, in one form or another, to the end of his life.

As the direct outcome of his own responsibilities, Cullen sought for more precise information regarding the nature of the gases resulting from the explosives which, at that time, were in general use underground. The previous neglect of this aspect of blasting operations was attributed by Cullen to a lack of contact between the manufacturers and the users of explosives, but "there," he said in one of his addresses, "we lived next door to each other." The results of the investigations, with relatively crude appliances and despite the serious hazards which close sampling involved, shocked them all. Ready, as he always was, to face up to unpalatable facts, he pursued these investigations in collaboration with his colleagues, T. Donaldson, E. Weiskopf and W. Waters. Discussions, following the publication of their results, lasted many months. Public conscience was aroused, and the Government took note. A commission was appointed (at which Cullen was an important witness) and the matter was followed by further work.

Although these inquiries did not attempt to go to the root causes of silicosis, as subsequent work has done, they, nevertheless, did much towards eliminating the hazards of poisoning from carbon monoxide and the oxides of nitrogen by establishing on a firm basis the need of an 'oxygen balance' in regard to all explosives used underground. Cognizance of this important requirement was taken all over the world. At the same time, Cullen was not unmindful of the unsolved problems of ventilation in mines; and the stimulus thus given to the need for greater attention to this matter has helped towards the immense advances which have now been made in this direction.

In regard to education and training, both in South Africa and in Great Britain, Cullen lived to see many of his cherished hopes and aspirations realized. As a member of the original Transvaal Council of Education and as an active participant in the work of the Transvaal Technical Institute, he helped to pave the way for the foundation of the University of the Witwatersrand. Recognition of these services was made in 1925, when the University conferred upon him the honorary degree of LL.D. He continued to represent the interests of the University in Great Britain. Of many ways in which he sought to promote its welfare, perhaps the outstanding service was the part he played, under the chairmanship of the Earl of Athlone, in making good, so far as possible, the losses sustained by the Library of the University as the result of the disastrous fire on Christmas Eve of 1931.

In addition to his unremitting services on the councils of those institutions and technical bodies over which he had in turn presided and of which he was later elected to honorary membership, he was an indefatigable lecturer and speaker on matters which came within his wide experience. As recently as 1944 he was called upon to preside over the deliberations of the Science Masters' Association.

Such were the activities of a man of far-seeing vision and buoyant disposition with a unique experience of men and affairs, one who has left a mark on generations of chemical technologists, mining engineers and metallurgists, and one to whom they could look with confidence at all times for guidance, encouragement and enduring friendship.

S. W. SMITH

Sir Thomas Crozier

MAJOR SIR THOMAS HENRY CROZIER, formerly His Majesty's Chief Inspector of Explosives at the Home Office, died at Folkestone on September 26 at the age of eighty. Born at Monkstown, County Dublin, on February 26, 1868, he was educated at the United Services College, Westward Ho, and the Royal Military Academy, Woolwich, and was gazetted to the Royal Artillery in 1888. He held the posts of chief instructor in ammunition and explosives at the Ordnance College and afterwards chief instructor in artillery at the Royal Military Academy. He retired from the Army on April 17, 1908, when he was appointed one of His Majesty's inspectors of explosives at the Home Office.

On October 5, 1914, he rejoined the Army and served in "A" Battery of the 58th Brigade, Royal Field Artillery, 11th Division, Mediterranean Expeditionary Force. He was eventually invalided, and on recovery and after urgent representations by the Home Office owing to the greatly increased pressure of work, he rejoined the Explosives Department of the Home Office in October 1915. On February 12, 1926, he was appointed His Majesty's chief inspector of explosives. His work was rewarded on June 3, 1930, by the conferment of a knighthood. He retired on March 30, 1931.

During Sir Thomas's term of office in the Explosives Department, low-freezing explosives were introduced into general use in Great Britain, and the Petroleum Act, 1926, and the Petroleum (Consolidation) Act, 1928, were passed. Regulations were made for the conveyance by road of petroleum spirit, carbon disulphide and for the 'permanent' gases compressed in a metal cylinder. He was associated with a number of committees dealing with petroleum, dissolved acetylene, fire extinguishers, permitted explosives, classification of explosives used by the Fighting Services, carriage of dangerous goods in ships, welded containers, and cylinders for permanent and liquefiable gases. During the years 1927 and 1928, in conjunction with the late Prof. J. S. S. Brame, he carried out, on behalf of the Minister of Transport, a public inquiry into the modifications of the petroleum spirit by-laws proposed to be made by the Port of London Authority.

During the Second World War, the work of the Explosives Department increased considerably and, in consequence, Sir Thomas Crozier was asked to rejoin the Department, which he did on June 1, 1940. He relinquished this temporary appointment on September 30, 1944, owing to ill-health.

NEWS and VIEWS

Prof. F. E. Fritsch, F.R.S.

After forty-one years as head of his Department, Prof. F. E. Fritsch retired from the chair of botany, Queen Mary College, London, on September 30, in his seventieth year. Though scarcely expected in boyhood to live to twenty, his already long and remarkable career has been an arduous one, its keynote continuous application sustained by a powerful sense of the absolute value of knowledge and work. In 1905, during his first appointment as assistant professor (1902–10) at University College, London, he obtained his D.Sc. (London), started a year's additional work at Birkbeck College and completed with Boodle the well-known translation of Solereder's "Systematic Anatomy". In 1907, when Queen Mary College (then East London College) was first recognized as a school of the University of London, he was appointed to take sole charge of the newly initiated Botany Department, becoming in 1910 its full-time professor with one assistant. His eight years collaboration with Salisbury from 1912 onwards resulted in the five familiar and ubiquitous joint text-books, and were shortly followed by his appointment to the University chair. His large and continuous output of contributions to algal and other botanical literature, even including the re-writing of West's "British Freshwater Algæ" which appeared revised in 1927 and the production of his largest work, "The Structure and Reproduction of the Algæ" (2 volumes, 1935 and 1945), though testifying to his unremitting industry, betray only a fraction of the activities he found possible concurrently with routine work and the steady development of his Department, which were rewarded in 1932 by election as a fellow of the Royal Society. He took an active share in the foundation in that year of the British Freshwater Biological Station at Wray Castle, on the Council of which he has acted as chairman ever since. His gift for diplomatic organisation and management has rendered him invaluable on numerous committees, including the Library, Scholarships and Central Research Fund Committees of the University of London.

To Prof. Fritsch himself this milestone of retirement will make comparatively little difference. Mentally vigorous as ever and still looking forward, he will continue to act on all these Committees in London, and by the courtesy of Prof. F. T. Brooks and his successor, Prof. G. E. Briggs, he is being enabled to continue his algal work in highly congenial surroundings at the Botany School, Cambridge. His friendly personality, equable disposition and philosophic outlook have ever made him an entirely congenial colleague. With his retirement Queen Mary College loses its longest servant, and the whole staff will miss the cheerful presence of an esteemed personal friend.

Wave-lengths for Broadcasting

Following the meeting held by the International Telecommunications Union in Atlantic City in 1947 (see *Nature*, May 29, 1948, p. 863), a series of subsidiary conferences is being held in various parts of the world to deal with the allocation of radio wave-lengths for various purposes. According to *The Times*, a three-months conference in Copenhagen has just reached agreement on a new plan for the distribution of the long and medium wave-bands for European broadcasting stations. The new convention, which has been signed by twenty-five countries, will come into effect in March 1950, and will mean that many of the B.B.C.'s transmitters will have to change their operating frequencies. The allocation of short waves for sound broadcasting purposes will be decided by a conference which is to meet at Mexico City on October 22.

The last effective plan for the allocation of broadcasting wave-lengths to the European countries was made at Lucerne in 1933 (see *Nature*, December 2, 1933, p. 848, and January 20, 1934, p. 94); since then, the claims of some countries, particularly those which were less technically advanced at that time, have greatly increased. But the number of wave-length channels available has not increased, and so agreement on a new allocation has only been possible by some nations accepting less than their full requirements. The Lucerne plan gave the United Kingdom one long and ten medium wave-lengths; but in order to carry on its services, the B.B.C. has taken into use another long and two additional medium wave-lengths, which had been allocated to other countries. The new Copenhagen plan gives the United Kingdom one long and thirteen medium wave-lengths, and in some cases increased power may be used. These are considered to be sufficient for the B.B.C. programmes to be carried on substantially as they are at present.

German Scientific Text-books

Dr. Julian Huxley writes: "Students of biological evolution will, I think, be interested to hear something about the new book by Dr. Bernhard Rensch, 'Neure Probleme der Abstammungslehre', published by Ferdinand Enke Verlag, Stuttgart, 1947, which I have recently received and read. It appears to me to be a most valuable work, which treats of the method, and especially the course, of evolution, in a comprehensive way. Its most original feature is the number of tables it contains, giving quantitative expression to various rules of evolution. It is also interesting in that the author, though working in complete isolation during the War, has arrived at conclusions in general similar to those reached by American and British specialists in the subject during the same period.

"It may be also useful to set forth the methods by which this, and other German books, may now be obtained. Anyone wishing to purchase books published in Germany may do so by placing his order through any bookseller, who may then apply directly to the publisher in Germany. The transaction is administered through the Joint Export and Import Agency of Military Government and payment can be made in the currency of the country in which the original order is placed. The delay in obtaining the book may be a matter of some weeks, or, of course, considerably longer if the publisher has not previously obtained a licence for export from the Joint Export and Import Agency. However, many publishers who foresee a demand outside Germany for a particular book will have obtained the required licence soon after the appearance of the book in Germany."

Chemical Names, Formulæ and Ciphers

The system of notation of organic chemical compounds described by Dr. G. M. Dyson has quickly been followed by a second, and those who missed the original lecture in Birmingham last October will now be able to study at leisure what Messrs. Gordon, Kendall and Davison describe as a universal notation covering inorganic and organic chemistry and the chemistry of ions, free radicals and transition complexes ("Chemical Ciphering." Pp. 46. London: Royal Institute of Chemistry. 4s. net). The claims are thus even larger than those of Dr. Dyson, and a logical proof of the validity of the ciphering is appended, given the definition of a chemical species as a set of atoms individually stated, in which given pairs of these atoms are linked together by directed bonds and the net charge of the set, and of any discrete ions contained in it, are specified. The authors claim, moreover, that the system is expressed in the language of "basic chemistry", and in accord with modern trends in the theory of molecular structure. Whether the system can be mastered by a chemist in about an hour, as they also claim, is at least doubtful; and if they under-estimate the intellectual effort required to comprehend and apply their system, they have probably also under-estimated the willingness of chemists as a body to make such an effort.

That factor has to be weighed against whatever advantages a cipher notation can offer. The crucial question is the reality of those advantages. Is there, for example, any real hope that mechanical methods, such as punched cards, will be sufficiently widely used to justify the considerable financial investment involved. If universal use is probable, what are the real advantages of an entirely new cipher notation over some extension of the Richter - Stelzner formula system, for such purposes? So far as systematics are concerned, what in economic terms are the advantages gained by a new system over the thoroughgoing application, for example, of the International Rules? A large part of the confusion and ambiguity in organic chemical nomenclature is due to the failure to apply those rules systematically and universally, and the very conservatism which has prevented such a relatively simple reform does not encourage optimism about the universal acceptance of systems involving so much larger an intellectual effort as well as a break with past practice.

Nigerian Livestock Mission

The Secretary of State has sent a mission to visit West Africa to investigate the livestock industry in Nigeria and the Cameroons under British mandate, with particular reference to meat production. The Mission will also engage in discussion where necessary with the authorities of the neighbouring French territories on problems of mutual interest. The leader of the mission will be Sir Frank Ware, formerly animal husbandry commissioner to the Government of India, and the members will be Mr. Thomas Shaw, a director of Messrs. Zwanenberg-Organon, Ltd., and Mr. Gilbert Colville, who has special experience in the breeding-up of African cattle. Arrangements are being made for local officers of the veterinary, agricultural and geological departments to be attached to the mission. The mission will probably pay a further visit to West Africa in February or March to see the country and the cattle at the end of the dry season. During its first visit, the mission is spending a few days in the Gold Coast to discuss problems in connexion with the cattle industry there.

Irrationality of the General Cubic Threefold

Reference has already been made in these columns (*Nature*, March 31, 1945, p. 385) to the proof by Prof. G. Fano, formerly of Turin, of a long-conjectured and important result in algebraic geometry. It has been known for nearly a century that the plane curve with equation $f_3(x, y) = 0$, where f_3 denotes a cubic polynomial, is in general irrational, that is, its points cannot be set in one-to-one algebraic correspondence with the points of a line; in fact, its co-ordinates are expressible as elliptic functions of a single parameter. In contrast to this the general cubic surface, given by an equation $f_3(x, y, z) = 0$, is rational, and the method of representing the surface biunivocally on a plane was obtained so long ago as 1866. It was thus natural to inquire whether the general cubic threefold, given by an equation $f_3(x, y, z, t) = 0$, is rational or not; the question posed by the Italian geometers some sixty years back long resisted all attempts at solution, and hence became one of the celebrated problems of geometry. In 1942, Fano (then in his seventieth year) at last established its irrationality; from Switzerland, where he was living as an exile, he communicated the discovery to the Pontifical Academy of Sciences, and this, after various delays, has now been published with cognate researches ("Commentationes", **11**, 635; 1947). Fano's proof, though conceptually simple, involves considerable detail, and, in fact, marks the conclusion to a long chain of investigations, dating from 1907, when Fano showed that the general quartic threefold $f_4(x, y, z, t) = 0$ is irrational. It is interesting to note that the entire programme of the research was foreshadowed in a communication made to the International Mathematical Congress held at Bologna in 1928; this has now been carried out in all its details.

The Little Ringed Plover in London

In 1947 little ringed plovers (*Charadrius dubius curonicus*) bred in the London area for the fourth year in succession, and there was a remarkable increase in numbers (*British Birds*, **41**, No. 2; February, 1948). Eight nests were found, and four other broods seen. Because of the possibility that at least two pairs changed their sites after disturbance the exact number present is unknown; but there were certainly eleven and possibly fourteen pairs. Although the majority of the birds were again in Middlesex, there was an extension of range to three other counties and first breeding records were obtained for Essex (four pairs), Kent and Berkshire (one pair each). It is probable that the apparent sudden increase from four pairs in 1946 to a minimum of eleven pairs in 1947 is in part due to a lack of observation in previous years. It is curious that the known breeding range in Britain is, so far, restricted to Tring (where it bred in 1938 and 1944) and the London area (where it has bred annually since 1944). This may simply be due to lack of observation in other suitable places.

Turkish Technical Review

The first issue (dated August 1948) has appeared of the *Turkish Technical Review* (*Teknik Dergi*), a monthly periodical which is claimed to be the first independent journal of that character published in Turkey apart from those coming from State institutions. It consists of forty-eight pages of text, with introductory notes by the Turkish Minister of Transport, by Prof. Tevfik Taylan, president of the Technical University of Istanbul, and the editors. There is an article on modern military tanks, another on jet motors and gas turbines, a description (translation) of a lathe with electronic control, an article (translation) on the application of plastics in chemical apparatus and a section on textiles. In addition, there are the usual notes, abstracts of technical papers, reviews of books, notes on patents, etc., and the first page of a technical dictionary (English–Turkish–French–German). In each issue of the journal the contents page is to appear in the same four languages, and translations of any particular article will be prepared on request. The address of the new journal is: *Teknik Dergi*, Divanyolu Caddesi No. 16/3, Sultanahmet, Istanbul.

British Museum (Natural History)

THE galleries of fossil reptiles, fishes and plants in the Geological Department of the British Museum (Natural History) will be re-opened to the public on October 11. Most of the skeletons of the larger fossil animals had been dismantled and packed away in 1939, while others which could not be moved suffered damage during the War. The re-assembling and repair of all these specimens is still in progress; but the work is now sufficiently advanced to permit visitors to see once more the dinosaurs, the plesiosaurs and the ichthyosaurs. In the fossil fish gallery there is a series of dioramas of the fish-life of various geological periods from the Devonian onwards, and in Gallery VII there is a special exhibit illustrating the early history of palæontology. The rearrangement of the fossil plant gallery is not yet complete, but the student will find an adequate series of specimens exemplifying the plant life of the past.

Lighting Exhibition at the Science Museum

MANY of the exhibits in the "Darkness into Daylight" Exhibition at the Science Museum, London, which closed on October 6, were contributed by the Electric Lamp Manufacturers' Association; these have now been handed over to the Museum for incorporation in the permanent collection on illumination which is being re-modelled. The objects range from six dioramas illustrating the development of domestic lighting from medieval to modern times to a complete historical survey of the development of the fluorescent lamp. In addition, there is a working model illustrating stage lighting, many experimental and newly introduced types of lamp and several interesting demonstrations. The new illumination section of the Science Museum is being built in three sections. In the first, historical portion, the aim is to give a picture of the sequence in which lighting developed from prehistoric to modern times by a series of well-lit exhibits interspersed with a series of dioramas. The second section, most of which is in existence, illustrates by means of push-button demonstrations the principles upon which good illumination depends. The final section will be devoted to modern developments in discharge tubes and fluorescence. It is hoped to open the new section to the public early next year.

Navigation through the Ages

THE Institute of Navigation (c/o Royal Geographical Society, 1 Kensington Gore, London, S.W.7) is organising, with the Royal Geographical Society, an exhibition of "Navigation through the Ages", to be held during December 17–January 20. The exhibition will be opened by the Duke of Edinburgh, and in connexion with it there will be three meetings of the Institute: "Radio and Position", by Sir Robert Watson-Watt (December 17); "The Navigator's Story", by Prof. E. G. R. Taylor and Prof. W. M. Smart (December 20); three films on radio systems, with a commentary by R. F. Hansford (January 10).

University of London: Appointments

THE following appointments in the University of London have been announced: Prof. L. Dudley Stamp, professor of geography at the London School of Economics and Political Science since 1945, to the University chair of social geography tenable at the School; Mr. J. V. Dacie, to the University readership in hæmatology tenable at the Postgraduate Medical School of London; Dr. C. L. Foster, to the University readership in biology tenable at St. Mary's Hospital Medical School.

Irish Chemical Association

AT the annual general meeting of the Irish Chemical Association, held in Dublin on September 22, the following officers and Council for the 1948–49 session were elected: *President*, Prof. T. S. Wheeler; *Vice-President*, D. Crowley; *Hon. Secretary*, G. F. O'Sullivan; *Hon. Treasurer*, J. G. Belton; *Council*, Dr. V. C. Barry, Dr. T. G. Brady, Prof. W. Cocker, Prof. T. Dillon, W. V. Griffiths, Miss M. MacNeill, N. V. Nowlan and F. T. Riley. Prof. Wheeler will deliver his presidential address, "The Training of a Chemist", in the Department of Chemistry, Trinity College, Dublin, at 7.45 p.m. on October 20.

Announcements

DR. RICHARD E. SHOPE, of the Rockefeller Institute for Medical Research, has been appointed associate director of the Merck Institute for Therapeutic Research. Dr. Shope is an authority in the field of experimental medicine and is known for his work on the virus of swine influenza. To provide Dr. Shope with special facilities for the study of animal pathology, a new building is being constructed in Rahway, N.J., by the Merck Institute.

DR. W. C. PRICE has been appointed to the University readership in experimental physics tenable at King's College, London, as from January 1, 1949. In 1937 Dr. Price became demonstrator in physical chemistry at the University of Cambridge, and during the War he worked at the Royal Aircraft Establishment, Farnborough, and for the Ministry of Supply and Ministry of Aircraft Production. Since 1943 he has been senior spectroscopist at the I.C.I. Physical Chemistry Research Laboratory, during which time he spent a session at the University of Chicago as research associate.

THE third commemoration day lecture at the Imperial College of Science and Technology will be delivered by Prof. Herbert Dingle on October 25. The title of Prof. Dingle's lecture will be "Some Reflexions on the History of Science".

MR. LEONARD CUNDALL, senior geography master at the Henry Thornton School, London, has been appointed a lecturer in the Department of Education of the International Wool Secretariat. He will lecture on wool to schools and adult educational bodies in the north of England and Scotland. Mr. Cundall, who graduated at the University of Leeds, has been chairman of the Secondary Schools' Standing Committee of the Geographical Association and of the Committee of the Assistant Masters' Association, which produced the "Memorandum on the Teaching of Geography" including the development of the wool industry in the West Riding.

Two New British Minerals

A WHITE mineral coating joint-faces in quarries in the Northampton Ironstone (Inferior Oolite) was long ago recorded as allophane. During the six-inch geological survey of that ironstone field during 1939–44 comparable material was widely recognized, and this note is published with the concurrence of the Director of the Geological Survey and Museum.

Exceptional developments were observed at the Lodge Pit of the Irchester Ironstone Co., two miles south of Wellingborough. Here the white material is present in its usual form as a wall coating associated with limonite and gypsum; but there are also widened joints or fissures up to one foot across occupied by white mineral enclosing fragments of oxidized ironstone. The white matrix of this fissure breccia includes compact, white mineral with a conchoidal fracture and a white plastic clay-like mineral.

Preliminary optical examination by Dr. J. Phemister had suggested the presence of more than one mineral, and it was noteworthy that the plastic material rapidly loses water in air and crumbles to a white powder which on wetting does not regain its plastic character. The air-dried material is fine-grained, anisotropic, with a mean refractive index close to 1·510.

X-ray examination reveals two predominant powder patterns, one corresponding to the fully hydrated mineral with longest spacing 12·9 A.; and a second pattern, easily distinguished from the first, with a longest spacing of 9·2 A. The pattern of the fully hydrated mineral was obtained free from that of the air-dried mineral by X-ray examination of a wet sample which had been kept in contact with water and sealed in a lithium-glass capillary. A few specimens yielded the X-ray halo pattern characteristic of allophane (hydrated aluminium silicate), and halloysite was also identified.

The silica percentages recorded by Mr. C. O. Harvey in the following partial analyses, made in the Geological Survey Chemical Laboratory, of two air-dried samples (Nos. 1 and 2) probably correspond to admixture of up to 5 per cent of allophane.

Chemical analyses of the new basic aluminium sulphate, basaluminite

	1	2	Composition for calc. $2Al_2O_3.SO_3.10H_2O$
	%	%	%
SiO_2	2·4	3·6	—
SO_3	15·6	14·2	17·2
Al_2O_3	43·0	41·3	44·0
Fe_2O_3	0·3	0·2	—
P_2O_5	tr.	1·0	—
Water (by difference)	38·7	39·7	38·8

The composition of the air-dried material is close to that of the mineral felsobanyite; but powder photographs of specimens of the latter in the British Museum collections are quite different from those of the Irchester minerals. It is suggested that the air-dried mineral should be called basaluminite to distinguish it from aluminite $Al_2O_3.SO_3.9H_2O$. The water content of the fully hydrated mineral with the longest spacing 12·9 A., for which the name hydro-basaluminite is suggested, is still unknown. Specimens maintained under conditions of constant temperature and humidity approach constant weight very slowly. Hydro-basaluminite loses approximately 50 per cent by weight at 16° C. in ten days, before it reaches constant weight and yields only the powder pattern of basaluminite.

As the plastic mineral can only be preserved indefinitely in the presence of water, it may well be that if suitable precautions are taken in the collection and preservation of other clays and clay-like substances other hydro-varieties of known minerals may be discovered.

Structure of Co_2Al_9

IN an earlier note[1] the determination of the unit cell and space-group of the phase which exists in equilibrium with the restricted solid solution of cobalt in aluminium was described. The ideal composition was shown to be represented by the formula Co_2Al_9. The space-group is $P2_1/a$, and recent work has given more accurate values of the parameters, as follows: $a = 8{\cdot}5565 \pm 0{\cdot}0005$ A., $b = 6{\cdot}290 \pm 0{\cdot}005$ A., $c = 6{\cdot}2130 \pm 0{\cdot}0005$ A., $\beta = 94{\cdot}760° \pm 0{\cdot}005°$.*

From X-ray data obtained with molybdenum $K\alpha$ radiation it has proved possible to determine the structure by Fourier methods. Patterson projections on (010) and (001) together with a Patterson–Harker three-dimensional section at $(x\frac{1}{2}z)$ gave an indication of the positions of all twenty-two atoms in the unit cell. These positions were then confirmed, and the parameters refined, by two-dimensional Fourier synthesis. Final values of the parameters are:

Atom	x	y	z	
Co	0·333	0·615	0·265	± 0·001
Al_0	0	0	0	
Al_1	0·268	0·962	0·405	
Al_2	0·231	0·290	0·089	
Al_3	0·999	0·193	0·389	
Al_4	0·042	0·615	0·216	

The structure can be described as consisting of layers of aluminium atoms lying approximately in the planes $(0yz)$, $(\frac{1}{4}yz)$, etc., with cobalt atoms lying between the planes, slightly nearer to the planes at $x = \frac{1}{4}, \frac{3}{4}$. This layer structure is related to the habit of the crystals, which grow as plates parallel to the (100) plane. Each Co has a regular array of nine nearest neighbours—four in the plane $(\frac{1}{2}yz)$, four in the plane $(\frac{1}{4}yz)$ and one in the plane $(0yz)$, say; and these polyhedra of Al atoms are arranged with shared edges and corners in the $(0$ and $\frac{1}{2}yz)$ planes, and shared edges in the $(\frac{1}{4}, \frac{3}{4}yz)$ planes. Observed values of interatomic distances lie for Co-Al within the range 2·38–2·52 A., and for Al-Al within the range 2·70–3·00 A.; the former are low compared with Pauling's predicted values[2], while the latter agree reasonably well.

An estimate of the number of electrons contained within the Co peak in the $(h0l)$ and $(hk0)$ Fourier syntheses, based on the assumption that the electron density between atoms is zero, indicates that the cobalt atom has of the order of two electrons more than its normal number of 27. This is in agreement with Raynor's theory[3] that in the alloys of transitional metals with aluminium, the transitional metals act as electron acceptors by filling up their atomic orbitals[4]. Also the radius of a Fermi sphere, corresponding to a number of electrons per unit volume calculated on the basis of Raynor's theory of electron acceptance by cobalt, is 1·948 A., which agrees well with the spacings of 1·959 A. and 1·939 A. of the strongest two lines on the powder photograph of Co_2Al_9.

---

* Note that here the x and z axes have been interchanged, compared with those given in ref. (1).

The structure will be described in detail elsewhere.

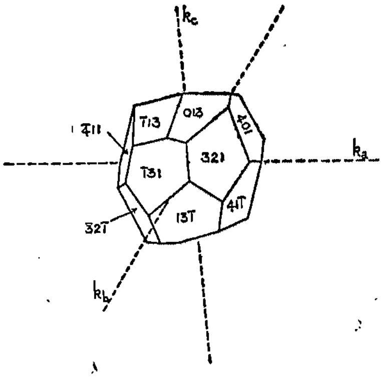
[3] Raynor, G. V., *Phil. Mag.*, **36**, 770 (1945).
[4] Pauling, L., *Phys. Rev.*, (11), **54**, 899 (1938).

It is most gratifying to note the agreement of the results of Mrs. Douglas' determination of the crystal structure of Co_2Al_9 with the theory that, in aluminium-rich alloys, transitional metal atoms absorb electrons by filling up their atomic orbitals[1]. This work emphasizes the importance of crystallographic studies in the development of alloy theory.

Mrs. Douglas shows, in her letter, that the radius of the Fermi sphere, calculated according to the theory of electron acceptance, is in agreement with the spacings of the strongest two lines in the diffraction pattern. Since Mrs. Douglas very kindly informed us of her crystal structure results prior to publication, it was possible to make an independent examination of the Brillouin zone structure of the compound, which confirms her findings.



The strongest two lines in the diffraction pattern appear to result from the overlapping of reflexions from the ($\bar{4}11$), (321), (401), (013), ($\bar{1}13$) and ($\bar{1}31$) planes. In k-space these planes define a closed volume of the form shown in the accompanying diagram. The perpendicular distances of these planes from the origin of k-space lie between the closely similar values of 0·2543 recip. A. (for planes of the type $\bar{4}11$ and 410) and 0·2570 recip. A. (for planes of the type $\bar{1}31$ and $\bar{1}13$). Fermi spheres having these radii correspond respectively to 2·1 and 2·15 electrons per atom; the 'average' Fermi sphere, with radius equal to the mean perpendicular distance of all six planes from the origin, corresponds with 2·12 electrons per atom. The bounding planes of the Brillouin zone are therefore touched by the Fermi sphere when 2·12 electrons per atom are present. This is in very close agreement with the value of 2·125 electrons per atom, characteristic of the experimentally determined composition of Co_2Al_9 crystals extracted from aluminium-rich aluminium–cobalt alloys[2], the number of electrons per atom absorbed by cobalt[1] being taken as 1·71. These results add further support to the view that compounds of this type are properly to be regarded as 'electron compounds'[3].

Decay of Barium-139

The isotope Ba^{139} is radioactive with a half-life of 85 min. decaying to La^{139} by β^- emission. This activity was first reported by Pool and Cork[1]. Kalbfell and Cooley[2], using absorption methods, have reported a continuous β-spectrum with a maximum energy of 1 MeV. accompanied by γ-radiation of energy 0·6 MeV., while Born and Seelmann-Eggebert[3] report a maximum β-energy of 2·3 MeV. also by an absorption method.

In the present experiments investigation of the activities was made by means of a thin-lens β-ray spectrometer and by absorption and coincidence techniques.

Ba^{139} was produced by bombarding fused barium nitrate with 7 MeV. deutrons in a cyclotron. After bombardment the barium was separated from lanthanum and sodium and precipitated in the form of amorphous carbonate. (Lanthanum activity is produced by Ba-dn-La reaction and Na^{24} by Al^{27}-$n\alpha$-Na^{24} reaction with the aluminium target plate.) After this separation the β- and γ-radiation both decayed with a period of 84 ± 1 min. and no contamination could be detected over five half-life-times.

Fig. 1 shows the momentum distribution of the β-spectrum obtained in the β-ray spectrometer. This

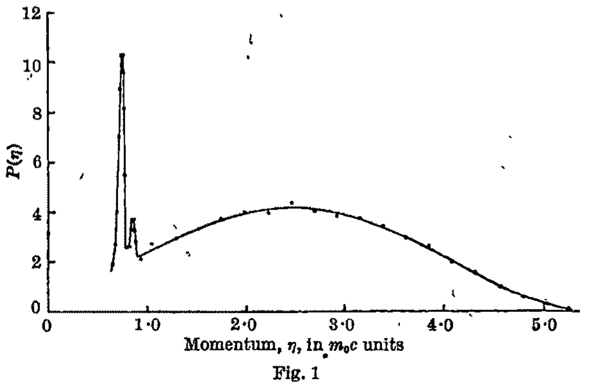

Fig. 1

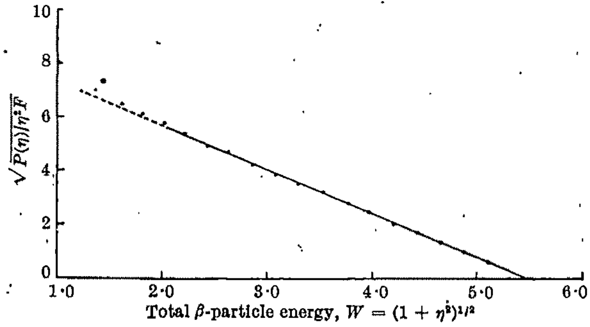

Fig. 2

spectrum was obtained using a source of thickness 3 mgm. cm.$^{-2}$ and about 1 sq. cm. in area deposited on thin aluminium foil. The spectrometer resolving power was about 15. A Fermi plot of this spectrum is shown in Fig. 2. This indicates a maximum kinetic energy of 2·27 ± 0·02 MeV. In addition to the continuous β-spectrum two conversion electron groups were found having energies of 126 ± 0·5 keV. and 159 ± 2 keV. These groups correspond to the K and L electrons from the conversion of a γ-ray of 163 ± 0·5 keV. in the product nucleus. From Fig. 1 it is estimated that the ratio of conversion electrons to β-particles is 5 ± 1 per cent and the ratio $N_K/N_L \sim 6$.

Fig. 3 shows the absorption curve obtained using lead absorbers and a brass γ-counter, the β-particles being absorbed in polythene. The majority of the radiation has a mass absorption coefficient of 1·38 cm.^{2} gm.$^{-1}$ corresponding to the 163 keV. γ-ray. About 10 per cent of the counting rate appears to be due to a harder γ-ray of energy 1·05 ± 0·1 MeV. By the use of calibrated β- and γ-counters the intensity of the γ-radiation was estimated. Expressing these intensities as a percentage of the total number of disintegrations, the number of quanta escaping is estimated as 26 ± 3 per cent for the 163 keV. γ-ray and ∼ 0·6 per cent for the 1 MeV. γ-ray. An attempt was made to confirm the energy of this harder γ-ray by means of Compton recoil electrons in the β-ray spectrometer; but the relatively low intensity available together with the short life-time prevented any useful results being obtained by this method.

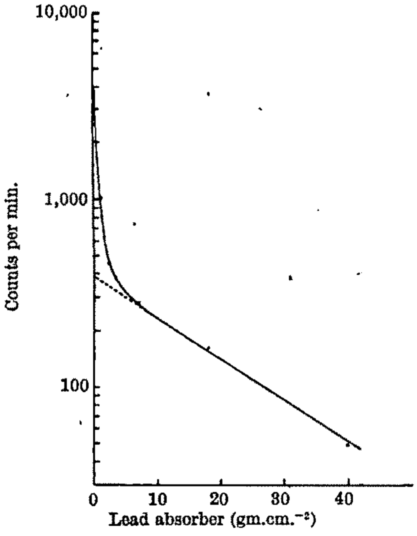

Fig. 3

Coincidences were obtained between β-particles and γ-rays and between β-particles and conversion electrons. From the latter the percentage of conversion electrons was estimated and the result was in good agreement with that obtained by the spectrometer. The product nucleus is La^{139}, which has a spin of 7/2 in the ground-state, and it was thought that the 163 keV. level might have a measurable metastable life-time. No such life-time could be detected with our equipment, which had a lower limit of 10^{-7} sec.

Preparation of Pure Iron-59 of High Specific Activity

THE preparation of Fe^{59} by (slow n,γ) reaction on potassium ferrocyanide has been described by Dewhurst and Miller[1]. The reaction is of the Szilard – Chalmers type, so that the active iron could be obtained by precipitation on aluminium hydroxide at specified pH; three precipitations were necessary to obtain 'a clean 47-day activity'.

We have irradiated hydroferrocyanic acid in the Harwell low-energy pile (G.L.E.E.P.), this compound being chosen to avoid formation of the short-lived K^{42} which emits very penetrating β- and γ-radiation and which is produced in far greater amount than is the Fe^{59}, when potassium ferrocyanide is irradiated. From the irradiated hydroferrocyanic acid, which is blue, Fe^{59} may be obtained very simply by extraction with dry, dilute ethereal hydrochloric acid in a Soxhlet apparatus.

After irradiation for a month (slow neutron flux 2·5 × 10^{10}/sq. cm./sec.), the activity of the solid was determined before and after extraction with a Geiger – Müller tube having a window thickness of 4 mgm./sq. cm. It was found that 50 per cent of the total activity remained. The activity of the hydroferrocyanic acid was too low (70 counts/min./mgm.) to permit an absorption curve, owing to self-absorption, so that it is not possible to state how much of the total activity is Fe^{59}. The other 50 per cent of the total activity was accounted for in the ethereal extract, so that no loss of activity, say as gaseous products, occurred.

Most of the activity which could be extracted was extracted in the first hour; after two and a half hours no further extraction occurred. The blue colour partially faded during extraction.

The ethereal extract was taken just to dryness and the greenish-black residue digested with water for two hours

(*a*) The aqueous extract contained at least 90 per cent of the activity extracted by the ether and was proved to be radioactively pure Fe^{59} by its absorption curve[2].

(*b*) The residue was partially soluble in alcohol. Removal of the alcohol from the extract left a black oily material which carried the remaining 10 per cent of the extracted activity. An absorption curve showed this to be almost pure C^{14}.

(*c*) The residue from the successive aqueous and alcoholic extractions was greenish-black and carried very little, if any, activity.

The amount of iron extracted during this process is small, about 300 μgm. per gm. of hydroferrocyanic acid, as determined spectroscopically. Parallel experiments showed that this iron is not produced by irradiation, but is extracted also from unirradiated hydroferrocyanic acid. The specific activity of the Fe^{59} is therefore about 1·5 mc./gm. It is hoped to repeat and extend these experiments, and also to obtain higher specific activity, with samples irradiated in the bigger pile now in operation at Harwell.

Distribution of Ice-Particle Nuclei in the Free Atmosphere

CWILONG[1] has determined the highest temperatures at which ice forms in the cloud produced by adiabatic expansion in a Wilson cloud chamber. He found a threshold temperature of $-41{\cdot}2 \pm 0{\cdot}2^\circ$ C. for air which had been cleaned by repeated expansions, and of $-32 \pm 1{\cdot}0^\circ$ C. for outdoor air at Oxford. He has since repeated the experiments with outdoor air on the Jungfraujoch[2], and on the Atlantic and Pacific Oceans[3]: he found the clean air threshold on all but one occasion.

During the past year an apparatus similar to that used by Cwilong has been fitted to a Halifax aircraft of the Meteorological Research Flight at Farnborough, and measurements have been made in flight on four occasions. On each flight the threshold temperature for the free air was determined at two or three levels. On two of the flights there were pronounced anticyclonic inversions at about 5,000 ft., while on the other two the *radio-sonde* ascents showed no marked inversions, though stratus cloud or a haze-top showed that the air was stratified.

The clean air threshold was found in all measurements above the inversions, the stratus, or the lowest haze-top, while the measurements below these levels gave -33° C. to -35° C. On one occasion two haze-tops were observed, and the clean air threshold was found above the lower. The greatest height at which the threshold has been observed to be above -41° C. is 8,000 ft., while the lowest at which the clean air threshold has been found is 6,000 ft. These results were obtained in winter and early spring, and they suggest that the nuclei active at -32° C. are only present in air which has recently been in contact with the surface.

The greatest height reached was 18,000 ft., and there the threshold was measured as -44° C. Clean air from a compressed air cylinder was also examined at this height, and gave -44° C. It is not certain whether this is a true variation of the threshold or an instrumental effect. The expansion ratios were controlled to give final temperatures accurate to $\pm 0{\cdot}5^\circ$ C., and the apparatus will detect nuclei present in concentrations of 10/litre.

I am indebted to the Director of the Meteorological Office for permission to make the flights, and publish the results, and to Dr. Frith of the Research Flight for his unfailing helpfulness in the air and on the ground. Prof. G. M. B. Dobson suggested this research, and it is a pleasure to acknowledge his continued interest and many valued suggestions.

Frictional Electrification of Sand

A VERY simple experiment seems to have a meteorological significance.

A small plate about one square inch in area was attached to the insulated quadrant of a Dolezalek electrometer. A cupful of fairly dry sand was then poured through a funnel and allowed to fall some three feet to the floor. The electrometer plate was three yards away from the dropping sand. The passage of the sand through the funnel took about half a minute, and while it was dropping there was no effect on the electrometer; but soon after, the electrometer began to show a deflexion which continued to increase for three or four minutes. This deflexion corresponded to the plate receiving positive charge. Having reached a maximum deflexion of a volt or so, the deflexion commenced to decrease, and continued to do so for a few more minutes and finally came to rest near its original zero position. In this stage the plate must have been receiving negative charge. That this decrease was not due to faulty insulation was checked by another experiment in which the plate was momentarily earthed when the deflexion reached its maximum, and it then charged up negatively in the last few minutes.

As the whole phenomenon occurs after the sand has ceased to drop, any explanation based on induction must be ruled out and the plate must have received positive charge through the air in the first few minutes, and an approximately equal amount of negative charge in the last few minutes. What is the source of these charges and why do the positive arrive first? The sand in its passage through the funnel gets charged negatively by friction, as is easy to show by letting a little of it fall into a metal cup connected to the insulated quadrant of the electrometer, and the question is therefore where does the positive charge come from? It was thought at first that the falling sand might, by friction, electrify the air, producing positive and negative ions which diffuse at different rates. There are several reasons against this, and the main one is that the kinetic energy of the ions would only be sufficient to charge up the plate to a very small fraction of a volt. The particles must, therefore, be very much larger, and one is driven to the conclusion that they are dust particles of the sand itself. Furthermore, they must be a mixture of small particles with a positive charge and larger particles with a negative, because the carriers of the positive diffuse, or are carried by convection, quicker than the carriers of the negative.

The frictional effect of the funnel always charges the sand negatively whatever the size of the particles, so the final conclusion reached is that the sand rubbing on itself must produce positive charges on the smallest particles and negative charges on the larger.

The electrometer had an approximate capacity of 50 E.S.U., and considering the smallness of the collector plate and its large distance from the dropping sand the total amount of charge produced by the sand is surprisingly large. The meteorological application is, of course, obvious. When sand is blown about on a big scale, very large charges must be produced, and the different rates of diffusion or convection separate the charges. The comparative largeness of the particles means that the motion is little interfered with by the electrostatic forces due to the charges on the various particles, so that the diffusion or convection will result in very large potential differences being set up.

Many years ago, on the Salonika front, I noticed that when a dust storm was approaching my wireless station the aerials started sparking violently when the dust cloud was some way off; sparking then ceased for a while, to recommence with equal violence when the storm hit the camp. This has an uncommon resemblance to the electrometer experiment, the first sparking being due to particles too fine to be visible.

Influence of Reactive Feedback Networks on the Response of Galvanometers

In the course of an investigation into servo circuits and self-balancing systems in general I had opportunity to examine the effect of reactive elements in the negative feedback networks of electronic amplifiers on the response characteristics of current measuring instruments. Detailed mathematical analysis revealed a number of facts which make it appear probable that a reactive feedback circuit can be used as an alternative to other negative feedback circuits in galvanometers, such as the twin-coil meter[1] or the mirror-and-photocell instrument[2,3,4], without interference with the mechanism of the instrument itself.

If a voltage v is applied to an electronic amplifier of gain A in the output of which is connected a network consisting of the resistances R_1 and R_2, the condenser C and the inductance L, and if also the voltage appearing on the junction between L and C is fed back in series with and negatively to the input voltage, then the frequency response of the amplifier is made to depend on the characteristics of the feedback circuit (Fig. 1). If the output is connected to a current instrument, via a buffer stage, the response of the pointer will depend both on the voltage-time function of the input and the characteristics of the feedback circuit. In this case, the differential equation governing the deflexion-time function is an inhomogeneous one of the fourth order, the forcing function being the input voltage v. If, however, the damping and frequency of the feedback circuit and those of the meter are made equal, for example, by suitable choice of values of the circuit constants, the equation reduces to one of the second order. This equation is similar to the one governing the meter deflexion itself (that is, in the absence of the feedback network), except that the coefficient of the zero order term now contains an additional term proportional to A. The effect of this feature is that while the damping remains unaltered, the natural frequency calculated from the equation can be increased freely by the simple expedient of suitably adjusting the gain of the amplifier. The mathematical treatment bears considerable resemblance to the resonant shunt method of influencing the response of galvanometers, which is, indeed, a special case of the present device[5,6,7].

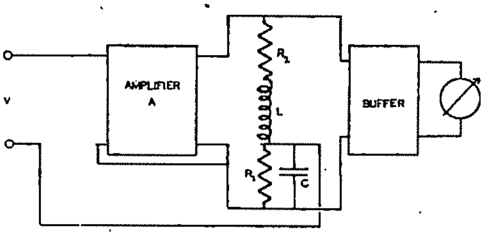

Fig. 1

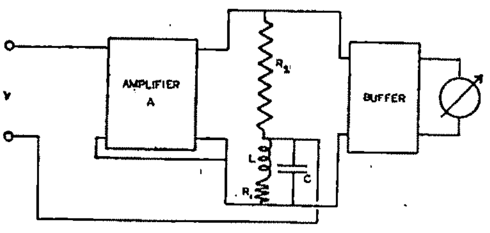

Fig. 2

The result is formally identical with the conditions obtaining in any of the other electrical or electro-optical feedback galvanometers quoted in the references; in the present case, however, there is no need for any additional mechanical attachments to the instrument or any modifications of its internal design. If the instrument is originally overdamped, it can be brought back to 'dead beat' conditions by a simple gain control operation. A preliminary experiment to check the theory was carried out with an Evershed and Vignoles recording milliammeter, the dashpot of which was filled with glycerine. A directly coupled amplifier was adjusted until dead beat conditions were re-established. In this way it was possible to make the response of the meter extremely fast, the response time being of the order of 1/10 sec.

Another possibility of using reactive feedback networks to influence the response of a meter lies in placing the inductance L into the other arm of the network (Fig. 2). Here the conditions are exactly analogous. The galvanometer equation, adapted to include the special feature of the feedback circuit, is again of the fourth order, reducing to one of the second order, if the feedback network is 'tuned' in frequency as well as damping to the galvanometer. But now the coefficients of both the zero and first-order term contain an expression proportional to A. Thus the apparent damping as well as the apparent frequency is affected, the latter being reduced as A is increased. This circuit is therefore particularly useful in conjunction with underdamped instruments. It returns them to conditions of critical damping or, if desired, to over-critical behaviour.

It is probable that similar circuits to the ones discussed can be used for affecting the characteristics of a meter in any desired way, by suitably combining reactive and resistive components or by a sequence of circuits of the types mentioned, one feeding into the next and finally into the meter. The possibility of a general mathematical approach is being investigated.

A detailed paper is to be published shortly.

Biological Properties of a Substance Isolated from Wheat Middlings and of Hydroxymethylfurfuraldehyde

Following on the description many years ago[1] of a growth-inhibiting constituent of yeast, a number of plant extractives[2] and pure substances[3] have been reported to possess similar activity. A distinctive feature in the case of most of them is that in cultures *in vitro* the growth of connective tissue cells is inhibited, but not that of epithelia. From this the conclusion was drawn that such action, if exerted *in vivo*, would lead to the retardation of growth in young animals since this depends upon the growth of their connective tissue, without interference with the vitality of such other tissues as the skin and blood-forming organs, the cells of which continue to multiply throughout normal life. A further inference was made that the growth of tumours might similarly be inhibited, since this too depends upon a parallel growth of stroma. These expectations were, in fact, to some extent realized[4], but owing to the unsatisfactory nature of the material used the experiments were unconvincing.

It now appears that action of this kind is not specific, being shown in varying degree by a number of aldehydes[5,6], lactones[3,7] and other substances[8] containing unsaturated groups.

In the course of further attempts to isolate the naturally occurring agent from plant sources a substance has been prepared from wheat middlings which is clearly of carbohydrate nature but has not yet been completely identified. In very brief outline the process is the following. Wheat middlings are quickly extracted with 80 per cent alcohol (½ hr. stirring; all processes must be expeditiously conducted), the extract concentrated under diminished pressure below 60° to a small volume, washed with benzene, concentrated below 60° nearly to dryness, washed again with benzene, and excess absolute alcohol then added. The sticky solid precipitated is then twice extracted with hot absolute alcohol and the insoluble residue triturated with cold 95 per cent alcohol. The substance is then taken up in hot 95 per cent alcohol and the solution is evaporated under low pressure. A modification of this procedure has been employed in later experiments but the statements in the text apply to material made as described. Tested on young rats, it has been found to arrest growth at a daily dose of about 1 mgm., given by the mouth. The effect is immediate and ceases directly administration is discontinued.

During the progress of the work the probability seemed to emerge that a characteristic structural feature was a furanose group, for the product was convertible by acid to hydroxymethylfurfuraldehyde. This substance had already been found effective in arresting the growth of rats, at a dose of about 2 mgm. per day, and similar activity was shown by the relatively insoluble polymer which tends to form spontaneously when hydroxymethylfurfuraldehyde, prepared in the pure state from cane sugar, is kept.

When tested on rats bearing the Walker carcinoma, all these three substances have been found to cause retrogression of the tumours, taking effect in about a week. The dose necessary for the purpose is considerably larger, namely, about 15–45 mgm. per rat per day in the case of hydroxymethylfurfuraldehyde; in all three cases it was noted that at this high level of dosage the increase of body-weight is no longer arrested but, if anything, accelerated.

In a future communication more details will be given and, it is hoped, an indication of the precise nature of the active substance which we have isolated from wheat middlings, or, in some experiments, from malt extract. The two are not necessarily identical though they appear to have similar properties.

We wish to express our obligation and thanks to Sir Robert Robinson for stimulating help and advice.

Assay of *nor*Adrenalin and Adrenalin in Extracts of Nerves and Tissues

Recent investigations have shown that the sympathomimetic activity present in several organs and in large amounts in adrenergic nerves, for example, the splenic nerves of cattle, is chiefly due to lævo-*nor*adrenalin or *l*-arterenol, which has been identified by quantitative biological and colorimetric tests (Euler[1,2]). By using the cat's blood pressure in conjunction with the fowl's rectal cæcum (Barsoum and Gaddum[3]) as test preparations, showing activity ratios for *l*-adrenalin and *l*-*nor*adrenalin of 1 : 2–4 and 20–30 : 1 respectively, adrenalin has been detected in extracts of spleen, and splenic nerves, in amounts corresponding to 1–4 per cent of that of *nor*adrenalin.

The biological assays have been facilitated by using a method of purification, depending on adsorption of the sympathomimetic activity on aluminium hydroxide (Shaw[4]). In order to increase the amount recovered with this method, the aluminium hydroxide, instead of being added as such, was formed in the trichloracetic acid extract of the organs by adding aluminium sulphate and sodium hydroxide. Adsorption was carried out at *p*H 7, and was practically complete even with small amounts of aluminium hydroxide. The washed precipitate was dissolved in sulphuric acid, and the aluminium sulphate removed by precipitation with four volumes of ethanol at *p*H 3·5. About 70 per cent of the sympathomimetic activity was recovered by this procedure, and, since the extracts were only slightly coloured, and showed almost no contamination with other substances likely to interfere with the tests, it could be used directly for biological and colorimetric assays. The relative proportions of adrenalin and *nor*adrenalin were the same as in the crude extracts. For spleen and splenic nerves from cattle, the following ranges of figures may be regarded as representative.

Tissues (cattle)	*l*-adrenalin-HCl	*l*-arterenol-HCl	
Splenic nerves	0·2 – 0·5	10–20	μgm./gm.
Spleen	0·05–0·12	2–4	,,

Alloxan Diabetes in Dogs with Renal Pedicles Clamped

Jiménez Díaz, Grande Covián and De Oya[1] have reported that in dogs in which the vessels of both kidneys were clamped, the intravenous injection of alloxan in doses of 80–100 mgm./kgm. failed to produce either the hyperglycæmia or uræmia observed in controls in which the clamping was omitted. They postulated that "contact between alloxan and the kidney is apparently necessary for the display of the full diabetogenic effect". However, diabetes was observed on injecting alloxan during clamping of both renal pedicles in rats[2,3] and rabbits[4]. Recently, Jiménez Díaz and Souto Candeira[5] postulated that "alloxan produces some kind of renal injury which accentuates diabetes. . . . In conclusion, the kidney is apparently not necessary for the production of alloxan diabetes, but renal injury produced by alloxan would contribute to accentuate it."

Experiments were performed on dogs anæsthetized with 'Nembutal' (33 mgm./kgm. intraperitoneally). Alloxan was injected intravenously (75 mgm./kgm.) in 25–45 sec. The fasting blood sugar-level was determined before and 24–48 hr. after the injection of alloxan. Some of the animals died before the end of 48 hr., so these have not been considered as valid. Out of fifteen controls thirteen developed diabetes after alloxan injection. The clamping of both renal pedicles followed by the alloxan injection had a clear protective effect since only two dogs out of eleven developed a full diabetic condition (see accompanying table).

Diabetes due to intravenous injection of alloxan (75 mgm./kgm.) in dogs anæsthetized with 'Nembutal' (33 mgm./kgm. intraperitoneally)

Procedure	Diabetic
Controls	13 out of 15
Renal pedicles clamped	2 ,, 11
Renal vessels clamped	3 ,, 8
Renal nerves clamped	2 ,, 9
Spleen vascular pedicle clamped	0 ,, 6
Renal denervation and clamping	1 ,, 7
Bilateral nephrectomy before alloxan	5 ,, 5
Bilateral nephrectomy 2–12 hr. after renal clamping and alloxan	7 ,, 11

When clamping was limited to the vessels (both renal arteries and veins), excluding nervous structures, only three out of eight dogs which were injected with alloxan developed diabetes. Likewise the clamping of both renal pedicles, excluding only the vessels, protected seven out of nine dogs so injected.

Alloxan injected immediately after denervation of both renal pedicles, leaving the renal arteries and veins intact (without clamping), also protected six out of seven dogs.

Alloxan injected after bilateral nephrectomy caused an intense diabetes in all of five dogs. The same result was observed in seven out of eleven dogs in which bilateral nephrectomy was performed 2–12 hr. after clamping and injecting alloxan.

Finally, after injecting the alloxan after clamping the vascular pedicle of the spleen and maintaining the vessels clamped for 15 min. after the injection, all of six dogs failed to develop diabetes.

These results confirm the observation that alloxan injection, immediately after clamping of both renal pedicles in the dog, fails to produce diabetes although microscopically lesions of variable degree in some β-cells of the islets have been found. The same protection has been produced: (*a*) by clamping either the renal vessels only or the nervous structures; (*b*) injecting the alloxan after denervation of both renal pedicles leaving intact the vessels; (*c*) injecting the alloxan after clamping the vascular pedicle of spleen.

Furthermore, the injection of alloxan after bilateral nephrectomy was followed by a full diabetic condition. Thus it seems that the presence of intact kidneys is not necessary in order to obtain diabetes after alloxan injection.

However, uræmia seems to increase the severity of alloxan diabetes, since when nephrectomy is performed 2–12 hr. after the alloxan injection in dogs with both renal pedicles clamped, diabetes developed in seven out of eleven dogs.

The results of these experiments suggest the possibility that some kind of vasomotor reflex in the pancreas can be elicited from the renal pedicles due to clamping, as was suggested by Gold[2]. In order to confirm this hypothesis, several experiments were carried out, injecting 3 c.c. of indian ink into the descending aorta, using a cardiac catheter introduced through the left carotid artery. The pancreas was removed 3 min. after the indian ink injection. The results were as follow: in four control dogs the pancreas showed a dark colour of variable intensity due to the indian ink injection; but in four dogs in which both renal pedicles were clamped immediately before the injection, the pancreas showed its normal colour or was just a little darker. Microscopical examination of the islets in the controls showed many capillary vessels with plenty of indian ink, while in the islet vessels of the clamped animals scarcely any indian ink was observed. These experiments seem to confirm the hypothesis suggested by Gold that a vaso-constrictor reflex in the pancreas can be elicited by the mechanical procedure of clamping, and thus prevents injected alloxan reaching the islets in sufficient concentration to produce destruction of β-cells and diabetes.

Effect of Hypophysectomy on Glycogen Deposition in Isolated Muscle

RESULTS of experiments previously reported from this Institute in 1944 [1] indicated that when extracts of the anterior pituitary gland were administered to rats, insulin did not exhibit its usual action in promoting glycogen deposition in muscle as studied on the rat's diaphragm according to the technique of Gemmill[2]. In 1945 Cori *et al.*[3] reported the results of experiments on the effect of anterior pituitary extract and of insulin on hexokinase activity in tissue extracts obtained from rats.

It was found that when anterior pituitary extract was either injected into the intact animal or added to tissue extracts, hexokinase activity was inhibited. However, when insulin was added to such extracts, it appeared that this latter hormone released hexokinase from the anterior pituitary extract inhibition. Further, Cori considered that insulin *per se* did not enhance hexokinase activity.

As our investigations were carried out on intact muscle, it is difficult to make any strict comparison with the experiments of Cori.

It seemed, however, that any direct effect of insulin on hexokinase activity would be best investigated on hypophysectomized animals. Thus the inhibiting effect of the anterior pituitary on the hexokinase activity would be abolished, resulting in increase of glycogen deposition as compared with normal animals; and if a further increase occurred as a result of the addition of insulin it would be reasonable to assume that insulin exerted a direct action on hexokinase activity.

On the other hand, insulin should have no effect on the deposition of glycogen in the diaphragm of the hypophysectomized rats if its action were limited to the release of anterior pituitary inhibition.

In our experiments the methods employed have been reported in previous papers[1,4]. Hypophysectomy was performed according to the technique of Thompson[5]. Ten to fourteen days were allowed to elapse between the operation and excision of the diaphragm. A summary of the results obtained are shown in the following table.

Normal rats Mean of 28 animals			Hypophysectomized rats Mean of 20 animals		
Glycogen %			Glycogen %		
Without insulin (*a*)	With insulin (*b*)	Increase (*c*)	Without insulin (*d*)	With insulin (*e*)	Increase (*f*)
0·269	0·53	0·261	0·364	0·766	0·402

For columns (*a*) and (*d*) $t = 4 \cdot 19$ P 0·001
(*c*) and (*f*) $t = 5 \cdot 6$ P 0·001

From these results it appears that hypophysectomy increased the hexokinase activity in the isolated diaphragm of the rat and that it is further enhanced by the addition of insulin. Thus we are of the opinion that insulin has a direct effect on hexokinase activity.

We would like to express our sincerest thanks to Mr. A. F. Doutch for the statistical analysis.

Cytochemical Demonstration of Ketosteroids

IN a number of cytochemical papers[1,2] it has been claimed that α-hydroxyketones, such as deoxycorticosterone, give a purple colour with reduced fuchsin in Feulgen's 'plasmal' reaction. In this reaction the material under test is treated with cold saturated aqueous mercuric chloride solution, then with reduced fuchsin. According to Dempsey *et al.*[3], aqueous mercuric chloride oxidizes the hydroxyketone to an aldehyde, which then reacts with reduced fuchsin.

We have now studied this reaction with three pure samples of deoxycorticosterone, one kindly supplied by Prof. T. Reichstein, Pharmazeutische Anstalt der Universitaet Basel, one kindly supplied by the British Drug Houses, Ltd., and the other prepared by one of us (C. W. S.) by hydrolysis of a sample of deoxycorticosterone acetate kindly supplied by Dr. F. T. Hewett, Organon Laboratories, Ltd., London, S.W.19. The sample prepared from the acetate was purified by sublimation at 0·001 mm. and recrystallized from ether.

With none of these samples have we been able to obtain any evidence of oxidation of deoxycorticosterone to an aldehyde by aqueous mercuric chloride.

We conclude that this technique cannot be relied upon to demonstrate the cytological location of α-hydroxyketones. Our experiments have been restricted to one such compound; but the facts of organic chemistry indicate that the α-hydroxyketo-grouping in deoxycorticosterone may be regarded as typical, and only atypical α-ketols, if any, will react as postulated by Dempsey and Wislocki.

p-Aminobenzoic Acid a Growth-Factor for Certain Brewer's Yeasts

MOST of the single-cell strains of English brewery top fermentation yeasts so far examined grow well at 25° C. in forty-eight hours in a synthetic glucose-mineral salts medium, containing $(NH_4)_2HPO_4$ as the sole source of nitrogen and biotin, pantothenic acid and inositol as accessory growth factors ('bios').

However, two single-cell strains, isolated from different breweries, failed to grow even after six days incubation at 25° C. in the medium containing the three factors mentioned above and in addition riboflavin, aneurin, nicotinic acid and pyridoxin. The missing factor proved to be *p*-aminobenzoic acid, addition of 0·01 μgm. per ml. of which induced heavy growth in the presence of other essential bios factors. One strain, designated 'Yeast 45', required biotin as an essential growth factor in addition to *p*-aminobenzoic acid, pantothenic acid (or β-alanine) being strongly stimulatory, but not essential for good growth. The other strain ('Yeast 47') required both biotin and pantothenic acid (or β-alanine) in addition to *p*-aminobenzoic acid as essential bios constituents, while inositol and a mixture of riboflavin, aneurin, nicotinic acid and pyridoxin each has a stimulatory effect.

While *p*-aminobenzoic acid is recognized as a growth factor for many organisms, of which *Acetobacter suboxydans*, *Clostridium acetobutylicum*, *Lactobacillus arabinosus* and *Neurospora crassa* have been employed for microbiological assays of *p*-aminobenzoic acid, I am not aware that strains of brewer's yeast exacting towards *p*-aminobenzoic acid have been reported. The response of 'Yeast 45' and of 'Yeast 47' to *p*-aminobenzoic acid is so striking as to suggest that either organism may prove suitable for the microbiological assay of the vitamin.

A Test for Mutagenicity of Methylcholanthrene

RECENT results by Strong[1,2] and by Carr[3] on mice, and by Demerec[4] on *Drosophila*, have focused interest on a possible connexion between mutagenicity and carcinogenicity, which in the past has often been claimed on theoretical grounds. While Auerbach[5] failed to produce mutations by injection of 1 : 2 : 5 : 6 dibenzanthracene into *Drosophila*, Demerec obtained positive results with a number of carcinogens, including dibenzanthracene and methylcholanthrene, when these were administered to the flies in the form of aerosols. Still a different possibility of administration is by addition of the carcinogen to the food of the larvæ, since fluorescence tests carried out by Fabian and Matoltsy[6] have shown that methylcholanthrene given in this way enters into the gonads. An experiment using this method was under way when Demerec's first results were published, and its outcome will be briefly presented. The food contained powdered methylcholanthrene in a concentration of 0·01 per cent. No live yeast was added to the culture vials, in order to avoid complications through offering the larvæ an alternative supply of untreated food. Fluorescence tests showed that methylcholanthrene or a fluorescent derivative of it had penetrated into the gonads of the imagines which emerged in the treated vials. In spite of this, no evidence for mutagenic action of methylcholanthrene was obtained in tests for sex-linked lethals. Only two lethals were found in 1,012 chromosomes from treated ♂♂ (compared with one in 1,007 control chromosomes), and three in 1,026 chromosomes from treated ♀♀ (compared with two in 1,014 control chromosomes).

The discrepancy of this result with that obtained by Demerec seems to prove the superiority of the aerosol method for this type of experiment. However, closer inspection of the data makes this doubtful. According to the data shown by Demerec at the Eighth International Congress of Genetics, aerosol treatment with methylcholanthrene produced 25 lethals in 4,671 treated *X*-chromosomes, as compared with 28 in 10,006 control chromosomes, a statistically significant difference. On the other hand, there is no significant difference between Demerec's positive and our negative result in the treated series. It may well be that the feeding method, when done on a comparably large scale, might be as effective in demonstrating the mutagenic capacity of methylcholanthrene as the aerosol method. Whatever method is used, it seems obvious that only experiments involving very large numbers of cultures will be able to reveal mutagenicity in substances of either low mutagenic potency or else low power of penetration to the chromosomes of the germ cells.

Fungal Mutations Obtained with Methyl Xanthines

IN studying the ability of various chemicals to induce mutations in fungi, we found a very striking effect of the two purine compounds, caffeine and theophylline, which seems to be of interest from several points of view.

Most of the experiments were performed with the ascomycete, *Ophiostoma multiannulatum*, conidia of which were treated with the chemicals under test. Since we looked for specific actions, only clear-cut physiological mutations implying biochemical deficiencies were isolated and identified. The technique is described in another paper[1].

Of the purine compounds tested, caffeine and theophylline showed the strongest activity. An addition of 0·05–0·15 per cent caffeine to a growing conidial culture causes a decrease in the multiplication rate of the conidia. With 0·2 per cent or more of caffeine, growth is completely inhibited, and the conidia are killed at a rate which seems to be a function of the concentration of caffeine present. The corresponding figures for theophylline are 0·2–0·5 per cent and 0·6 per cent respectively.

In platings made from such cultures with inhibited growth, where most of the conidia have been killed, as well as from conidial suspensions in pure caffeine solution, a great number of morphologically deviating monoconidial mycelia appeared.

For certain reasons we chose to examine the possible mutagenic effect of these substances in concentrations which just inhibit the growth, and slowly kill the conidia. It was found that under the experimental conditions, caffeine reached its maximal mutation-producing effect in five days, when 0·2 per cent conidia were still alive. The same seemed to be valid for theophylline.

This technique probably does not exclude the possibility of nuclear divisions (in spite of the inhibited growth), and the mutations found are, therefore, if they are induced, not certainly to be looked upon as 'zero-point mutations' in the sense of Demerec and Latarjet[2].

As appears from the accompanying table, about the same percentage of biochemical mutations was obtained from all the four platings of conidial suspensions treated with caffeine for 5–8 days, namely, c. 1 per cent. Theophylline produced a poorer yield, *c.* 0·6 per cent. These values are, in comparison with those obtained with other chemicals, very high. X-ray irradiation usually gives in *Ophiostoma* 1·8 per cent biochemical mutations, and nitrogen mustard has sometimes given up to 1·3 per cent. Untreated,

	Number of mutants isolated after treatment with							
	0·2 % caffeine					0·6 % theophylline		
	Treatment in days				Total	Treatment in days		Total
	5	6	7	8		4	6	
Factor required :								
Reduced sulphur	—	—	—	—	—	—	1	1
Arginine	1	3	—	—	4	1	2	3
Lysine	1	1	1	—	3	—	1	1
Methionine	1	—	—	—	1	—	1	1
Other amino-acids	1	—	1	—	2	—	1	1
Hypoxanthine	3	1	1	1	6	—	—	—
Uracil	—	—	—	—	—	—	1	1
Inositol	7	5	5	2	19	2	5	7
Niacin	4	3	—	1	8	—	—	—
Biotin	—	1	—	—	1	—	—	—
Not identified	—	—	—	2	2	1	1	2
No. of mutants	18	14	8	6	46	4	13	17
Conidia isolated	2264	1202	880	398	4744	635	2174	2809
% living conidia	0·20	0·08	0·04	0·03	—	0·38	0·25	—
% mutant conidia	0·8	1·1	0·9	1·5	1·0	0·6	0·6	0·6

growing conidial cultures of *Ophiostoma* from which the conidia for these experiments were taken have never been found to contain more than 0·06 per cent biochemically deficient conidia; in most control experiments none was found.

Of the other methylated purines which we have so far synthesized, only 1,7-dimethyl hypoxanthine has been tested, which produced a weak, statistically not definitely significant, action similar to that described above.

Although it seems most likely that caffeine and theophylline act as real mutagens, as for example nitrogen mustard, the possibility of a selective effect through differential killing has to be considered[3]. A fact that perhaps speaks in favour of this latter interpretation is the distribution of the mutants among the different physiological types, the vitamin-deficiencies (especially inositol-less mutants) being much more numerous than in irradiated or nitrogen mustard treated material[4].

A further elucidation of the phenomenon appears to be desirable for several reasons. Caffeine and theophylline occur in some plants in considerably higher concentrations than those active in our experiments. Of these two substances, at least caffeine interacts, as we have found, in an interesting way in the fungus cell with adenine, one of the chemically closely related amino-purines, which are essential constituents of the nucleo-proteins.

This investigation of the physiological and genetical effects of methyl xanthines, and other purine compounds, is being continued.

Yeast and Rickets

SOME years ago, Brause, Kon and White[1] proved that an addition of high amounts of dried yeast in the ration of pigs produced rachitogenic symptoms. During the feeding practice in our Institute with chickens, we sometimes found that an addition of 2 per cent of dried yeast in the mash (about 1 per cent calculated on the total ration) resulted in a somewhat retarded growth, particularly if the animals did not need the supplement of the B-vitamins provided by this product.

In the light of this experience, we were highly interested in the communication by Hoff-Jørgensen[2], in which he ascribes the unfavourable properties of dried yeast to the presence of a specific phytase-inhibiting substance.

In order to repeat his experiments, we worked with a phytase preparation, made according to the directions of Adler[3]. The splitting of phytin (Ciba) was measured after incubation at 30° C. at pH 5·6 for 1–2 hr., by determining the increase in inorganic phosphorus as well as by direct phytic acid–phosphorus determinations. At the beginning of the incubation periods, 50 ml. of reaction mixture contained 12·5 mgm. of phytin and 12·5 mgm. of the phytase preparation. The splitting was calculated as a percentage of the phytic acid originally present.

The yeast extract was prepared by shaking 4 gm. of dried brewer's yeast with 30 ml. of 0·2 N hydrochloric acid for 2 hr. The centrifugate was brought with dilute sodium hydroxide to pH 5·6 and the volume was made up to 100 ml. 12·5 ml. of this extract (containing approximately 4 mgm. of inorganic phosphorus) was used per 50 ml. of reaction mixture. In addition, determinations were made after adding 4 mgm. of inorganic phosphorus in the form of potassium dihydrogen phosphate.

The results are summarized in the accompanying table.

Percentage splitting of phytic acid after 2 hr. Figures in brackets: after 1 hr.

Buffer	Addition	Splitting (per cent)	
		Calculated from increase in inorganic phosphorus	Calculated from direct phytic acid–phosphorus determinations
Acetate	None	34	66
,,	12·5 ml. yeast extract	20	37
,,	4 mgm. inorganic phosphorus (as KH_2PO_4)	24	39
Citrate	None	38 (23)	87 (47)
,,	12·5 ml. yeast extract	19 (8)	65 (31)
,,	4 mgm. inorganic phosphorus (as KH_2PO_4)	— (10)	65 (32)

As the figures show, we could not confirm the presence of a specific phytase inhibitor in yeast. The inhibition by the yeast extract can be explained fully by taking account of the presence of inorganic phosphorus.

Moreover, it is interesting to note that the results calculated from direct phytic acid determinations are much higher than the results calculated from the inorganic phosphorus determination. This is due to the fact that lower phosphoric acid esters of inositol are not precipitated with the ferric chloride reagent in the circumstances of the McCance and Widdowson method for phytin determination. It shows that the ester bonds in inositol-pentaphosphoric acid, tetraphosphoric acid, etc., are not hydrolysed easier than the first bond which had been split in the phytin molecule.

Most of the experimental work for this investigation was done by Miss M. W. Muÿen. I am indebted to Dr. J. Grashuis for his interest.

USING purified enzyme preparations and certain samples of dried yeast, we have met with the same difficulties as has Dr. de Man in reproducing our first results. We found, however, that the inhibition increased the longer the duration of the experiment, and that the inhibition was considerable when rye bran and dried yeast were incubated together overnight before the adding of the substrate. Experiments show that phosphatases from the bran under these conditions split considerable amounts of inorganic phosphate from phosphoric acid compounds present in yeast. It seems to be this inorganic phosphate which is responsible for our finding of an inhibition of phytase by yeast.

Stimulation of Adventitious Root Formation by Fungal Metabolic Products

IN an attempt to elucidate the contradicting views concerning the nature and properties of *Fusaria* metabolic products responsible for cotton and tomato wilts, certain substances (stimulating for adventitious root formation) have been detected in the fungal filtrates. These experiments have been originally carried out with the aim of testing the two following points.

(1) The response of healthy cotton cut shoots to the metabolic products of either a specific pathogen (*Fusarium vasinfectum*) or a non-specific pathogen (*Fusarium lycopersici*). Two Egyptian varieties of cotton were used for this purpose: one is a wilt-resistant variety, 'Ashmouni', and the other is a susceptible one, 'Giza 26'.

(2) The response of healthy tomato cut shoots to the metabolic products of either a specific pathogen (*Fusarium lycopersici*) or a non-specific pathogen (*Fusarium vasinfectum*). Two varieties of tomato were used, namely, 'Pritchards' and 'North Dakota'.

The filtrate was obtained by growing the fungus in Richard's solution for twenty-eight days at 30° C. The solution was then freed from the fungus, and was passed through a Berkefeld filter. The fungal filtrate was then divided into three portions: (*a*) a portion was kept unheated; (*b*) a portion was boiled for fifteen minutes; (*c*) a third portion was treated with 96 per cent alcohol. A creamy white precipitate is obtained, which is filtered off and dried; an aqueous solution of the precipitate has been prepared. The remaining precipitate-free filtrate has been distilled under vacuum to remove the excess of alcohol, and was afterwards kept for forty-eight hours at 60° C. to remove the last traces of alcohol.

Freshly cut healthy shoots were dipped in either the unheated or the boiled fungal filtrate, in the solution of precipitate, in the precipitate-free filtrate, or in the precipitate plus the precipitate-free filtrate. Control experiments were also made by using fresh Richard's solution and sterilized tap water. The treated cut shoots were left at ordinary laboratory temperature (18–20° C.) and examined at regular intervals.

An interesting phenomenon has been observed when the cotton shoots (of the resistant 'Ashmouni' variety) were placed in the unheated *Fusarium vasinfectum* filtrate; adventitious roots started to appear on the fourth day (Fig. 1). No similar phenomenon has been seen, however, with the susceptible 'Giza 26' variety on any experimental treatment of the fungal filtrates.

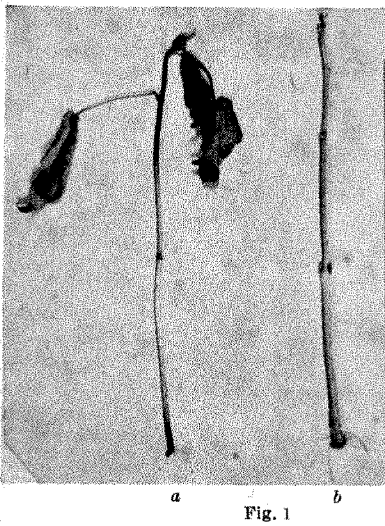

Fig. 1

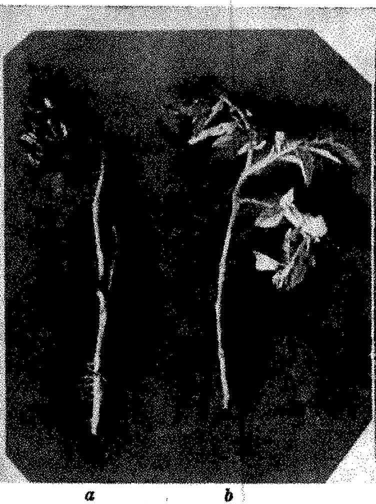

Fig. 2

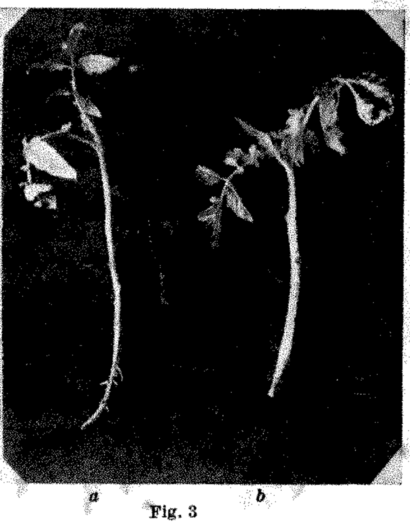

Fig. 3

Fig. 1. Cut shoots of 'Ashmouni' cotton growing on: (*a*) boiled *Fusarium vasinfectum* filtrate, and (*b*) unheated filtrate of the same fungus

Fig. 2. Cut shoots of 'Pritchards' tomato grown in: (*a*) aqueous solution of precipitate from *Fusarium lycopersici* filtrate, and (*b*) pure Richard's solution

Fig. 3. Cut shoots of 'North Dakota' tomato grown in: (*a*) aqueous solution of precipitate from *Fusarium lycopersici* filtrate, and (*b*) pure Richard's solution

Unlike cotton, the adventitious root formation, in the cut shoots of the two experimental tomato varieties, was found to be stimulated as a response to the metabolic activity of either the specific or the non-specific *Fusarium* species; the presence of the active principle—responsible for root stimulation—is only restricted, however, to the solutions of precipitates. Although adventitious root formation was induced in both tomato varieties, yet their development in 'North Dakota' was not so vigorous as that of the 'Pritchards' tomato variety (Figs. 2 and 3).

The fungal metabolic products responsible for root stimulation seem to be thermolabile and filterable through a Berkefeld filter. Further detailed studies concerning the possible nature and detailed properties of these substances are still in progress.

Blood System of the Gut of *Arenicola marina*

During the course of my present investigation into the functional anatomy of the gut of *Arenicola marina*, I have found that Ashworth[1] describes the sub-intestinal blood vessels (sinuses) along part of their length only. He states that these vessels "commence just behind the heart and may be traced to the level of the twelfth setæ, behind which point they disappear". In dissection, with the use of a binocular microscope, it is possible to trace out these vessels, which have been renamed the sub-enteric vessels, along the whole length of the gut. Indeed, they are visible with the naked eye. This observation I believe to be of importance as it shows that the same basic pattern underlies the blood system in all parts of the gut. Serial sections have confirmed this point.

The blood system of the gut of the lugworm appears to be as follows.

The dorsal vessel runs along the dorsal surface of the gut, starting as a network of vessels near the anus and dividing into several branches under the prostomium. Along its entire length this vessel gives off branches to the complicated blood-sinus system lying in the walls of the gut.

The ventral vessel runs underneath the gut beginning as a plexus of vessels surrounding the proboscis and breaking down into a plexus near the anus. This vessel, unlike the dorsal vessel, has no connexion with the blood sinus of the gut.

Four definite longitudinal tracts can be distinguished in the blood plexus in the gut wall: (*a*) two sub-enteric vessels; (*b*) two lateral enteric vessels. The former are very fine and run along the gut from the œsophagus to the anus on either side of the mid-ventral line. The latter are confined to the œsophagus and the front half of the stomach. In segment 7 the lateral enteric vessels are enlarged to form the 'auricles' which pulsate. The enteric vessels communicate on either side with the ventral blood vessel by two thick-walled muscular ventricles.

The four longitudinal tracts are linked to each other and with the dorsal vessel by means of primary transverse tracts, which lie between the rows of pouches in the stomach region. The primary tracts are linked with one another by finer secondary tracts.

The work mentioned here was carried out partly at University College, London, and partly at the Imperial College of Science and Technology, under the supervision of Mr. G. P. Wells, to whom I tender my sincere thanks.

Extrafloral Glands of Cucurbitaceæ

I have already pointed out[1] that quite a good number of species of Cucurbitaceæ are provided with well engineered devices for exudation of surplus water and waste substances. These plants, being primarily moisture loving, have structures especially suited to exudation of aqueous fluids which are absorbed in quantity in excess to the requirement, physiological conditions being very favourable for rapid absorption. The genera *Coccinia*, *Luffa*, *Lagenaria*, *Momordica*, *Cucurbita*, etc., develop extrafloral nectaries. In *Coccinia cordifolia* (Linn.) Cogn. a few glistening glands are present on the lamina round about the basal region of the midrib on the adaxial leaf surface; in *Luffa acutangula* (Linn.) Roxb. and *L. cylindrica* (Linn.) Roem. these glands are often found scattered all over the lamina besides a special fleshy glandular probract being developed at the base of the peduncle of the male and female inflorescences; in *Lagenaria vulgaris* Ser. (*Lagenaria leucantha* (Duch.) Rusby) two bilateral glands are present at the remote end of the petiole and in *Momordica cochinchinensis* (Lour.) Spreng. a few are found at the petiole end or on the lateral marginal costa at the leaf-base; in *Cucurbita pepo* Linn., *C. maxima* Duchesne and *C. moschata* Poiret minute club-shaped glands do develop at the abaxial leaf surface.

The structure of the extrafloral glands is well planned for efficient discharge of waste substances. The essential parts of a gland are the: (1) supply tissue (Figs. 1 and 2, *ST*), (2) filter tissue (Figs. 1 and 2, *FT*), and (3) external excretory tissue or osmotic tissue (Figs. 1 and 2, *ET*). The conducting elements—the vessels and the tracheids—are arranged all round the glands for translocation of catabolic substances in solution to the vital supply tissue. This supply tissue is made of somewhat elongated cells with a distinct nucleus in each cell. As the supply tissue is charged with sufficient fluid, it filters through the single-layered lignified bilaterally thickened

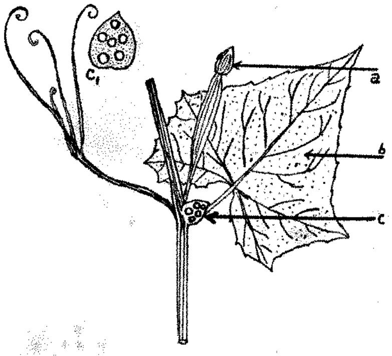

Fig. 1. Portion of a flowering branch of *Luffa acutangula* (L.) Roxb. (*a*) Female flower; (*b*) leaf; (*c*) glandular fleshy probract (× 1); (c_1) probract (× 2)

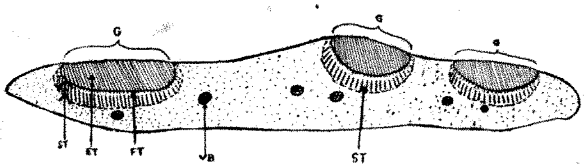

Fig. 2. *Luffa acutangula* (L.) Roxb. Transverse section of a probract passing through three glands (diagrammatic, × 20). *G*, Gland; *V.B.*, vascular bundle; *F.T.*, filter tissue; *E.T.*, external osmotic tissue; *S.T.*, supply tissue

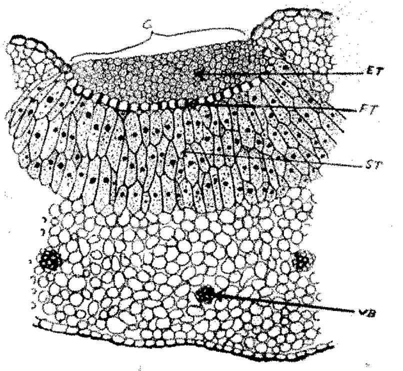

Fig. 3. *Luffa acutangula* (L.) Roxb. Transverse section of a part of the same probract as in Fig. 2. (× 100)
G, Gland; *V.B.*, vascular bundle; *F.T.*, filter tissue; *E.T.*, external osmotic tissue; *S.T.*, supply tissue

filter tissue. An interesting biological significance is attached to this characteristic filter tissue having selective influence on the exudate. Filter tissue guards against the passage of essential nutritive substances through it and permits only waste substances to filter through. The activity of secretion is greatly influenced by the presence of sugar in the secreting cells which acts as osmotic substance. (The sugar is obtained by photosynthesis.) The rate of secretion is also greatly influenced by temperature and sunlight. The secretory activity increases with the rise of temperature and decreases with the fall of it. Most active secretion is marked during the warmer part of the day.

That the extrafloral nectaries are concerned with the vital functions of the plant is evident, due to their presence in the developing organs of the plants. The sugary secretion from the gland also attracts ants and insects and possibly helps in the biology of pollination. Ants are the commoner visitors. They probably perform a defensive function too.

The investigation is in progress, and details will be published in due course.

New Colour and Fluorescence Reactions in the Steroid and Synthetic Œstrogen Series

By using suitable solvents as diluents in the reaction mixture to modify the phosphoric test for natural œstrogens[1], new and apparently specific colour or fluorescence tests have been found for *trans trans* $\Delta^{5:6}$-androstenediol-3 : 17, dienœstrol, 17-ethinyl œstradiol, 17-methyl androstenediol-3 : 17, *d-l*-equilin, œstriol, 16-keto œstradiol, œstrololactone acetate, and Westerfeld's lactone acetate. The use of low temperatures in two of these reactions may be advantageous in the examination of biological extracts. Conditions have been found for the quantitative estimation of androstenediol and dienœstrol. Further work on the quantitative estimation of the other compounds is in progress and will be published elsewhere.

Series A. Natural œstrogens and related phenols. The compound dissolved in 0·2 c.c. glacial acetic acid is mixed with 1·8 c.c. 88 per cent w./w. phosphoric acid, allowed to stand at room temperature for at least one hour prior to dilution with 3 c.c. cold glacial acetic acid. Resulting colours and fluorescence are noted before and after dilution with acetic acid. Some of the results are shown in the accompanying table. Œstriol gives a much more intense green fluorescence if propylene glycol is substituted for acetic acid and the mixture heated at 100° C. for ten minutes. Similar heating with acetic acid instead of propylene glycol gives a mauve-coloured solution with a pale greyish-blue fluorescence in ultra-violet light.

Substance	Colour of fluorescence in ultra-violet light	Comments
Œstrone, equilenin, dihydroequilenin	Green	
α-Œstradiol	Blue-green	
16-keto-œstradiol	Light-green	
3-Hydroxy-16-keto-equilenone	Yellow-green	Oxygen at 17 position is not necessary for fluorescence development
$\Delta^{14:15}$-Hydroxy-16-ketoequilenone	,, ,,	,, ,,
1-Keto 2-methyl 7-hydroxy 1.2.3.4-tetrahydrophenanthrene 2-acetic acid	Light-green	Steroid structure not essential for green fluorescence.
β-Naphthol	Weak-green	,, ,,
α-Naphthol	No appreciable fluorescence	
17-Ethinyl œstradiol	Orange	Fluorescence is rapidly quenched during addition of more acetic acid. A deep pink unstable colour then develops
d-l-Equilin	Pink, with additional acetic acid	Blood-red colour. Stable for many days
Acetate of Westerfeld's lactone	Brilliant green-blue on heating (with additional acetic acid) at 80° C. 5 min.	On addition of the cold acetic acid a pale pink colour developed
Acetate of Jacobsen's œstrololactone	,, ,,	No pink colour was obtained as for Westerfeld's lactone
Stilbœstrol, hexœstrol, *p*-hydroxypropiophenone	No green	
Dienœstrol	Deep blue	Technique of Series B used

Series B. Quantitative procedure for dienœstrol. 25–100 μgm. of dienœstrol dissolved in glacial acetic acid is mixed with 1·8 c.c. 85 per cent phosphoric acid. A sequence of yellow, orange, orange-pink and pink colours develops on standing at room temperature for one hour. Subsequent heating at 100° C. for one hour followed by addition of 3 c.c. of acetic acid and re-heating for a further hour results in the quantitative formation of a bluish-purple colour. An intense violet-blue fluorescence is also given. Hexœstrol, stilbœstrol, hydroxybenzoic acids and pyrocatechol do not give this reaction, but *iso*dienœstrol gives a similar colour. The presence of excessive amounts of *p*-hydroxybenzoic acid interferes with the quantitative determination of dienœstrol.

Series C. Non-phenolic steroids. 25–250 μgm. of androstenediol dissolved in 0·2 c.c. glacial acetic acid is mixed with 1·8 c.c. 85 per cent phosphoric acid, warmed at 55° C. for fifteen minutes, cooled and diluted to 5 c.c. with glacial acetic acid. After standing at room temperature in the dark for seventy-five minutes a violet colour and violet fluorescence (ultra-violet) develops.

This colour reaction appears to be specific for androstenediol and is not given by cholesterol, pregnandiol, cholic acid, 17 ethinyl androstenediol, progesterone, desoxycorticosterone acetate, pregnenolone, $\Delta^{5:6,\ 16:17}$-pregnanedienolone 3 : 20, *trans* testosterone and methyl testosterone. *trans trans* Methylandrostenediol 3 : 17 gives a bright green fluorescence with very little colour, whereas dehydroandrosterone gives an unstable deep pink colour.

Conditions influencing the ease and degree of dehydration of the compounds under test are evidently of considerable importance in the development of colour and fluorescence.

Fermentation of Pyruvate, β-Hydroxybutyrate and of C₄-dicarboxylic Acids by some Butyric Acid-forming Organisms

ACCORDING to several authors, pyruvate is an intermediate in the formation of C_4-compounds in the butanol-acetone fermentation. According to others, pyruvate is not such an intermediate and gives rise only to acetate when fermented by resting cells of butyl organisms. The different results obtained by the various authors can be explained by the utilization of different strains. Thus, we have observed that washed cells of the strain *GR*4 of *Clostridium saccharobutyricum* Schattenfroh and Grassberger, when acting on pyruvate, give rise to acetate and butyrate. The same results are obtained with suspensions of *Cl. acetobutylicum* (Weizmann) McCoy, Fred, Peterson and Hastings, strain *Fd*11, whereas strain *PC*48 and some other strains of the same organism give rise only to acetate when acting on pyruvate. These last strains may need a coupled reaction to ferment pyruvate in the normal C_4-compounds.

M/1,000 arsenite totally suppresses butyric acid formation from pyruvate with those strains able to give both acetate and butyrate from pyruvate[1]. The total volatile acid is about 30 per cent lower in the presence of arsenite than in the controls, but only acetic acid is formed. This suggests a possible transformation of acetate into butyrate during normal fermentation. Such a transformation has been found to occur in cultures in experiments using carbon-13 by Wood, Brown and Werkman[2]. Further experimental evidence for this fact has been adduced by us on the course of pyruvate fermentation by resting cells. At the beginning of the experiment, pure acetic acid was obtained, while the ratio butyric/acetic acid eventually reached 1/1 and even 2/1 (Duclaux distillation data).

Acetate alone, or in the presence of hydrogen (with and without phenosafranine), does not give rise to butyrate.

Peldàn[3] suggested that β-hydroxybutyrate could be an intermediate in the formation of butyric acid. We have found that this compound is readily fermented at *p*H 7 by washed suspensions of all the strains of *Cl. saccharobutyricum* and *Cl. acetobutylicum* tested, whether or not they were able to form butyrate from pyruvate. The volatile acid products of this fermentation were acetic and butyric acids in the ratio 1/1, independently of the time of incubation. Butyrate formation from β-hydroxybutyrate is unaffected by arsenite. Our results on β-hydroxybutyrate fermentation do not agree with the conclusions drawn by Johnson, Peterson and Fred[4] from their studies on growing cultures.

Our strains, in accordance with the findings of Simon and Weizmann[5], do not ferment succinate. On the contrary, fumarate, oxalacetate, and to a lesser extent, malate, are well fermented to butyric and acetic acid by *Cl. saccharobutyricum* (strain *GR*4).

We propose as a working hypothesis the following scheme for butyric acid formation:

pyruvate → acetate → unknown intermediates → β-hydroxybutyrate → acetate + butyrate.

According to this hypothesis, arsenite acts on a stage anterior to the formation of β-hydroxybutyrate.

A detailed account of the experiments will shortly be published elsewhere.

British Abstracts

IN my section of the account published in *Nature* of August 21 of the Royal Society Scientific Information Conference, I stated that ***British Abstracts*** were of the 'indicative', that is, a briefer type; other abstracts were of the 'informative', that is, a longer type. That is how those various services describe the abstracts they publish. Fear has been expressed lest those unfamiliar with *British Abstracts* or with the use of these words, 'indicative' and 'informative', in this connexion may infer that *British Abstracts* differ radically from all the others, and may be even merely extended titles. This, of course, is not so.

The papers circulated to the Conference explained that an 'indicative' abstract aims at giving the reader sufficient information to decide whether he should read the original paper or not, and that while the 'informative' abstract is usually longer and contains more data, many of the abstracts published by the 'informative' services are of the 'indicative' type.

I am left with some doubt, however, regarding the aptness and usefulness of these words in this connexion.

DAVID CHADWICK

HEXOSAMINE COMPONENTS OF THE HUMAN BLOOD GROUP SUBSTANCES

By D. AMINOFF and W. T. J. MORGAN

Lister Institute of Preventive Medicine, London, S.W.1

FOR some time past we have been engaged on the isolation and characterization of the specific blood group substances which belong to the *ABO*[1] system. The identification of the component molecules of these complex mucoids has been delayed until satisfactory evidence for the homogeneity of the substances was obtained. On the basis of the results of measurements which have involved the physical, chemical and immunological properties of the human group *A*-substance, we consider that this material has now been obtained as a homogeneous complex. Full details of its preparation and properties will be given elsewhere[2].

The partial and complete hydrolysis products of the homogeneous *A*-substance have been investigated, and during the examination of the amino-acid components by means of two-dimensional paper partition chromatography[3], using collidine and phenol-ammonia as solvents, it was observed that two of the thirteen spots which developed on treatment of the paper with ninhydrin could not be identified with those expected from known amino-acids. It is well known, however, that the hexosamines, glucosamine and chondrosamine, of which glucosamine has already been identified as a component of the *A*-substance, react with ninhydrin under the conditions of the test to give a greyish-mauve area indistinguishable from the coloured areas which arise from the majority of amino-acids.

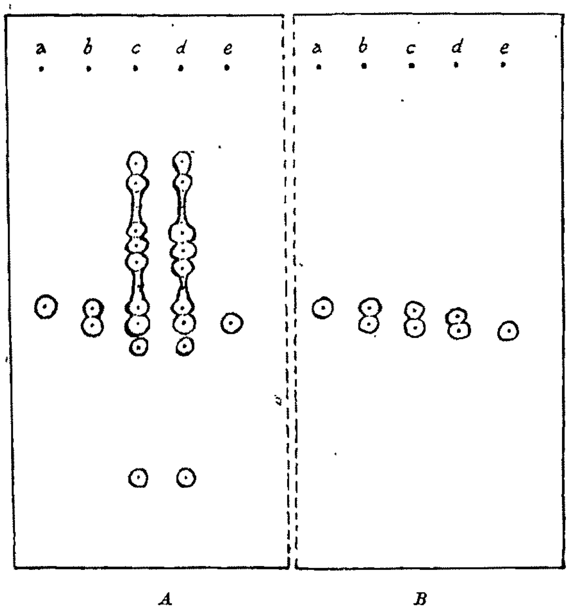
The colour reaction of the amino-sugars, glucosamine and chondrosamine, with a modified Ehrlich's reagent after treatment with an alkaline solution of acetylacetone under carefully controlled conditions has been used for the quantitative determination of these hexosamines[4], and has recently been extended to their detection in paper chromatography[5]. Using this reagent with the *A* hydrolysis products, two cherry-red spots were obtained corresponding in position to the two unknown ninhydrin spots.

A two-dimensional paper chromatogram using collidine and phenol-ammonia (0·6 per cent w./v. ammonia and coal gas) as solvent systems on the hydrolysis products (1 mgm.) of *A*-substance (16 hr. 6 *N* hydrochloric acid at 100°), to which 0·1 mgm. each of glucosamine and chondrosamine hydrochloride were added, resulted in no additional spots appearing when the paper was developed with ninhydrin. A similar chromatogram produced simultaneously with glucosamine (0·1 mgm.) and chondrosamine (0·1 mgm.), but developed with the hexosamine reagents in place of ninhydrin, revealed two areas corresponding in position to the two unidentified ninhydrin spots. It seemed probable, therefore, that the two unidentified ninhydrin spots were due to glucosamine *and* chondrosamine.

Two additional chromatograms using the acid hydrolysis products of the human *A*-substance were run with (*a*) collidine and *n*-butanol-ammonia (3 per cent w./v. ammonia) and (*b*) collidine and *n*-butanol-water as solvents. Both chromatograms showed two ninhydrin spots which, however, were not due to methionine or tyrosine, which have the same R_F value in these solvents, because two similarly placed cherry-red spots were obtained on another sheet run simultaneously and sprayed with the hexosamine reagents. The separation of the two hexosamines in butanol is poor; but with butanol-ammonia and with collidine a useful resolution is obtained.

These observations were correlated by making a run with collidine as solvent on a single sheet of Whatman No. 1 paper. Along the width of the paper, ten positions were marked out and the following substances (or mixtures) were put on the paper and run with the solvent for 72 hr.: (*a*) chondrosamine hydrochloride, (*b*) chondrosamine and glucosamine hydrochlorides, (*c*) acid hydrolysis products of *A*-substance with (*b*) added, (*d*) acid hydrolysis products of *A*-substance alone, and (*e*) glucosamine hydrochloride. The series was repeated on the remaining half of the paper. The paper was then dried and cut into two along the dotted line (see figure); one half was sprayed with the ninhydrin reagent and the other half with the hexosamine reagents. The coloured areas which developed are shown diagrammatically. There seemed strong evidence for believing that both amino-sugars were present as components of the *A*-complex.

N-acetylglucosamine and N-acetylchondrosamine give no colour with the ninhydrin reagent, move faster than the corresponding bases and yield a mauvish-pink colour with the hexosamine reagents. N-methyl-L-glucosamine, a component of streptomycin[6], has an R_F value in collidine only slightly greater than glucosamine, but its colour reaction with ninhydrin—a pale pink colour forming after heating at 80–90° for a few minutes—is in marked contrast to that shown by glucosamine and chondrosamine and by the 'unidentified' spots which arise from the hydrolysis products of the group *A*-substance. Again, under the test conditions with the hexosamine reagents, N-methyl-L-glucosamine develops a mauvish-pink colour, reminiscent of coloration which arises from the acetylhexosamines and very different from the cherry-red colour given by the hexosamines.



A. Chromatogram developed with ninhydrin reagent.

B. ,, ,, ,, acetylacetone followed by Ehrlich's reagent

It has been observed that treatment of the paper with collidine or phenol, but not butanol, seems to suppress its reaction with the ninhydrin and hexosamine reagents. Thus, although the chromatographic data do not completely rule out the possibility of the presence of N-methyl-L-glucosamine, this substance is certainly not responsible for either of the hexosamine spots obtained.

Partridge[5] examined by the chromatographic technique the sugar components of an inhomogeneous preparation of *A*-substance obtained from gastric mucin[7] and concluded that chondrosamine was not present.

To summarize the evidence for the occurrence of glucosamine and chondrosamine in the group *A*-substance, it may be stated that as a result of examining the complete acid hydrolysis products of the substance on paper chromatograms, two spots which occur close together are detected with three different reagents: (*a*) ninhydrin, (*b*) ammoniacal silver nitrate[5] and (*c*) the hexosamine reagents. All three reagents detect the hexosamines but under the test conditions exclude the presence of the N-acetyl derivatives and N-methyl-L-glucosamine. The two spots have R_F values identical with glucosamine and chondrosamine in (*a*) collidine, (*b*) phenol-ammonia, (*c*) *n*-butanol, and (*d*) *n*-butanol-ammonia (3 per cent w./v.). The addition of glucosamine and chondrosamine to the hydrolysis products of *A*-substance results in the development of no additional spots irrespective of the reagents used for development. Treatment with zeolite resulted in the removal of glucosamine and the unknown material[7] as determined by ammonia – silver nitrate reagent. Fractional precipitation of the *A* hydrolysis products with acetone and ether results in the separation of material which when tested on paper strips gives rise to two spots which are considered to be due to the presence of glucosamine and chondrosamine.

Preparations of the *A*- and *H*-substance[8] (the so-called '*O*' substance) obtained from pig gastric mucin, and partially purified *H*-substance isolated from human pseudo-mucinous cyst fluids, also show the presence of the two hexosamine spots.

An examination of the relevant literature shows that in many instances the amount of glucosamine isolated from the hydrolysis products of mucopolysaccharides and mucoids represents only a small part of the total hexosamine estimated to be present by the colorimetric method. For example, Meyer, Smyth and Palmer[9] isolated about 30 per cent of the total hexosamine present in a preparation of the neutral polysaccharide of pig's gastric mucosa, whereas from the acid mucopolysaccharide coexisting in this tissue a yield of more than 90 per cent of the hexosamine present was obtained. Several procedures have been devised for the isolation of glucosamine which give excellent yields of this amino-sugar[10], but in spite of the application of these methods to the hydrolysis products of some mucopolysaccharides poor yields of glucosamine have been obtained. In view of the difficulty of isolating chondrosamine, however, it is suggested that in certain instances the poor yields of isolated glucosamine might well be due to the presence of a second amino-sugar, and a re-examination of the nature and amount of the 'hexosamine' component in these materials is suggested.

The identity of the second hexosamine present in the blood group substances with chondrosamine is not conclusively established by the evidence presented in this communication, and the claim that it is a component must await the isolation of one or more crystalline derivatives identical with the corresponding derivatives of an authentic specimen of chondrosamine. We are now engaged on obtaining this evidence.

We are indebted to Prof. M. L. Wolfrom for a sample of N-methyl-L-glucosamine.

VOLATILE CUPROUS AND SILVER SALTS OF FATTY ACIDS

By A. KELLER

Department for General Chemistry, University of Budapest

AND

DR. F. KÖRÖSY

Vavil Research Laboratory, Vacuumtechnical and Electric Co., Budapest

IN a communication in *Nature*[1], one of us (F. K.) reported on a volatile copper compound obtained by thermal decomposition of cupriformate. J. G. Maltby[2] directed attention to the work of A. Angel and A. V. Harcourt[3], according to whom cuprous acetate forms as a white sublimate when cupriacetate is heated.

We succeeded in isolating the volatile product of decomposition of cupriformate, and microanalytical determinations proved that it was cuprous formate. Our previous assumption that the 'volatile' compound was present in the form of vapour or gas in the gas streaming over the decomposing cupriformate was erroneous. Passage of the gas through layers of 5–30 mm. length of cotton wool, glass wool or asbestos revealed that we had been dealing with an extremely fine aerosol which could be 'developed' by chemical methods along the stopping layer, for example, with hydrogen sulphide as brown-black cuprous sulphide. The distribution of colour along the layer gave the impression of decreasing exponentially along its length. The aerosol also acted on saturated vapours, forming condensation centres.

By causing turbulent flow of the transporting gas, for example, by blowing it against a wall or into a reversed capillary, we obtained a white deposit of this aerosol which showed the following reactions: (1) water or water vapour decomposed it into a yellow solid (cuprous hydroxide) and formic acid; (2) acids decomposed it into a red insoluble powder of metallic copper and blue cupriformate; (3) it sublimes *in vacuo* between 100° and 105° C. but begins to decompose already at 105° C. (this may account for the fact that Kohlschütter[4] failed to detect it in his detailed work on cupriformate decomposition, because he worked at about 200° C.); (4) because it is decomposed by water and acids (1 and 2), it was difficult to collect sufficient pure material for analysis, since water and formic acid are among the primary decomposition products of the cupriformate. The gas had to be dried with calcium chloride and neutralized with layers of potassium carbonate which occluded most of the aerosol. However, it was possible with extreme precautions to prepare samples of 3–8 mgm. and to determine iodometrically their copper content and bromometrically their formate content, after having duly identified the latter by the calomel and silver reduction methods. Naturally, Cu and $HCOO^-$ were separated from each other before determination. The results agreed within 2–4 per cent with the theoretical values for cuprous formate (CuHCOO).

The only mention of this substance in the literature is to be found in A. Angel's paper[5], who obtained it from solution. We found that the formation of white cuprous compounds which sublime is a general property of cupric fatty acid salts: the acetate, propionate, valerate behaved in a similar manner; laurate and stearate, though melting and carbonizing, yielded mirrors also, indicating a similar decomposition of these salts as well. The cuprous compounds were all very prone to thermal decomposition into metallic copper. They also reacted with water and acids like the formate (reactions 1 and 2):

$$Cu.HCOO + H_2O \rightarrow CuOH + HCOOH \tag{1}$$

$$2Cu.HCOO \xrightarrow{H^{\cdot}} Cu(HCOO)_2 + Cu. \tag{2}$$

An old Liebig combustion tube, when heated gently while a stream of nitrogen passed through it, showed copper mirror formation at several points and a white deposit was formed at the end of the tube, where the temperature was about 100° C. The latter looked like cuprous formate and gave all its characteristic reactions. This fact seems to explain former observations on volatile copper in combustion tubes, which originally contained no fatty acids, though traces of other organic compounds were present, of which fatty acids—most probably formic acid—might arise through heating by the catalytic action of copper.

We also prepared the fatty acid salts of silver, taking care to avoid decomposition of the formate by immediate washing of the precipitate. The formate explodes with intense detonation on heating to 90–100° C.; it was necessary to mix it with indifferent powders to avoid detonation. All these salts could be made to sublime *in vacuo* using a micro-technique with extreme precaution. The analogy with the cuprous compounds seems to be perfect. Some tentative experiments with gold hydroxide in a stream of warm formic acid vapour looked as if there had been miniature explosions and mirror formation; however, we do not wish to insist upon the reality of these observations.

The analogy of silver and cuprous formate gave us the key to the quantitative study of thermal decomposition of the copper formates. First of all, we determined the gas reaction products of the decomposition of silver formate and found that it agrees with the following reaction:

$$2Ag.HCOO \rightarrow H_2 + 2CO_2 + 2Ag$$

within about 5 per cent, of which 1 per cent was methane, somewhat less carbon monoxide and the rest unidentified. Traces of water could also be observed. We assume that cuprous formate, which could not be prepared in a quantity sufficient to study this reaction, decomposes in the same manner.

On the other hand, we determined the decomposition products of 1 mol. of the thermally decomposed cupriformate, and found as average a relative error of about 5 per cent for carbon dioxide and formic acid and an error of 10–15 per cent for the rest:

0·97 mol. per cent carbon dioxide
0·84 mol. per cent formic acid
0·10 mol. per cent hydrogen
0·08 mol. per cent water (approximately)
0·05 mol. per cent carbon monoxide ,,

This accounts for 102 per cent hydrogen, 93 per cent carbon and 94 per cent oxygen. The results indicate clearly that the main line of decomposition (say, 80 per cent) must follow the reaction:

$$Cu(HCOO)_2 \rightarrow Cu + HCOOH + CO_2.$$

Only a side branch of the decomposition can go through cuprous formate if we assume that (1) its decomposition is analogous to that of silver formate, and (2) all hydrogen found is formed from this cuprous salt:

$$2CuHCOO \rightarrow 2Cu + H_2 + 2CO_2.$$

In this case the excess of carbon dioxide with respect to formic acid should be double the molecular percentage of hydrogen, while actually 1·3 mol. were found; but the experimental errors may account for the difference. Roughly, 15 per cent of the original cupriformate would have reacted in this event to yield cuprous formate, and it can be stated with reasonable certainty that the reaction taking place is:

$$2Cu(HCOO)_2 \rightarrow 2CuHCOO + HCOOH + CO_2.$$

There is, however, a possibility of the following reaction:

$$2Cu(HCOO)_2 \rightarrow 2CuHCOO + H_2O + CO + CO_2.$$

The presence of carbon monoxide and water could be taken as indication of the second reaction, but the fact that the carbon monoxide obtained was approximately half the hydrogen found may indicate that it is only one of several reactions occurring. We should not forget that Kohlschütter found a small quantity of hydrocarbons among the decomposition products; this may have been synthesized by catalytic action of the highly disperse copper from the primary products. We found only insignificant traces of formaldehyde among them.

On the hypothesis that the direct decomposition of cupriformate yields copper powder and that decomposition through intermediary cuprous formate is responsible for the formation of the copper mirror on the wall of the reaction vessel, we tried to separate these two forms of copper and found that there is certainly not more than 25 per cent copper in the form of the mirror. It may have been considerably less, in accordance with the above calculation.

The nature of the 'volatile copper compound', or more correctly 'compounds', is therefore definitely established, and the main lines of thermal decomposition of cupri-, cuprous and silver formate are determined with reasonable certainty.

A detailed account of the work will appear in *Magyar Technika.*

ENGINEERING STUDENTS AND MATHEMATICS

On the morning of September 14, at a joint session of Sections A (Mathematics) and G (Engineering) of the British Association, a discussion took place upon the subject of "Applicable Mathematics".

Wing-Commander T. R. Cave-Browne-Cave (president of Section G) in his opening remarks emphasized that mathematics is a matter of importance, but often of difficulty, to engineering students.

Mr. D. N. de G. Allen (Mathematics, Imperial College of Science and Technology, London) said he spoke as one engaged in teaching mathematics mainly to undergraduate and postgraduate engineering students. He would consider not the oft-asked question: "What does the engineer require of mathematics ?", but rather "What does his mathematics require of the would-be engineer ?" Mathematics is an integral part of engineering science, evolved to satisfy the demands of engineering, and should be used by the engineer as one of the tools of his trade. The obstacles the engineer has to overcome are: first, the fact that his problem is stated in engineering terms, and must at the outset be translated into mathematical terms; secondly, the mathematical problem must be set up; thirdly, a mathematical solution must be found; fourthly, this solution must be translated back into an engineering solution. In stage one it is desirable that *all* the available data be explicitly stated. In stage two it is especially important to realize whether the mathematical problem is, or is not, complete in itself. In stage three the maximum possible use should be made of simple ideas, simple methods, and simple functions. In particular, numerical methods, which enable formerly intractable problems to be solved by simple arithmetic, using processes which are intelligible at every step, have great merit, at postgraduate as well as at undergraduate level. At the same time, however, the more advanced mathematical methods should not be entirely overlooked; the engineer should be aware of the existence of such methods, and should know when, and how, to consult the mathematical expert.

Dr. J. A. Pope (Engineering, University of Sheffield) pointed out that engineering, a branch of applied science the object of which is to create objects of immediate utility, calls upon many branches of science; and while the engineer could not be expected to have a detailed knowledge of all these branches, he must know enough to be able to appreciate the significance of the information supplied by the specialist. But engineering is also a delicate balance between tradition and the application of scientific knowledge, the 'factor of safety' representing the traditional element in design. Turning to mathematics, he suggested that any mathematical process which the engineer is prepared to adopt must be susceptible of a physical interpretation, and this, indeed, at every stage. Another necessity for the engineer is 'pictorial vision', and this can be both aided and exploited by copious use of graphical methods in teaching mathematics; abstract ideas can with advantage be handled by means of graphical representation, for example, vector diagrams, and the Argard diagram for complex quantities involving $i = \sqrt{(-1)}$. After brief reference to some essential elements, such as power and Fourier series, integration, partial differentiation, and differential equations, the advantages of numerical methods (step-by-step and 'relaxation') were mentioned, and the necessity of some more advanced mathematics for the abler men was pointed out. But there is a difference in intellectual make-up between the mathematician, master of abstract thought, and the engineer, servant of practical necessity. This has sometimes led to barbarous treatment of mathematical lecturers by otherwise well-behaved engineering students, and to a 'pearls before swine' attitude on the part of some of the former.

Mr. F. S. Snow (president, Institution of Structural Engineers)—whose contribution was read for him on account of illness—referred more particularly to the extent to which the average engineer needs to utilize mathematics in the solution of day-to-day problems. The more experienced an engineer, the less mathematics he personally uses in his day-to-day business. He is, however, able to use the mathematics he learned as a student when necessary, and knows where to turn for the more advanced methods. But the experienced engineer will not profess to be able to design, say, a reinforced concrete column by eye alone, and he will employ younger engineers, and perhaps even mathematicians, to perform the calculations inseparably connected with design. For these, familiarity with mathematics, at least as far as the calculus, is essential. From time to time, new theories based on new assumptions are produced, usually by the mathematicians, and at first the engineer must rely upon the resulting formula; reinforced concrete shell roofs are an example. On the other hand, the practical engineer is faced with uncertainty as to data, as to the properties of many of the materials he uses, and as to the excellence (or otherwise) of the workmanship. Mathematically elegant designs may be scrapped because they demand a higher standard of workmanship than is generally available. Thus, while all engineers should attain a standard in mathematics at least as high as that prescribed by the professional institutions, they require also to amass a vast amount of experience.

Dr. A. G. MacFarlane (Telecommunications Research Establishment, Malvern) devoted himself to a particular, rather than a general, aspect of the subject under discussion, namely, the calculus of variations and its usefulness as a method for the solution of physical and engineering problems. He referred to the development of the principle at the end of the eighteenth and beginning of the nineteenth centuries as outstanding, the most important feature being Hamilton's demonstration that the equations of dynamics might be derived from a stationary principle. As a result, variational principles now occupy a central position in theoretical physics, but are still not used as much as they might be. Most problems must be idealized before they become tractable, but the more powerful the mathematical technique, the less the amount of idealization necessary; it is therefore desirable to review all the possible methods when tackling any problem. Most physical problems are usually stated mathematically in terms of differential equations and boundary conditions. But differential equations are 'local', and use of integrals is advantageous, because they include the behaviour of the functions over the whole range of variables, and also because they incorporate the boundary conditions. Such methods are (1) integral equations, (2) variational principles. Using for illustration the diffraction of electromagnetic waves by a slit, the advantages of the variational methods were outlined. The variational equations may be solved, for example, by Ritz's method or by 'relaxation'. Another advantage is that the integral which is to be made stationary usually represents a quantity of great physical significance.

Prof. W. G. Bickley (Mathematics, Imperial College of Science and Technology, London) said that the opening speakers had considered the mathematical education of the ordinary engineer, and the mathematical needs of the extraordinary engineer, in what seemed to him about the right proportion, and had underlined the fact that the problem exists at two levels. At the lower level the problem is not so much *what* to teach, as *how* (and to some extent *when*) to teach it. Following up Mr. Allen's emphasis upon the necessity of translating from the language of engineering to the language of mathematics, he stressed the desirability of the lecturer in mathematics being able to speak the engineer's language. One of the greatest obstacles in the way of the enlightened mathematician is the still too prevalent attitude that mathematics should be avoided like a plague, instead of used to increase efficiency. It is inconsistent to advocate modern machine tools in the workshop, and fall back upon the equivalent of cold chisel and file for thinking. So absurd, indeed, that he wondered whether the mathematicians had always given the engineering students a fair deal, whether the barbarity referred to by Dr. Pope was partly their fault—if there was a 'pearls before swine' attitude, then barbarity was just retribution. Speaking of engineering students as amenable to sympathetic treatment, and of teaching them mathematics as a rewarding and enjoyable task, he urged his mathematical colleagues to take this task seriously. Familiarity with the mathematical chapters of the engineering text-books would give much food for thought, in more ways than one. Improvements were, of course, being made, and he instanced the work of a sub-committee set up by the Mathematical Association. But education is a slow process. Perhaps some of his students, becoming lecturers in engineering, might condition the minds of their students to more and better mathematics.

Turning to the high-level problem, Prof. Bickley said two things are necessary—to be able to give a 'top-dressing' of applicability to the graduate mathematician, and a top-dressing of mathematics to the abler graduate engineer. For this a central "Institute for Applicable Mathematics" is desirable. Attached to a university, but maintaining close contact with research institutions, with a staff collectively conversant with classical and modern mathematics, mathematical physics and technology, interested in seeing where and how mathematics has aided and can aid the scientific worker and technologist, such an institute would so equip its students that they might fit very quickly into any research institution or could become teachers in the technical colleges and universities. Part-time and refresher courses, for those already engaged in research or teaching, would also be provided. Indeed, the principle had been agreed, but lack of funds has prevented a start being made. Could industry, perhaps on a co-operative basis, come to the rescue? If so, the outlay would earn rich, if perhaps indirect, dividends.

Sir Richard Southwell remarked upon the friendliness of the discussion. He thought this a good thing, because in his opinion there *is* a fundamental difference of outlook between mathematician and engineer, in consequence of which they would have to agree to differ—and agreement to differ is possible only between friends. He gave some illustrations of the difference of outlook. As regards calculus of variations, he thought that many engineers were already familiar with examples of the idea, for example, minimum strain energy as a basis for analysis of structures. Many abstract ideas could be assimilated if they were approached through concrete examples, and he agreed with Dr. Pope's emphasis upon keeping the physical meanings in view. He also instanced Rayleigh's use of variational methods for deducing governing equations throughout his great "Theory of Sound".

Mr. R. A. Fairthorne agreed upon the necessity of properly stating the problem. To do this needs a realization of what is essential, and he had found lawyers and journalists, who habitually have to endeavour to see the essence of a problem they do not understand, better at this than mathematicians or engineers. Training in logic or philosophy greatly assists. Prof. H. S. Ruse commented upon the general keenness of engineering students. He suggested that what was perhaps more important to the engineering student than acquisition of technique was an appreciation of mathematical methods of thinking. Prof. S. J. Davies said that what he would wish for his students was that the mathematicians would teach them mathematics. He mentioned that a water turbine recently constructed according to the 200-year-old design of the mathematician Euler had an efficiency of more than 60 per cent.

Prof. Bickley thought that Sir Richard Southwell tended to exaggerate the difference between mathematicians and engineers; but that so far as it did exist, a friendly agreement to differ, along with a sincere attempt to understand one another's language, were desirable. He agreed with Mr. Fairthorne upon the importance of being able to discern the crux of any problem, and thought that the conciseness and precision of mathematical expression were a great help in this direction. He was glad that Prof. Ruse could agree about the keenness of engineering students. He could agree with Prof. Davies, and asserted that the one thing that the mathematics course should not appear to be was a sequence of *ad hoc* tricks for doing particular jobs. He did, however, think that the best chance of getting engineering students to appreciate mathematics for its own sake was to start with a recognition and an understanding of their interests and habits of thought.

CONTROL OF ENVIRONMENT IN HORTICULTURE

ON September 13, Section M (Agriculture) of the British Association held a discussion on "Control of Environment in Horticulture", over which Prof. H. D. Kay presided.

Dr. W. F. Bewley opened with a paper on "The Control of Heat and Light in Glasshouses". He pointed out that although plants in glasshouses are warmer and more sheltered than those in the open, the light intensity is reduced, moisture tends to accumulate, and crop rotation is scarcely possible. So the owner of glasshouses has problems to face which have no parallel in field cultivation.

The action of light must be considered in two different ways, namely, its photosynthetic effect on the production of carbohydrates with the consequent increase in growth, and its photoperiodic effect in deciding the actual time of flowering. Dealing with the former and referring to workers in the United States, Holland and Britain, he pointed out that by irradiating seedlings and young plants for three or four hours at the end of the day, it is possible to stimulate growth considerably, and in the case of cucumbers to achieve a worthwhile increase in crop. The main facts emerging from the experiments are that a high light intensity, 300–400 foot candles, is necessary, that the effect is mainly upon young plants and that the cost of the apparatus is high. The work has not yet reached a stage at which it could be recommended to commercial growers.

In photoperiodism, the case is much different, for by adjusting the length of day either by darkening or irradiating the plants, it is possible to retard or advance the flowering of many plants; and in the case of chrysanthemums to produce flowers for market at any time of the year. The apparatus is cheap, the duration of illumination short, and the process effective. He suggested that the assistance of physicists and engineers is necessary to solve the problem of light supply to increase growth and crop production, and that large-scale illumination from high-power lamps above the ranges of glasshouses might provide the solution. Until this is achieved, growers should site their nurseries in districts where winter light is at a maximum, glasshouse builders should design better lighted houses, and east-to-west houses should be built for propagating young plants and for growing pot plants during the winter.

Turning to the question of heat, Dr. Bewley said that considerable progress has already been made in thermostatic control. It is now possible to maintain a constant night temperature by applying thermostatic control to all systems of heating, including high- and low-pressure steam, steam-cum-water, oil-fired boilers, gravity feed and under-feed stokers using solid fuel. Despite these improvements, however, he said little has been done to cool the glasshouses during the summer, and he hoped the engineers would help.

On the subject of soil warming, he discussed the relative values of electrically heated wires and hot water circulated through small pipes. Soil-warming experiments have shown that raising the soil temperature provides bigger and cleaner roots, better plants, heavier crops and earlier maturity.

In conclusion, Dr. Bewley concluded that temperature control of glasshouses has already made good progress, but that control of light is still a problem for the future.

Mr. Raymond Bush, who followed with a paper on "Frost and the Fruitgrower", said that prior to 1935 no real attention had been given in Britain to May frosts. Indeed, the East Malling conference held that year showed very clearly that no one knew very much about them. From his extensive investigations, Mr. Bush gave many examples of frost injury which showed very clearly that cold air follows to some extent the behaviour of water in flowing over the land; it follows the contours, settling in valleys and hollows generally, or draining through them without causing damage. In view of the way in which great variations in crop production can be attributed to frost, he urged the necessity for selecting the correct site when planning new plantations, and expressed the view that areas of land suitable for future development should be earmarked for this purpose. So many orchards, however, are so badly sited that it is now a question of fighting the frosts and not preventing them. In this respect Mr. Bush discussed the value of shelter belts, but pointed out that they should contain gaps through which the cold air could drain away to levels below the orchards.

The talk was admirably illustrated with lantern slides. By this means, Mr. Bush gave a clear picture of the present attempts to fight frosts both in America and in Great Britain. He discussed the use of heater pots, the movement of air by mechanical means, including the helicopter, and the use of smoke generators and infra-red lamps. In conclusion, he was careful to point out that the wise choice of a site is still of fundamental importance.

The last paper, by Mr. F. A. Secrett, was on "Horticultural Crops in their Relationship to Water". Mr. Secrett said that the present world food shortage demands that the best use must be made of all available land, and that if the weight per acre could be increased, more land would be freed for other crops. He argued that as the growth of plants varies directly in accordance with the water supply, we experience gluts in wet weather and shortages in dry weather. Further, dry spells in the summer cause delay in sowing or planting the second crop. Armed with an efficient irrigation plant, growers are independent of rain. They can produce better crops of higher quality vegetables and continue their cropping programme unhindered by dry weather. Indeed, he claimed that some crops can be doubled in weight where watered overhead, especially if a little soluble nitrogen is added to the water.

Mr. Secrett discussed in detail the results of experiments on his farm carried out in co-operation with Rothamsted Experimental Station. For example, the application of 4 in. of water increased the yield of carrots by 20 per cent. Sugar beet producing 20 tons of roots in the control plot gave 29 tons in plots receiving 10 in. of water by overhead irrigation, and in addition to this the sugar content was increased considerably. Speaking on the question of quality, Mr. Secrett claimed that when vegetables are irrigated correctly they improve in flavour, and gave examples of this in the case of radish, lettuce and cauliflower. Overhead irrigation is a very valuable process in the hands of the grower.

The advantages of overhead irrigation are many. The grower is independent of rain, and can continue to carry out his crop programme and cultivations in the driest weather. Quality is improved, weight of crop per acre is increased, a high plant population is possible, and pests due to drought are controlled. Soluble fertilizers can be added to the water and minor elements also supplied in this way. Production is speeded up and a greater variety of vegetables can be grown.

The discussion was opened by Lord Bledisloe, who was followed by Sir John Russell and others. In replying to questions Dr. Bewley said that, whereas glasshouse growers as a whole are not attracted by cloches, new entrants into horticulture are learning how to use them and many seem satisfied with the results. He thought that no objection could be raised to steel houses on the basis of more severe temperature fluctuations. He had examined most glass-substitute materials, and while some are satisfactory for a year or two, those that are cheap enough for commercial purposes do not stand up to weather conditions very long. He had long been interested in waste heat from power stations and factories. Usually the waste hot water is not hot enough for circulating in the glasshouse pipes, and there is the disadvantage of injurious fumes and grit owing to the close proximity of the industrial plant.

Mr. Bush, in reply to questions, emphasized that shelter belts should always contain gaps through which the cold air can drain away. The lime makes a good shelter belt, but must not be too dense.

Mr. Secrett said that the addition of nitrate of potash in the irrigation water had always given better results than nitrate of soda, but he could not say why. It was perhaps surprising that the very small amounts of fertilizers used in the water had such big effects, but it was probably due to the repeated applications. There is no limit to the area that can be irrigated provided the spray lines are available. His units are four acres, and at Milford he irrigated twenty acres from one centre.

INTER-UNIVERSITY RELATIONS AND EXCHANGES

THE question of inter-university relations, which was discussed on July 21 at the Congress of Universities of the Commonwealth, is partly an administrative and partly an academic question. On one hand, it is necessary to make such business arrangements between the universities as will enable a young student or teacher to move from one university to another without academic loss of standing or financial embarrassment. On the other, it is necessary to make such an exchange sufficiently attractive from an academic point of view for the man or woman contemplating a temporary migration to make sure that it will be academically advantageous. No young man with academic ambitions —which will probably be centred in his own country— will welcome the idea of an exchange which will leave him for a year in a university which is not equipped whether in its libraries or laboratories to enable him to develop his own research. Conversely, no university will welcome a teacher who regards himself as nobly and self-sacrificingly spreading the joys of learning to universities less lucky than his own.

This latter problem can only be met by the universities knowing each other better. Though many of the speakers at the Congress admitted that their universities were ill-equipped for certain types of work, almost all were able to claim that in one subject or another they were doing work, or had work waiting to be done, which would be most attractive to a young teacher anxious to become master of some topic. The vast quantity of work awaiting the historian of Australia is an example. The first essential is that the universities should know each other far more intimately than they do at present. The Congress agreed to recommend that the universities of each country should be encouraged to form an agency which should act as an instrument of communication with universities elsewhere. Further, since the whole Congress meets only every five years, it was suggested that, in the years between such meetings, vice-chancellors and senior members of staff should visit each other as frequently and as regularly as possible.

The Congress passed several resolutions designed to make the traffic between universities easier and less hazardous. The first resolution dealt with the announcement and advertising of vacancies. It is in this stage that the central office of the Universities Bureau can be of great assistance. It can keep in touch with the appointments committees of the several universities and provide information about the type of post to be filled. It can arrange for candidates to be interviewed by a panel composed both of experts in any subject and of men acquainted with the university which is advertising a vacancy. It can arrange for the successful candidate to be given expert advice about what he may expect to find at the university to which he is going. But it cannot fulfil these functions unless it is very fully informed of the needs of the advertising universities. Many posts are filled by a local man although the formality of advertising may be maintained. It is obviously undesirable in these cases to put candidates to the expense and inconvenience of applying for a vacancy which is more nominal than actual. But if the Bureau receives the help it needs, it can be of immense use to any universities arranging exchanges.

The second resolution dealt with the question of superannuation benefits. Though the importance of ensuring that a man does not suffer financial loss if he goes temporarily to another university needs no stressing, the method of achieving this end is extremely complicated. A committee was set up to inquire into the possibilities.

The question of travelling expenses is closely related. The cost of moving from one part of the Commonwealth to another is in itself sufficient to make the idea impossible for most aspirants. It was agreed to approach bodies or foundations which may have resources available for this purpose; and the Congress was given to understand that proposals would be sympathetically received by some at least of these foundations. It is quite certain that no exchanges can be successfully arranged unless the finances are arranged in such a way as to make the project if not attractive at least reasonable, from the point of view of the scholar or student who is contemplating migration.

The Congress had before it a report written by Mr. Douglas Veale, registrar of the University of Oxford. Mr. Veale has recently been in Australia and wrote an account of his visit and put forward several recommendations as a result of what he had learned. As his memorandum took the form of a report to his own University, it was not discussed by the Congress; but it included the greater part of what the delegates to the Congress were seeking.

and, moreover, it put it in a form which implied that it would not be impossible to implement the proposals almost at once.

Mr. Veale's first recommendation was based on the fact that universities in Britain are overcrowded and under-staffed. A great part of the extra burden which is now being borne in British universities could be shared with young postgraduates from abroad—preferably young men immediately after their appointment to lectureships at their own universities. There would be no difficulty in asking them to take a few hours teaching, by which means they could supplement their incomes without making it impossible to do research work on their own. Mr. Veale found that the idea of combining teaching and research in this way would be welcomed by the Australian universities; and there is every reason to think that it would be to the advantage both of the teacher and of the taught.

Mr. Veale's other recommendations were closely in line with the resolutions which the Congress had passed. The discussion and the resolutions showed two things very clearly: first, a realization on the part of universities in all parts of the Commonwealth that it would be greatly to the advantage of all concerned if they could know each other better, and make more frequent exchanges of men and ideas; secondly, a determination to overcome the difficulties which are at present obstructing the way. A great deal depends on the reports which will be issued by the committees set up by the Congress at Oxford.

HEALTH OF THE PEOPLE OF BRITAIN

THE report of the Ministry of Health for the year ended March 31, 1947 (Cmd. 7441, pp. 1–204. London: H.M. Stationery Office, 1948. 3*s.* 6*d.* net), records, in general, another favourable bill of health. In spite of the continuance of rationing and other controls, and of the various additional ingredients of that too-familiar conception 'austerity', the vital statistics and other features of this report suggest that austerity is not really doing the population of Britain very much harm. In the period covered by the report the birth-rate rose to 19·1 per thousand of the population, a figure which is the highest recorded since 1923; and the infant mortality-rate fell to 43, which is a new low record. Maternal mortality also fell to a record low level of 1·43 per thousand total births, and death-rates at ages of less than fifteen years from measles, scarlet fever, rheumatic fever and heart disease were all the lowest ever reported. The death-rate was 12·0, which is the lowest since the previous best (11·6) in 1938.

One of the outstanding features of the year was the success of the diphtheria immunization policy. Deaths from this disease numbered 472, instead of the 2,361 reported in 1938, and there was a fall of 36 per cent in the notifications of diphtheria as compared with the year 1945. The greatest proportional decline was in the age-group 5–10 years (42 per cent), and the next greatest in the age-group 10–15 years (39 per cent). These figures speak for themselves; but the warning is issued by Sir Wilson Jameson that continual control of the antigens used for the immunization and maintenance of a high proportion of immune children are essential if this excellent result is to be maintained.

Encouraging also is the fact that in 1946 new low records were reported for deaths in Britain from respiratory and other forms of tuberculosis. In 1946 the number of deaths from this cause was 22,847, whereas ninety years ago it was 66,000 in England and Wales among a population half its present size. The report wisely avoids complacency about this advance in the control of a disease which still causes nearly one third of all deaths at ages between fifteen and thirty-nine. More beds for tuberculous cases are urgently required to accommodate the long waiting lists, and just as urgent is the need for more staff. If, says the report, the staff had been available, half the patients awaiting treatment could have been given beds during the last two years.

Notifications of whooping cough were higher than in 1945, a fact which will not surprise the parents of young children; but deaths from this distressing disease were lower. A reliable prophylactic vaccine has yet to be found, but experimental work on this problem is being energetically continued.

A serious feature of the report is the great increase of syphilis. New male cases at treatment centres rose to 10,705, a figure which is nearly double that of the previous year. Female cases, on the other hand, were 6,970 compared with 5,527 in 1945. An increase of 1,654 in the deaths from cancer is also recorded; but the report emphasizes that modern methods of treatment of this disease can do much to relieve the pain and suffering that it causes.

Among the many interesting facts recorded in the report is the slight decline since the middle of 1945 of about three-quarters of a pound in the average weights of adults aged twenty-five to fifty-four; but the improvements in the heights and weights of school children recorded during the later years of the War have been, on the whole, maintained. Nutritional surveys have shown that only 33 out of 7,216 persons in various parts of Britain could be classified as badly nourished.

During the first six months of 1946, smallpox was a continual menace because of the heavy return traffic from India by sea and air; but the energetic action of the health authorities confined the outbreaks that occurred within narrow limits. Readers of this part of the report will realize how much steady and unrecorded work is continually being done to safeguard the health of the people; and travellers by sea and air who read it in conjunction with the section dealing with the control of airborne and seaborne disease will understand that any regulations to which they have to submit when they enter Britain are not lightly imposed. In these days of rapid travel over great distances, it is clearly the duty of every traveller to see that he does not wittingly carry into the country which he visits diseases which may be deadly to the people living there.

It is not possible in a short review to record all the other interesting features of this comprehensive report. Apart from the facts it gives about the incidence of diseases other than those mentioned above, it includes discussions of the work of the emergency public health laboratory service, now a permanent feature of the medical organisation of the country, and of the excellent work being done on all aspects of maternal care, nutrition, the improvement of hospitals and their conflict with the building restrictions, water supplies, health publicity and other aspects of that proteus which we call public health. If there be anyone who doubts that the best effort and brains are being employed in this beneficent work, he should read this report and learn the truth. It will tell him, not about politics, but solely about the control and relief of suffering and the maintenance of the health of everybody. For that reason all those whose work is recorded or implied in its pages must feel gratified that their efforts have produced, in spite of the difficulties of these times, so much that is positive good and so much, also, that points to even greater achievements in the future. G. LAPAGE

BRITISH COUNCIL

ANNUAL REPORT

THE report of the British Council for the year ended March 31, 1948, refers to the withdrawal of its activities from Iceland, Switzerland, French North Africa, Bolivia, Ecuador and Paraguay and the closing of institutes and provincial offices in Belgium, the Netherlands, the Argentine, Colombia, Chile and Peru. To meet the reduction in funds for 1948–49 from £3,500,000 in 1947–48 to £3,150,000, further reductions in services such as books, drama and films are also being made. During the year, however, the educational work of the Council has steadily developed. It has continued to secure or to recommend British candidates for posts in foreign universities, and forty-two posts, mostly professorships and lectureships, are now subsidized and filled by the Council, and of these ten were filled in 1947–48. The Council has also assisted in the recruitment of suitably qualified staff from Britain for British and foreign schools in many countries overseas, and during the year launched a new scheme of bursary awards designed to bring to the United Kingdom persons who would not normally qualify to obtain scholarships but who, being actively engaged in industry or professional work, would benefit from a short stay in Great Britain and from mixing with those of like occupations.

The large volume of scientific bibliographical inquiries and requests for scientific information has made it necessary to amalgamate the science libraries and scientific information services. Assistance was given to the convening bodies of scientific conferences held in the United Kingdom, and a conspectus of current scientific research in Britain has been compiled and is maintained with the co-operation of numerous bodies and by visits of Council staff to university research departments. The publication *Monthly Science News* has been replaced by the larger journal *British Science News*, and assistance has been given in placing agricultural scholars of the Council and in arranging tours for some fifty agricultural visitors. The collection of seed samples from a large number of countries was organised at the request of various research stations, and advice and assistance given to 103 private students from ten countries and to 32 engineers and technicians from thirteen countries on visits to Great Britain. The medical library and information service has expanded considerably, most of the 284 books added being received for review in the *British Medical Bulletin*, while 310 copies of the monthly list of new British medical publications are circulated to libraries and institutions abroad.

Programmes of work were arranged for more than forty overseas medical graduates holding British Council scholarships, and the Council is also arranging programmes or accommodation for most of the 'fellows' appointed by the World Health Organisation who elected or were advised to study in Britain. The Council's organisation for receiving visitors was increasingly used by Government departments, overseas Governments, universities and professional societies. Besides the 599 who came as the Council's guests, forty per cent of whom were concerned with science, medicine, agriculture and engineering, 306 who came without financial assistance from the Council had programmes arranged for them. The Council also financed a limited number of delegates to scientific conferences and cultural events, and was also invited by several universities to assist recruitment for their summer schools. The Council took the initiative in convening a committee representing British universities to discuss the possibility of organising a series of summer schools in 1948, designed particularly for American students. The scheme involves a total of 700 students, for nearly 200 of whom from overseas the Council has accepted responsibility.

Reports on activities overseas are considerably curtailed in comparison with previous reports and contain little reference to scientific activities except in Finland, Italy, Poland and Brazil. The slightness of the accounts of the scientific activities of the Council constitutes one of the chief criticisms of the report, although the figures quoted for exchange of students and the like do not suggest that science is not well represented in the Council's activities, or support the impression that might be derived from other passages of the report that the Council is becoming increasingly an instrument of political warfare.

It is perhaps natural that, in view of the searching examination to which the activities of the Council were subjected by the Select Committee on Estimates in a report published last April, some space should be given to comment on the Select Committee's report. While satisfied that the evidence indicated that the Council is regarded as outside politics and that its work is not associated with propaganda or the political feeling of the day, the Select Committee directed attention to the need for introducing an improved permanent service, and questioned the necessity for so heavy a staff at headquarters. Without going closely into the important question of recruitment, the report indicates that the British Council itself leans towards the view of the Select Committee that Civil Service standards should be applicable in recruiting the bulk of its staff. No agreement has yet been reached, however, on the question of the grades and conditions of service which will ensure the maintenance of efficiency everywhere and adequate representation overseas, nor does the fundamental question appear to have been considered whether the service of the Council should constitute a closed service or whether its staff should comprise mainly those seconded for fairly short periods and then returning to academic life or their normal occupation. The Council hopes for some reduction in staff as a result of careful overhaul of establishments at headquarters, but fears that the financial savings will be absorbed by overdue improvements in staff conditions. Staff questions may not figure so prominently in future reports, but whether they do or not, the report might reasonably be expected to provide fuller public explanation as to how and by whom the plans for our cultural strategy are prepared.

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Saturday, October 9

North of England Institute of Mining and Mechanical Engineers (at Neville Hall, Newcastle-upon-Tyne), at 2.30 p.m.—Mr. Haswell Alder: Inaugural Address as President.

Tuesday, October 12

Scientific Film Association (at the Royal Institution, Albemarle Street, London, W.1), at 10 a.m.—Conference on "The Film in Scientific Research" (to be opened by Sir Robert Watson-Watt, F.R.S.).

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Mr. Bernard Fagg: "The Beginnings of Art in Northern Nigeria".

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.8), at 5 p.m.—Scientific Papers.

Institution of Electrical Engineers, Measurements Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Dr. S. Whitehead: Inaugural Address as Chairman.

Illuminating Engineering Society (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. J. M. Waldram: Presidential Address.

Manchester Geographical Society (in the Geographical Hall, St. Mary's Parsonage. Manchester), at 6.30 p.m.—Mr. J. M. Wordie: "Explorations in Graham Land and in the South Shetlands".

Textile Institute, Yorkshire Section (at the Midland Hotel, Bradford), at 7 p.m.—Mr. J. Foster Beaver: "The Romance of Wool".

Society of Instrument Technology, North-West Section (joint meeting with the North-Western Branch of the Institution of Electronics, in the College of Technology, Manchester), at 7.30 p.m.—Mr. D. Edmundsen: "Electronic Development in Instrumentation".

British Psychological Society, Social Psychology Section (in the Physiology Theatre, University College, Gower Street, London. W.C.1), at 8 p.m.—Dr. Ruth Griffiths: "Measuring the Abilities of Children in the First Two Years of Life".

Wednesday, October 13

Royal Sanitary Institute (at 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Discussion on "The Control of Milk Quality" (to be opened by Mr. E. B. Anderson and Mr. L. J. Meanwell). (Members of the Food Group of the Society of Chemical Industry are invited.)

Physical Society (joint meeting of the Colour and Optical Groups, at Northampton Polytechnic, St. John Street, London, E.C.1), at 3 p.m.—Scientific Papers.

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. Pentti Eskola: "The Problem of Mantled Gneiss Domes" (Fourth William Smith Lecture).

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. F. Smith: Inaugural Address as Chairman.

Society of Chemical Industry, Food Group (joint meeting of the Microbiological and Nutrition Panels, at Gas Industry House, 1 Grosvenor Place, London, S.W.1), at 6.15 p.m.—Dr. E. F. Gale: "The Role of Vitamins (and Metals) as Co-enzymes in Bacterial Metabolism".

Royal Institute of Chemistry (at I.C.I. (Paints), Ltd., Wexham Road, Slough), at 6.30 p.m.—Mr. G. R. Cornish: "Methods of Determining Molecular-Weights of Polymers"; Mr. C. H. Young: "The Performance of Paint Films".

Tuesday, October 12—Wednesday, October 13

Society of Chemical Industry (at Geneagles Hotel, Gleneagles).—Convention on "High Vacua".

Thursday, October 14

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. Joseph Pearson: "The Marsupial Placenta".

Physical Society, Acoustics Group (in the Small Physics Theatre, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 5 p.m.—Mr. W. West: "The Accuracy of Measurements by Rayleigh Disc".

Illuminating Engineering Society, Manchester Centre (joint meeting with the Northern Local Committee of the British Optical Association, in the Reynolds Hall, College of Technology, Manchester), at 5.30 p.m.—Mr. W. J. Wellwood Ferguson: "Colour".

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. K. B. Ross and Mr. D. N. McKinlay: "Integration of Operations in a Large Refinery".

Institution of Electrical Engineers, Utilization Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. R. O. Ackerley: Inaugural Address as Chairman.

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7 p.m.—Scientific Papers.

Friday, October 15

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Mr. W. A. W. Fox: "Transverse Navigation, an Alternative to the Grid System".

Royal Institute of Chemistry (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Prof. H. B. Nisbet: "Anæsthetics".

North-East Coast Institution of Engineers and Shipbuilders (at the Literary and Philosophical Society, Newcastle-upon-Tyne), at 6.15 p.m.—Mr. Mungo Campbell: Presidential Address.

Society of Dyers and Colourists, Manchester Section (at the Gas Department Showrooms, Manchester), at 6.30 p.m.—Prof. W. T. Astbury, F.R.S.: "Adventures with the Electron Microscope".

Plastics Institute (at the Engineers' Club, Albert Square, Manchester), at 6.45 p.m.—"A Review of Thermoplastic Materials" (Chairman's Address).

Society of Glass Technology, North-West Section (at the Gas Showrooms, Radiant House, St. Helens), at 7.15 p.m.—Dr. B. P. Dudding: "Statistical Methods and Industrial Efficiency".

Saturday, October 16

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 2.30 p.m.—Mrs. Bertild Bekker: "Peoples in the Mountains of Central Celebes".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lectureship in Mechanical Engineering—The Registrar, King's College, Newcastle-upon-Tyne (October 16).

Senior Assistant in Structural Engineering, a Responsible Lecturer in Organic Chemistry, Lecturers (2) in Chemistry, and a Lecturer in Mechanical Engineering, in the Constantine Technical College—The Director of Education, Education Offices, Middlesbrough (October 16).

Lecturer in Biological Subjects (Botany and Zoology)—The Principal, Central Technical College, Suffolk Street, Birmingham 1 (October 16).

Research Assistant for experimental work in collaboration with clinical research teams, in particular in the Department of Otology—The Secretary, Middlesex Hospital Medical School, London, W.1 (October 16).

Lecturer in Mechanical Engineering Drawing to H. N. C. standard—The Chief Superintendent, Telecommunications Research Establishment, Great Malvern, Worcs. (October 16).

Lecturer in the Department of Physics and Mathematics of the City Technical College—The Director of Education, 14 Sir Thomas Street, Liverpool 1 (October 18).

Senior Assistant in Organic Chemistry—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (October 20).

Plant Pathologist to undertake research on virus diseases of fruit plants, a Physical Chemist in the Plant Protective Chemistry Section to work on problems involved in the control of pests and diseases of fruit, a Research Entomologist to be attached to the Plant Protective Chemistry Section for laboratory and field studies of insecticides and their mode of action, a Junior Organic Chemist in the Biochemistry Section for work on the organic constituents of fruit-bearing plants, an Honours Graduate in natural science with special interests in plant physiology and botany for work on frost damage to fruit plants, and an Assistant for maintenance and construction of experimental apparatus, including thermo-electric instruments, for work on frost damage to fruit plants—The Secretary, East Malling Research Station, Maidstone, Kent (October 23).

Lecturer in Philosophy—The Very Reverend the Dean, Christ Church, Oxford (October 25).

Smithson Research Fellowship—The Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W.1 (October 30).

Lecturer in Physical Chemistry in University College, Ibadan Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (October 31).

Assistantship in the Department of Zoology—The Secretary The University, Old College, Edinburgh 8 (November 1).

Chief Mechanical Engineer (under the Chief Mechanical and Electrical Engineer) in the Production Department at Headquarters in London—The National Coal Board, Establishments (General Branch, Hobart House, Grosvenor Place, London, S.W.1, endorsed TT/90 (November 15).

Professor of Botany at the Imperial College of Tropical Agriculture, Trinidad—The Secretary, Imperial College of Tropical Agriculture, Grand Buildings, Trafalgar Square, London, W.C.2 (December 15).

Reader or Senior Lecturer in Biochemistry in the Department of Physiology, University College of the West Indies—The Secretary Special Committee of the Senate on Higher Education in the Colonies University of London, Senate House, London, W.C.1 (January 15)

Tucker-Price Scientific Research Fellowship for research in Mathematics, Science, or an allied subject—The Secretary, Girton College, Cambridge (January 15).

Lecturer with special qualifications in Analytical Chemistry and some inorganic interests, and a Lecturer with special qualifications in Organic Chemistry—The Secretary, The University, Aberdeen.

Laboratory Technician in the Department of Pathology—The Pathologist, Royal Devon and Exeter Hospital, Exeter.

Laboratory Technicians in the Biochemical Research Department—The Secretary, Institute of Psychiatry, Maudsley Hospital Denmark Hill, London, S.E.5.

Graduate (or equivalent) for Analytical Laboratory—The Assistant Secretary, British Coal Utilization Research Association, Randall Road, Leatherhead.

Senior Assistant in Civil Engineering, and a Lecturer in Mechanical Engineering—The Clerk to the Governing Body Battersea Polytechnic, Battersea, London, S.W.11.

Economic Statistician or Economist for investigations in economic and social relations between agriculture and industry, and a Research Assistant in Rural Social Organisation—The Secretary, University of Oxford Agricultural Economics Research Institute, Parks Road Oxford.

CULTURAL AND SPIRITUAL PROGRESS OF MANKIND

MUCH of the Lambeth Conference report* deals with matters which are not the immediate concern of men of science as such; but two of the committee reports and certain passages in the Encyclical Letter are of interest in view of the increasing concern of the scientific world with the ethical aspects of atomic warfare, and of the attempts being made to formulate a professional code on the lines of the Hippocratic Oath. Moreover, a number of men of science have taken a prominent part in the movement to formulate a declaration of human rights, and on this also the report has something of interest to say. Thus even if their interest is indirect and by virtue of their citizenship rather than their professional activities, scientific workers cannot be altogether indifferent to any document that in any degree helps to clarify thought on the moral and spiritual values that form the real foundation for any attempt at union of the Western democracies. The frankness, clarity and logic of the whole report will indeed commend it to many outside the Anglican Communion, even if they do not always accept its premises or draw the same conclusions, at least without some reservations. The final invitation to all men and women to join in the war against the evils which wreck man's life and against the false creeds which debase it will be welcomed by many men of science.

The Encyclical Letter is noteworthy for a lucid restatement of the Christian doctrine of man as opposed both to Communism and nation worship. The claim for freedom is put in terms which many men of science will support, as they will welcome the insistence that rights imply duties which must be faithfully discharged. The Letter welcomes the great expansion of man's understanding of himself and of the world; but points out that knowledge may be used by man for self-destruction, and his greatest inventions turned to his ruin unless he learns to discipline his own nature and his powers. In forthright terms the claim that man should give himself entirely in obedience and service to the nation or group of which he is a member is rejected. Society exists to serve the needs of its members, not to enslave and possess them wholly, and the Letter maintains uncompromisingly that Christians must reject the Marxian Communism which exalts atheism and puts supreme confidence in material progress, and must condemn the cruelties, injustice and false propaganda inherent in it.

Neither the Letter nor the report as a whole fails to recognize that Communism to many people appears as a protest against social injustice, and it is urged in the report that it is the special duty of the Christian Church to oppose the Marxian challenge by sound teaching and the example of a better way. Firm support is also given to the work of the Commission of the United Nations on Human Rights. The Letter also calls on all nations collectively to control the manufacture and use of atomic power, and to pledge themselves never to use it for the purposes of war; and it calls upon the nations even at the price of limiting their own sovereignty to work together to remove the causes of war and to promote human culture and welfare.

---

* Lambeth Conference, 1948: The Encyclical Letter from the Bishops, together with Resolutions and Reports. Pp. v+53+iv+120. (London: Society for the Propagation of Christian Knowledge, 1948.) 5s.

In one of its resolutions on the Church and war, the Lambeth Conference affirms that it is the duty of governments to work for the general reduction and control of armaments of every kind and for their final elimination, except those which may be necessary for international police protection. Nevertheless, it recognizes that in the meantime there are occasions when both nations and individuals may be obliged to resort to war as the lesser of two evils, though the present report adds little to what was said on this subject earlier this year in "The Church and the Atom", which was prepared by a commission appointed by the Archbishops of Canterbury and York. The report of the Committee on the Church and the Modern World shows that the thought of the Conference ran on similar lines to that of the Commission; although the report presents not so much a challenge to thought, as did that of the Commission, as a call to action to combat the present disastrous trend towards another world war. It rightly points to the danger in the growing fatalism on this subject, and reminds us we can have either war or civilization—not both.

The value of the United Nations Organisation is recognized; but it is pointed out that any such organisation must be permeated with moral and spiritual power. Again the report calls for endeavour to remove the causes of war by striving for greater economic well-being throughout the world, greater emphasis on social welfare, better observance of human rights in every sphere, and more constant use of international negotiation and conversation. Equally, the inherent danger of unbridled arrogant nationalism is faced. In the sections on the Church and the modern State, the challenge of dictatorship is repudiated as inconsistent with the Christian way of life and as offering an absolute conflict of values whether the basis of the dictatorship is a secular or a religious view of life; but it is not claimed that a parliamentary democracy is the only alternative to dictatorship in the modern world. On the contrary, a contribution is offered towards thinking out afresh the terms of co-operation, and towards a fresh experiment in co-operation, which merits the attention of all concerned with the problem of active democracy and the preservation of individuality and initiative under the present conditions of industry, commerce and society.

In a further section, there is a dignified and searching analysis of Communism which recognizes that Communism cannot be overcome by argument alone. It has to be outlived, not merely outfought. The positive suggestions made here should command approval and support far outside the Anglican Communion. To proclaim human rights without equivocation and respect them in practice; to do full justice to the truth in Communism; to recognize that the acceptance of an economic theory of Communism as distinct from Marxian atheism does not involve exclusion from the fellowship of the Christian Church; and to appreciate fully the immense contribution which science and technology have made to human welfare, and the dedicated lives of countless men of science and technicians—these are means which commend themselves to men and women of goodwill, and are already the basis of constructive contributions to human welfare and new experiments in communal living.

In the sphere of education, although there is little in the report that is new, there is much that will be welcomed. The most pressing need here, it is urged, is a *rapprochement* between religion and science, and the harnessing of scientific means to Christian ends. The Conference affirmed its belief that a fresh understanding of the nature and function of universities is greatly needed, and in that reassessment the place of theology in its full meaning must be duly considered.

Clearly it lay outside the scope of the Lambeth Conference to offer suggestions for dealing with such dangers as excessive specialization and the consequent lack of integration; but the report offers a real contribution towards supplying that clear sense of purpose the absence of which it regrets. The central problem of the relation of knowledge and power is fairly and squarely faced.

Through the new discoveries and inventions of our own time, man has gained power for the better ordering of the world. Those possessions now necessitate new forms of social organisation and the transcendence of outworn experiments in our ways of living and social institutions as the very condition of our survival. The over-riding task when all human values are threatened and man is being reduced to insignificance by forces beyond the individual's control is the vindication of man against all that cheapens or degrades him, and the rebuilding of a culture in which personal life holds the acknowledged primacy.

Whether or not they follow the argument of the report in its further searching and often stimulating analysis of man and his nature, scientific workers could scarcely wish for a fairer statement of the main issue. The Conference welcomed the great advance in scientific discovery characteristic of our age and repudiated the suggestion that any check should be placed upon it. Men of science, on their part, have also recognized that the consequent growth of man's knowledge increases his moral responsibility for the use and misuse of it. They will note with appreciation, also, the welcoming without reserve of the findings of scientific investigation into man's psycho-physical constitution, and the respect for the vocation of the man of science as a service to the God of truth. They, too, admit the desperate need for bringing technical discovery into true line with ethical direction, and that political freedom is everywhere in imminent danger because men shirk the price that must be paid for it and are prone to evade that responsibility, whether intellectual, civic or moral, by which alone it can be main tained. They, too, recognize that the hope that free institutions can be safeguarded on a secular basis must prove self-defeating, and some at least repudiate a determinist theory of history. If some cannot accept in their entirety the premises and conclusions of Christian thought even as displayed in the Lambeth Report, they may, none the less, be grateful for the evidence it affords of powerful support for many of the policies which they would wish to see pursued. The resolutions of the Conference may well lead to action and to the mobilization of moral and spiritual power behind the measures necessary no less for the furtherance of science than for the preservation of society and its highest cultural and spiritual values.

THE EINSTEIN ENIGMA

Einstein

His Life and Times. By Philipp Frank. Pp. 367. (London: Jonathan Cape, Ltd., 1948.) 16*s*. net.

THOSE who, like the present reviewer, are personally unacquainted with Einstein, will read this book with a shock of surprise. While Dr. Frank's sympathies are all with Einstein, the portrait presented to us is not altogether a pleasant one. We see a man developing early into the traditional type of nineteenth-century 'professor'. He regards himself as free to develop any eccentricity of behaviour, whether those about him like it or not, and to talk shop in season or out of season, a characteristic illustrated (p. 144) by the description of a courtesy visit to a non-mathematical colleague in Berlin, in which, after subjecting his hosts to a forty-minutes discourse on relativity, Einstein left abruptly. This lack of appreciation of the fact that ideas and interests which did not happen to interest him might still be as valuable as those that did may well explain Einstein's difficulties in the Berlin Academy, or his failings as a teacher. Always, apparently, ready to lecture on his researches of the moment or to deliver popular discourses, Einstein was not prepared to teach his students systematically what they had need to learn. An attitude of this kind is not incompatible with a deep concern for abstract causes such as pacificism or Zionism, and his lack of human contacts had one good result: it turned Einstein in the early 1920's from becoming a political leader of the Zionist movement. But there is another side to the picture: an impulsive kindliness made him only too ready to help refugee scholars after 1933, or to aid by correspondence a student in Prague (p. 331), or to instruct in arithmetic, at her own suggestion, a little girl of ten who lived near him in Princeton (p. 356).

Dr. Frank does not, of course, aim at an exposition of relativity theory; but he does describe Einstein's philosophical views in some detail (pp. 259 and 336). Einstein adopts a logical positivist view on the basic theoretical laws of Nature, which are for him free creations of the imagination confirmed by observation. Logically, this should lead to the acceptance of Newtonian mechanics as an equally good alternative to relativistic mechanics when we reflect on the enormous body of observational confirmation the [illegible] receive in engineering and astronomy, for example. At the same time, Einstein holds a realist view on electromagnetic and gravitational fields, light, atoms, electrons, etc. They are 'physical realities' and not concepts freely created for the purpose of interpreting observations. Nor is it easy to see how a belief in the rationality—almost the mathematical character—of Nature (p. 340) can be reconciled with his view of the character of scientific law. If Nature is rational, surely its laws are there to be discovered, and not created, by the man of science?

Dr. Frank's account of the times in which Einstein lived is written from the point of view of a Central European who sees Germany and her immediate geographical neighbours as the world-focus of scientific activities. Many quotations illustrate the strange vagaries of the totalitarian mind: in Nazi Germany relativity theory is the expression of Jewish physics, in Russia the theory is at first contrary to and later in accordance with dialectical materialism. Dr. Frank's selection among Einstein's contemporaries of those worthy of mention is very odd indeed. The venomous ideological crank, Philipp Lenard, is often referred to and freely quoted; but men who most nearly reached Einstein's intellectual stature and who developed and made known the theory of relativity receive scant attention. Hermann Weyl and de Sitter are not mentioned at all, and the three references to Eddington scarcely do justice to his contributions to the theory. Indeed, Einstein is credited (p. 326) with proving after 1933 that the geodesic principle is deducible from the field equations, though a proof of this theorem is to be found in the "Mathematical Theory of Relativity" written in 1923. Again, from pp. 346–351, we obtain the impression that the atom bomb was due to the scientific and political efforts of Einstein, O. Hahn, L. Meitner, E. Wigner, E. Fermi and L. Szilard. Even if Chadwick and Cockcroft are not worthy of mention, surely some native-born American physicists had a hand in the matter!

THE CAVITY MAGNETRON

Microwave Magnetrons

Edited by George B. Collins. (Massachusetts Institute of Technology; Radiation Laboratory Series, Vol. 6.) Pp. xviii + 806. (New York and London: McGraw-Hill Book Co., Inc., 1948.) 54*s*.

THE origin and excellence of the Radiation Laboratory Series of monographs is now well known, and can need little in the way of introduction to the physicists and engineers on both sides of the Atlantic who took part in the great war-time venture of radar. Without the cavity magnetron it is more than doubtful whether micro-wave radar could have become the decisive weapon it turned out to be. In this sense, therefore, the volume under review is perhaps the most important of the series, providing the central theme without which many of the other volumes could not have been written.

The cavity magnetron as a micro-wave generator of pulsed power of the order of a few kilowatts was taken to the United States by Sir Henry Tizard and Prof. J. D. Cockcroft in May, 1940, in a form entirely suited to manufacture; and this after only a few short months of work by those concerned. This early work, the later use of higher peak voltages and magnetic fields, the introduction of strapping in 1941, and the later achievements of peak powers of 2 or 3 × 10^6 watts at a frequency of 3 × 10^9 mc./sec., are efforts of which British physicists and engineers in universities and in industry may be justly proud. Much also of the development of an adequate theory of the magnetron was carried out in Britain by Hartree and Stoner and their collaborators. The method of the self-consistent field so strikingly successful in atomic physics proved equally valuable in the theoretical study of the magnetron. The Physics Department of the University of Birmingham, under the direction of Prof. M. L. Oliphant, was the centre from which sprang much of the experimental scientific effort on magnetrons in Britain or any other country. Oliphant, and no doubt others, recognized at an early stage the significance of obtaining high powers at centimetre wave-lengths. The klystron at that time was limited by a comparatively low beam current, but had the advantage of cavity resonators. The basic problem at the end of 1939 was to decide on a device which would take advantage of an enclosed resonator system and be much less limited in current. The cavity magnetron was the answer. In looking back on this venture, I think it is fair to comment that no other war-time effort has shown so well the original approach of British men of science to new problems; for not one of the team there collected could claim to have any prior experience in the field of microwave generators.

The approach of the Radiation Laboratory to the problems of the magnetron, as to other aspects of radar, was, as a result of the pioneer work carried out in Britain, bound to be rather different. The great American effort on the magnetron was one largely, perhaps, directed to understanding, consolidation, and manufacture rather than new discovery; at least that is the way things turned out. There are, of course, exceptions to this, such as the 'rising-sun' magnetron, a development arising entirely from the Columbia Laboratories. The volume under review pays only a brief tribute in its early pages to the British effort on the magnetron, and gives little idea of how the work developed. The book is a detailed analysis of the properties and behaviour of the cavity magnetron; it is not the story of the magnetron, nor is it intended to be. But it is a pity that time could not have been found for a more adequate survey of the development of ideas, experimental results, and theories from the numerous N.D.R.C. and C.V.D. Reports available to the authors. "Microwave Magnetrons", in short, gives a tremendous impression of knowledge of the subject, but gives little idea of how that knowledge grew from stage to stage.

Like other volumes of the series, "Microwave Magnetrons" is not easy meat for the uninitiated. The book contains a good introduction by its editor G. B. Collins, and is thereafter divided into five parts: resonant systems; analysis of operation; design; tuning and stabilization; practice. Parts I, II, III each contain four chapters and Parts IV and V three chapters each. The purpose of Part I is a discussion of the fundamental electromagnetic properties of the resonant system and the output circuit. Three types of resonant circuit are dealt with: the unstrapped system, the rising-sun system, and the strapped system. In Part II the operation of the magnetron is analysed first by a study of the interaction of the electrons and the electromagnetic field; this is followed by chapters on the space charge as a circuit element, transient behaviour involving a discussion of the starting of oscillation; and a discussion of noise.

Part III opens with a valuable discussion of the principles of design, and lays emphasis not only on the fundamental parameters but also on those of importance to the user. A discussion on resonant systems, cathodes, and a short chapter on permanent magnets make up the remainder of Part III. Part IV is concerned with tuning and stabilization. Part V is devoted to American manufacturing methods, and as such is admirable. Chapter 19 describes typical magnetrons, all American. Those interested in the contributions of British science and engineering to the study and manufacture of the cavity magnetron will regret that more space could not have been found for a discussion of their efforts in this key volume, which remains, nevertheless, a most imposing monograph on 'the heart of radar'.

J. T. RANDALL

PSYCHOLOGY AND MYSTICISM

Hindu Psychology

Its Meaning for the West. By Swami Akhilananda. Pp. xviii + 241. (London: George Routledge and Sons, Ltd., 1947.) 12*s*. 6*d*. net.

THE title of Swami Akhilananda's book is misleading to the Western reader. It is not quite clear what he means by Hindu psychology. A clue is given in Prof. Brightman's introduction in which he says "The purpose of this book is not to lead him *to substitute Indian Psychology for Christianity or Judaism*". Hindu psychology is, then, something which could take the place of a religion.

Although the Swami does not define Hindu psychology, he states that its method is "training the total mind of the individual, including thought, emotion and will". This is an entirely different conception of method from that of the European and American schools of psychology. It is well to bear in mind when reading this book the enormous chasm separating the Hinduism of the cultured classes from that of the masses in India; and it must also be realized that Hinduism is not only a religion but also a social system, the basis of which is caste.

The essence of higher Hinduism is a belief in the unity of being. "Knowledge of eternal truth belongs to those and only those who see but One in the manifold changes of the Universe". This religious philosophy is evident in Swami Akhilananda's work.

The book begins with a very brief outline of Western schools of psychology which are not, in the author's opinion, concerned with the "total mind", an abstraction not defined. The psycho-analytic concept of two layers of mind is also considered inadequate. The Hindu psychologists recognize four states of consciousness: the sleeping and dreaming states, which are included in the subconscious of Western terminology, the conscious, and the superconscious. It is in its concern with the superconscious states (not to be confused with telepathy and clairvoyance) that Hindu psychology is unique.

The chapters dealing with meditation and its effects, insight, extra-sensory experiences, and the superconscious state, are the most interesting, but bewildering to the reader unaccustomed to Eastern mysticism.

The sincerity of Swami Akhilananda is obvious and Western pride in its scientific attitude is shaken by this statement: "It is true that the Occidenta countries, with the help of scientific achievements, have done a great deal for the betterment of the everyday life of man. Yet in the West, because of the restlessness, unhappiness, and dissatisfaction of the mind, there are constant conflicts and frustrations resulting in extreme forms of mental disorders, nerve troubles, and functional ailments. This shows that the modern ways of life, based on scientific discoveries and their uses, have not solved the psychological problems of the West. On the other hand, the problems are becoming more and more frightening. So the West must find a way out of this dangerous situation". D. M. WHEATLEY

QUASI-ABELIAN FUNCTIONS

Funzioni quasi-abeliane

By Prof. Francesco Severi. (Pontificiæ Academiæ Scientiarum Scripta Varia 4.) Pp. 327. (Rome: Pontifical Academy of Sciences, 1947.) n.p.

THE present treatise, constituting almost entirely an original work, was written during 1944–45 and communicated as a memoir to the Pontifical Academy of Sciences, by which it has been published as one of a series of monographs. Its purpose is to fill an obvious gap both in the theory of algebraic functions and their integrals and in the relevant geometrical literature, subjects to which Prof. Severi has made masterly contributions during the last forty-five years. The concept of quasi-Abelian function, in its simplest form, has its origin in a theorem of Weierstrass, which asserts that the only uniform functions of a complex variable possessing an algebraic addition theorem are the elliptic functions and their degenerate forms, namely, the exponential and rational functions. The functions of the last two types are the quasi-Abelian functions relative to the elliptic function.

In his treatise Severi is primarily concerned with the solutions of the generalized problem, that is, the uniform functions of any number of complex variables which possess an algebraic addition theorem; for solutions of the most general kind—the so-called Abelian functions—there already exists a very great literature extending over more than a century, but hitherto there has been no systematic treatment of the degenerate forms. As Severi shows, these are likewise periodic functions in general, though with fewer periods than the associated Abelian functions, and in many respects are strictly analogous to the Abelian functions themselves.

Severi's investigation is, naturally enough, in the tradition of the Italian school of algebraic geometry, which, taking its cue from the Germans Brill and Noether, has translated the discoveries of Abel, Jacobi and Riemann concerning multiply-periodic functions into the language of the geometry of curves. For this purpose it employs a strikingly simple technique, depending on the consideration of sets of points on an algebraic curve, from which results not only a remarkable gain in elegance and power, but also a method capable of extension to similar problems of a more complex nature. To this method Severi has now added a concept which has already played an essential part in other researches of his: thus while, according to the classical theory, an algebraic plane curve of degree n, possessing d double points, has a genus p given by the formula $p = \frac{1}{2}(n-1)(n-2) - d$, Severi's innovation consists in regarding a certain number of these nodes as virtually non-existent, so that the curve has a *virtual genus* greater than p.

The first section of the treatise—about one-third of the whole—is in the nature of a prelude, devoted to the theory of series of points on a curve. The next two sections deal with the quasi-Abelian functions in all their generality, their periods, the associated integrals and allied geometrical results concerning the so-called Picard variety attached to a curve of genus p. Severi begins by posing three alternative definitions of the functions, and eventually shows that all three are equivalent to the one already stated above; here, it must be noted, certain parts of the theory hinge on a hypothesis of a geometrical character which has so far not been established. The last section, which is comparatively brief, completes an interesting chapter in the theory of surfaces. It is just forty years since Enriques and Severi wrote their prize memoir (*Acta Mathematica*, 1909–10) on hyperelliptic surfaces, that is, surfaces the coordinates of the points of which are expressible as uniform quadruply-periodic functions of two independent variables; an example is Kummer's quartic surface, which itself includes Fresnel's wave surface as a special case. The memoir has now been supplemented by a study of the quasi-hyperelliptic surfaces, which comprise Plücker's quartic surface, a familiar locus in line geometry; Severi shows how this is obtainable as a limiting form of Kummer's surface.

The book, which concludes with a detailed bibliography, is a notable addition to the distinguished author's publications, and will doubtless occupy a permanent place in the literature. L. ROTH

BLOOD PRESSURE

Blood Pressure and its Disorders, including Angina Pectoris

By Dr. John Plesch. Second edition, revised and enlarged. Pp. xiv + 307 + 15 plates. (London: Baillière, Tindall and Cox, 1947.) 21s. net.

THE first edition of this book by Prof. Plesch will be well known to most workers interested in this subject, and a second edition of it will be welcomed. Most of the chapters have been enlarged and some new ones have been added; references to the literature and case-histories increase the value of the book, and suggestions made by readers of the first edition have been incorporated. The author says that he has dealt only with aspects of the subject of which he has had practical experience through research and observation, and that he does not intend to present the reader with a text-book. This note of personal experience is evident on every page. It is a book for the progressive and open-minded worker who shares its author's evident desire to understand thoroughly the origins of the diseases discussed and to relieve the suffering that they cause by treatment based upon this understanding.

A short review cannot give an idea of the wide field covered by the text. Planned in three main sections, one on arterial blood pressure, one on venous pressure and one on the much-discussed conception of angina pectoris, the book deals with the physiological basis of disorders of the blood-pressure, their diagnosis and the clinical application of the facts discussed. No doubt many readers will be especially interested in the section entitled "Angina Pectoris", partly because the author does not restrict the conception of angina to spasms of the coronary arteries of the heart, but discusses it as "generally applicable to spontaneous cramps of any artery of the body".

We hear much nowadays about arteriosclerosis and high and low blood-pressures; but Prof. Plesch thinks that the danger of arteriosclerosis, at any rate, is over-estimated. Post-mortem examinations, made in different countries, of healthy young soldiers who fell in the First World War, show that 44·5 per cent of soldiers between the ages of twenty-one and thirty years of age and 62 per cent of those between thirty-one and forty years bore evidence of arteriosclerosis. These figures are surprising; but the mortality from this disease is only 6 per cent of the total mortality, and Prof. Plesch concludes that arteriosclerosis is not necessarily progressive and that it can be cured. During his valuable discussion of the general and symptomatic treatment of angina pectoris, he makes interesting observations on diet, the consumption of alcohol and smoking. Smokers will be especially interested in his analysis of various tobaccos and their effects.

An appendix discusses the use of the tonoscillograph and the interpretation of tonoscillograms, the author's techniques of auscultation and borderline percussion, the use of the blood-gas analyser with an absorption cell, and his experimental work on the immunization and sensitization of patients by injections of their own urine.

The book is well produced, and the photographic and other illustrations add much to its value.

THE BEHAVIOUR OF SEEDS

Twenty Years of Seed Research at Boyce Thompson Institute for Plant Research

By Lela V. Barton and William Crocker. Pp. 148 + 22 plates. (London: Faber and Faber, Ltd., 1948.) 21*s.* net.

FOR more than twenty years workers at the Boyce Thompson Institute at Yonkers, New York, have been publishing papers on the factors influencing the germination and continued viability of seeds. Their investigations have been not only of academic interest, but also of practical significance to people who produce, market, and sow seeds; and presumably it has been with this in mind that two of the senior workers concerned have now written a very brief summary of the Institute's work in this field. Farmers, gardeners and seedsmen will find this book giving, with a minimum of scientific terminology, confirmation, explanation and extension of much that they have discovered and guessed, and also some suggestive new facts.

Part 1 of the book reviews various types of delayed germination, due to the need for after-ripening, by drying, or by 'stratification' at low temperatures while moist, or to resistant seed coats, or to internal 'physiological' dormancy of root or shoot rudiments. The examples given underline the survival value of many of these peculiarities, and emphasize that sufficient knowledge of a plant's life-history and wild environment will provide a good basis upon which to forecast the conditions required for the most speedy and complete germination of its seeds. Apart from this, general principles are not easy to formulate. Although the seeds of related plants naturally tend to show similar behaviour, considerable variation can be found within the genus or even between varieties of the same species. In this wet harvest season of 1948 the British farmer is, once again, having thrust upon his notice the unfortunate readiness to 'sprout out' of the otherwise admirable wheat Holdfast, and the more stubborn initial dormancy of, for example, some varieties of Scandinavian origin. The same phenomenon is seen from another angle in the seed-testing laboratory, where freshly harvested wheats of the latter type are artificially dried at 40° C. as a matter of routine, or they tend to grow slowly and erratically in the test dishes.

A chapter, with the only plate in colour, is devoted to ways in which the capacity of seeds to germinate can be ascertained quickly without waiting for normal growth. The summary dismissal of chemical tests in favour of an excised embryo technique is unjustified. Unless the seed is large, the latter method requires a considerable amount of time and manipulative skill, and only yields results after some days; whereas sectioning of the soaked seed followed by treatment with a dilute aqueous solution of triphenyl tetrazolium chloride or bromide, a technique developed in Germany during the recent War, can give information in less than two hours, and has proved so practicable and reliable, at any rate with seed grain, that it is now regularly utilized by at least one commercial house.

Part 2 is concerned with the life-span of seeds and the effect on it of storage conditions, and here the authors are able to make the general recommendation that "rather low moisture content and/or low temperatures are effective for successful storage of vegetable seeds" and, in fact, of the majority of seeds. Here, again, generalization is unsafe. Barton and Crocker, for example, confirm the familiar observation that *Delphinium* seeds are short-lived unless specially stored. But 1938 seeds of *Delphinium denudatum* stored without special precautions and sown by the writer in 1939 and every year since, have shown the expected fall in percentage germination to very low in 1940, nil in 1941 and every subsequent year until, in 1948, the ten-year-old seed produced two sturdy plants! Storage of farm and garden seeds for a year or more is common commercial practice, but the normal 'carry-over' life of many seeds is insufficient to smooth out recurrent gluts and shortages, and it can be predicted that more experiment will almost certainly lead to the use of dried and thermostatically cooled air to increase the period of effective large-scale storage.

A number of photographs demonstrate impressively some of the points considered, and the frequent tables in the text are concise, easily interpreted summaries of the experimental results; although the serious student will note that many of them quote percentages only without actual numbers and are, therefore, not susceptible to statistical criticism. The references at the ends of the chapters appear to include only the papers by Boyce Thompson staff upon which the book is based, and might with advantage have been extended to include the more important relevant publications of other workers. A more serious limitation of this small book's usefulness may be imposed by the price, which even by to-day's standards is high. Perhaps its greatest merit is that it stimulates as well as illuminates, suggests not only how much but also how little is known, and this in one of the fields where a real contribution to knowledge can still be made by the enthusiastic individual with a minimum of time and equipment.

S. CLAY

Scientists Starred 1903-1943 in "American Men of Science"

A Study of Collegiate and Doctoral Training, Birthplace, Distribution, Backgrounds and Developmental Influences. By Prof. Stephen Sargent Visher. Pp. xxiii+556. (Baltimore, Md.: Johns Hopkins Press; London: Oxford University Press, 1947.) 25*s.* net.

FOR forty-five years scientific workers of the United States have been starred for pre-eminence by their colleagues in the reference work "American Men of Science", first by a few outstanding leaders in twelve scientific subjects, and then by those who had already been starred. This volume gives an analysis of the life-histories of those who have been starred in terms of their scholastic and academic background, and such other factors as their birthplace, month of birth, reasons for taking up a scientific career and parentage.

So far as the relative share of various American academies is concerned, this study is of no particular interest outside the United States; but a number of facts of more general interest emerge from the study. Thus we learn that more than three-fourths of the starred scientists have been employed by universities in recent years; also most starred scientists, for reasons that may well be in dispute, belong to the so-called upper classes, the highest percentage (one in seven) being fathered by Unitarian clergymen, the lowest (one in 196) by engineers. Cities are more likely to produce notable scientists than rural areas.

The statistical results given as to academic careers, however, must be considered as limited in their value when one finds among the starred physicists without a degree such a name as that of Einstein; he presumably appears in this category as having no American degree. The best chance of becoming a starred scientist seems to lie with those born in March, with January, May and October some way behind. A study of the lists in the various subjects shows no obvious omissions; but on the whole a tendency to go slightly below the level which would probably be aimed at in a similar classification in Britain. The book provides a mine of information about American men of science as a whole, which may well interest the curious as well as the serious student.

Children as Naturalists

By Margaret M. Hutchinson. Pp. 184 + 9 plates. (London: George Allen and Unwin, Ltd., 1947.) 7*s.* 6*d.* net.

MARGARET HUTCHINSON is the grand-daughter of the late Sir Jonathan Hutchinson, who founded the Educational Museum at Haslemere. In 1931 she opened her own junior school at her parents' home, Yafflesmead, near Haslemere. The school flourishes amid acres of semi-wild garden, meadow and woodland, and in this setting an enthusiast has shown how children's interest in Nature may be fostered through exploration, discovery and intimate contact with living creatures.

"Children as Naturalists" is a record of Miss Hutchinson's work and a testimony to her enthusiasm. Three general chapters on "Exploring with the Kindergarten", "Adventures with the Sixes and Sevens" and the "Study of Environment with Juniors" are followed by seven others called "The Quest for . . .", mammals, birds, pond creatures, flowers, etc. There are some useful photographs and diagrams to illustrate the text and many practical hints about the making of apparatus, as well as some of the scientific information needed by the teacher but not easily found in elementary text-books.

All this will be useful to the junior school teacher; but Miss Hutchinson's obvious advantages—small classes, large and varied grounds and the fact that she herself is a scientifically trained and passionately enthusiastic naturalist—should make her sympathetic with all teachers of Nature study in junior schools who do not reach the high standards revealed in this little book.

T. H. HAWKINS

New Biology, 3

Edited by M. L. Johnson and Michael Abercrombie. Pp. 176 + 24 plates. (Harmondsworth: Penguin Books, Ltd., 1947.) 1*s.*

THE third volume of "New Biology" maintains the standard of its predecessors. Addressed primarily to those who have a taste for scientific reading, this miscellany of essays aims at giving an up-to-date account of some aspect of biology which has excited contemporary interest. Contributions like "The Electron Microscope" and "Biological Research" by V. E. Cosslett are likely to be tough going for readers who know little about biology; but Alec Parker's article on "Beasts of Burden" will be as fascinating to the schoolboy as the *savant*. Articles on "How a Grasshopper becomes a Locust", "Forage Plants", "The Menace of the Roundworm", "Animal Life in Caves" and "Biology of Ship Fouling" indicate that the joint editors are well aware of those subjects which make popular reading.

The Genetics of Garden Plants

By M. B. Crane and W. J. B. Lawrence. Third edition. Pp. xvii + 299. (London: Macmillan and Co., Ltd., 1947.) 16*s.* net.

"CRANE and Lawrence" is now a standard text for both students of biology and for practical gardeners. Indeed, it is one of the few books which fulfil a want both for the academic specialist and for the practical man. The third edition is different in some respects from the earlier editions; parts of some chapters have been rewritten, and the subjects of xenia and polyploidy receive greater attention in special chapters. One criticism of the earlier editions was that the elementary introduction to genetics was too condensed for the non-specialist. By some clever and subtle writing the authors appear to have largely overcome this criticism in the third edition. Through fully annotated descriptions of research results, the book is an invaluable guide to the recent literature on horticultural plant genetics.

F. W. SANSOME

Territory in Bird Life

By Eliot Howard. New edition. Pp. 224 + 11 plates. (London and Glasgow: Wm. Collins, Sons, and Co., Ltd., 1948.) 10*s.* 6*d.* net.

A FRESH edition of Eliot Howard's classic book on "Territory in Bird Life" is indeed welcome, for it has long been difficult to obtain a copy of a work that every ornithologist should read. Published in 1920, it put forward the theory, supported by the author's many and painstaking observations, that the chief pivot of bird-life was territorial, nearly all birds needing to secure and hold a territory as a basis of their sexual activity and breeding cycle. This seemingly simple theory was found to have far-reaching implications, and to throw light on many aspects of bird behaviour; indeed, its importance has become more and more apparent with the passing of the years. It is good to have this new edition of so important a book.

FRANCES PITT

STUDIES OF THE STRUCTURE OF SYNTHETIC POLYPEPTIDES

By Prof. W. T. ASTBURY, F.R.S.
Department of Biomolecular Structure, University of Leeds

Dr. CHARLES E. DALGLIESH
University Chemical Laboratory, Cambridge

AND

S. E. DARMON and Dr. G. B. B. M. SUTHERLAND
Department of Colloid Science, University of Cambridge

THE recent synthesis of polypeptides from given amino-acids by Woodward and Schramm[1], following the neglected Leuchs polymerization[2], has reopened a promising line of attack on the problem of protein structure. Comparison of the properties of such synthetic polypeptides of known composition with those of proteins built of the same amino-acids should prove of great value, and in particular should help considerably in the interpretation of X-ray and infra-red data, which are still so imperfectly understood owing to the complexity of even the simplest protein. The general object of the work of which the preliminary findings are summarized below is therefore to synthesize as many as possible, first of homogeneous polypeptides (that is, those containing a single amino-acid species) and secondly of copolymers of two or more amino-acids, and then, by X-ray, infra-red and accessory techniques, to study their properties in relation to those of proteins of analogous composition.

Chemical

The polymerization of the anhydrocarboxyamino-acids was in the early cases performed in ethyl acetate in the presence of a tertiary base. Though this method has the disadvantage of giving unoriented products as white amorphous powders (the molecular weights being probably of the order of 2,000–5,000), it has the advantage that yields of the order of 50–70 per cent of polypeptide can be obtained from amino-acids available in quantities of only ½–1 gm.

With increasing availability of amino-acids, polymerizations have been carried out by the Woodward procedure, which permits in suitable cases the preparation of oriented products. The following amino-acids have been polymerized so far: glycine, sarcosine, *DL*-alanine, *L*-alanine, *L*-valine, *DL*-leucine, *D*-leucine, *L*-leucine, *DL*-*iso*leucine, *D*-*iso*leucine, *L*-*iso*leucine, *DL*-*nor*leucine, *DL*-α-phenylglycine, *DL*-phenylalanine, *L*-phenylalanine and *L*-tyrosine. Difficulty has been experienced with proline by this procedure, and this and other amino-acids are under investigation.

Marked differences have been observed between polymers from *DL*- and from optically active amino-acids, a particularly striking case being alanine, where poly-*DL*-alanine is readily soluble in water whereas poly-*L*-alanine is insoluble. In some cases the products separate with what appears to be half a molecule of structural water per amino-acid residue, which is much less readily removed from the polypeptides derived from optically active amino-acids than from those derived from *DL*-mixtures. The various mixed polypeptides have been synthesized by both the above procedures.

X-Rays

It is convenient to consider the kinds of X-r
diagrams obtained so far under the following head
(*a*) *Polyglycine.* So long ago as 1934, Meyer a
Go[3] reported on an X-ray examination of glyci
polypeptides obtained by the Leuchs reaction. The
photographs were not analysed in detail, but th
drew the conclusion that the atoms in the produ
formed when the N-carboxylic anhydride is expos
to moist air lie for the most part in planes of spaci
4·15 A. They mention, however, but do not repr
duce, another kind of diagram characterized by r
flexions at 4·4 A. and 3·45 A., that is obtained wh
the reaction is carried out in the presence of pyridin
Our diagram (Fig. 1*a*) is apparently like this latte
though we have also found indications of the form
in X-ray photographs of wool fibres, supplied
Prof. J. B. Speakman, on which a thin layer of pol
glycine had been deposited by the Leuchs reacti
carried out in ethyl acetate and water[4].

Fig. 1*a* is really a β-diagram made unfamiliar
having the backbone reflexion inside the side-cha
reflexion. It is consistent with a rectangular or ne
rectangular cell defined by $a = 4{\cdot}36$ A. (
$2 \times 4{\cdot}36$ A.), $b = \sim 7$ A., and $c = 3{\cdot}44$ A. Th
structure appears to be analogous to that worke
out by Bunn and Garner[5] for the so-called 6.6 an
6.10 nylons, and it is built presumably of sheets
chains parallel to (001). The chains in each shee
are linked by CO . . . NH linkages and their distanc
apart is 4·36 A. (cf. 4·4 A. in nylon and 4·65 A
in β-keratin).

(*b*) *Powder diagrams of the normal* β-*keratin typ*
One of the best-defined of these was obtained fro
a powder of poly-*DL*-*iso*leucine (Fig. 1*b*); but di
grams of a similar type were given also by th
polymers of *D*- and *L*-*iso*leucine, *DL*-alanine, *D*
α-phenylglycine, *DL*-phenylalanine and *DL*-*no*
leucine, and by the copolymers (glycine + *D*
alanine), (glycine + *DL*-phenylalanine), and (*D*
*iso*leucine + *DL*-phenylalanine). As with disoriente
β-keratin, β-myosin, etc., and denatured proteins, t
principal rings are 001 (side-chain), 200 (backbon
and 210. The side-chain spacing increases wit
length of side-chain, as would be expected; but it
seen also that the backbone spacing shows significa
variations: for example, glycine 4·36 A., *DL*-alani
4·59 A., *DL*-*nor*leucine 4·60 A., *DL*-*iso*leucine an
DL-phenylalanine 4·65 A., *D*- and *L*-*iso*leucine an
DL-α-phenylglycine 4·72 A. As reported in th
following section, corresponding variations are n
found in the infra-red spectra, which indicate th
the CO . . . NH hydrogen bond is similar in all th
polymers.

These combined observations are of the highe
importance, showing as they do that in spite
irregularities in chain direction caused by long
ungainly side-chains, with consequent variations
the backbone spacing between chains *as a whol*
the CO- and NH-groups of adjacent chains approa
each other always to nearly the same distance.
the same connexion it should be mentioned that the
are indications from other spacings that the effecti
length per residue in polyglycine and poly-*D*
alanine may be a little greater than the maximu
(3½ A. in silk fibroin) observed in the fibrous protein
and this recalls Corey's estimate[6] from X-ray cryst
data on glycine, alanine and diketopiperazine th
the effective length per residue in a *completely* ex
tended polypeptide chain should be 3·67 A.

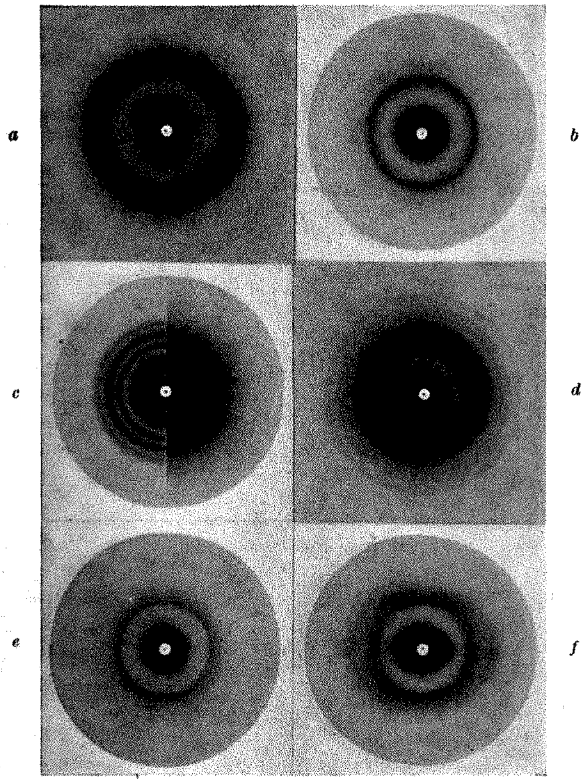

Fig. 1. (*a*) Polyglycine; (*b*), poly-*DL*-*iso*leucine; (*c*) comparison of poly-*DL*-alanine (right) with poly-*L*-alanine (left); (*d*) poly-*L*-phenylalanine; (*e*) poly-*D*-leucine + *DL*-phenylalanine, X-ray beam perpendicular to film; (*f*) poly-*D*-leucine + *DL*-phenylalanine, X-ray beam parallel to film

The powder diagram of the copolymer (*DL*-*iso*leucine + *DL*-phenylalanine) shows a strong side-chain reflexion of similar spacing to those of the polymers of the separate constituents; it is noteworthy, however, that no definite side-chain reflexion, but only a haziness, is seen in the diagrams given by (glycine + *DL*-alanine) and (glycine + *DL*-phenylalanine).

(*c*) *Abnormal powder diagrams.* Some of the powder diagrams discussed under (*b*) show unfamiliar features not yet fully accounted for; but on the whole it seems correct at the moment to regard them all as belonging to the type of β-keratin, that is, as structures built up by superposing flat or almost flat polypeptide grids so that the general directions of the side-chain and backbone linkages stand perpendicular, or almost perpendicular, to each other. All these normal β-diagrams, except those from poly-*D*- and poly-*L*-*iso*leucine, were obtained from *DL*-polymers and copolymers. A number of products, however, from *D*- or *L*-acids alone have been found to give diagrams showing a systematic peculiarity: there is notably a reflexion at about 5·2 A., and to explain the accompanying reflexions it would appear that it is this spacing, and not the normal backbone spacing, that has now to be taken perpendicular to the side-chain spacing. The counterpart of the normal backbone reflexion is present, too, but its spacing is now 'diagonal' (see Fig. 2); so that what was 200 in the *DL*-diagram becomes 201 in the *D*- or *L*-diagram, while the normal 210 becomes 211 (see Fig. 1*c* for a comparison of the diagrams of poly-*DL*- and poly-*L*-alanine, and note that the strong reflexion at 5·28 A. in the latter is completely absent from the former).

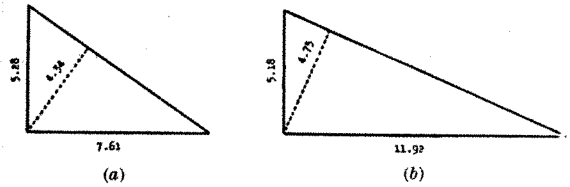

Fig. 2. (*a*) Poly-*L*-alanine: (*b*) poly-*L*-phenylalanine

This kind of modification has so far been observed with the polymers of *L*-alanine, *L*-valine, *L*-phenylalanine, and probably *L*-tyrosine; and poly-*DL*-leucine shows it with an additional complication that we have not yet elucidated. The diagram given by poly-*L*-phenylalanine (Fig. 1*d*), consisting of at least fifteen clear reflexions, is particularly striking: most or all of the reflexions can be explained on the basis of a rectangular cell of dimensions: $a = 2 \times 5{\cdot}18$ A., $b = 2 \times 3{\cdot}33$ A. (presumed amino-acid spacing), and $c = 11{\cdot}92$ A. (side-chain spacing).

The interpretation of these homogeneous polymers of *D*- or *L*-acids alone thus seems to require a new kind of side linkage in place of the backbone linkage met with hitherto. The new spacing is greater than the usual backbone spacing, and a possible explanation would be that it incorporates perhaps a water molecule between CO- and NH-groups of adjacent main chains, which are apparently still in the extended configuration.

(*d*) *Films.* For the present we are able to report only limited progress in making films or other oriented preparations of synthetic polypeptides. Traces of orientation could be detected in a pseudo-film of poly-*D*-leucine, and quite a rich, partially oriented diagram was obtained from a very brittle film of poly-*L*-tyrosine. This latter diagram has not yet been worked out satisfactorily.

The outstanding single set of results with films comes from preparations of the copolymer (*D*-leucine + *DL*-phenylalanine). It was first reported by Brown, Coleman and Farthing[7] that films of this copolymer, prepared by the method of Woodward and Schramm, gave, when photographed with the X-ray beam parallel to the surface, a quasi-fibre diagram resembling the well-known α-diagram given by the unstretched forms of the keratin-myosin-epidermis-fibrinogen group of fibrous proteins[8]. We have confirmed this finding (with films deposited on glass) and have made some further advances. Two of our photographs are illustrated in Figs. 1*e* and 1*f*, the former taken with the beam perpendicular to the film and the latter parallel. The film used for Fig. 1*f* was obtained from the inside of a glass tube in which a benzene solution of the copolymer (ratio 1 : 1) had been evaporated at about 70° C.: the orientation is the best so far produced in a film.

The following points may be noted. (1) The spacing of the prominent meridional arc, which so strongly recalls that of the α-diagram, is $5{\cdot}2_3$ A., and not $5{\cdot}1_4$ A. as found in α-keratin. (2) The intense central oval in Fig. 1*f* is foreign to the α-diagram: on the meridian its spacing is 11·9 A. (practically identical with the presumed side-chain spacings found in the powder diagrams of poly-*L*-phenylalanine and poly-*DL*-leucine), and on the equator $10{\cdot}3_7$ A. There is also a weak meridional reflexion at 7·4 A. (3) The central oval in Fig. 1*f* becomes a circle of spacing 11·9 A. in Fig. 1*e*: the $10{\cdot}3_7$ A. spacing is therefore preferentially oriented perpendicular to the film.

Pending the outcome of experiments, which are in progress, to prepare genuine fibres, it would be premature just now to attempt any detailed interpretation of this most interesting diagram. None of the usual methods of transforming α- into β-proteins has yet proved effective in changing it into one of the orthodox β-type, and in view of the diffraction peculiarities mentioned it is very questionable indeed whether it is a case of a true α-structure: rather does it recall the polymers of *D*- and *L*-acids described under (*c*), which appear to be in the extended configuration, but with a new kind of side-linkage of spacing of about 5·2 A. Incidentally, the 1 : 1 ratio of the constituents of the copolymer is not specific, since we have obtained a powder diagram of a similar type with the ratio 5 : 3.

(*e*) The investigation is being continued along the lines of further combinations of amino-acids and preparations oriented if possible as fibres. Exact knowledge is also being sought on the extent to which some of these synthetic polypeptides may combine with water, and the bearing this may have on the occurrence or not of the supposed new side-linkage of spacing about 5·2 A. If it should turn out that such a type of spacing includes also that found in the film diagram given by the copolymer (*D*-leucine + *DL*-phenylalanine), it is nevertheless still on the cards that it may lead to a proper understanding of the characteristic meridional arc in the true α-diagram; for it is to be remembered that the postulated α-fold may be thought of as stabilized by what amount to *side*-linkages—not simply between adjacent main chains, of course, but between short consecutive lengths of one and the same main chain[9].

We are also investigating possible cases of polymorphism among the products obtained from base-catalysed and uncatalysed polymerizations.

The X-ray photographs discussed above were taken by Mr. E. Beighton, to whom we should like to express our thanks.

Infra-Red

The general resemblance between the near infra-red spectrum (between 3,500 and 1,500 cm.$^{-1}$) of a synthetic polypeptide and that of any protein molecule has already been remarked[10]. This arises from the fact that the main absorption bands in this region of the spectrum are due to characteristic vibrations in the —CO—NH— group and to CH-stretching frequencies. As we proceed farther into the infra-red (that is, to the lower frequencies between 1,500 and 700 cm.$^{-1}$), many of the absorption bands are due to characteristic vibrations of the hydrocarbon side-chains of the various amino-acids. It was suggested[10] that differences in this region of the spectrum might be made the basis of a method of identifying an amino-acid residue in a protein, provided sufficient data were available on the spectra of polypeptides synthesized from various amino-acids. We have accordingly examined the spectra of a representative selection of synthetic polypeptides from various amino-acids. However, we have not confined our attention to the region of low frequencies but have also studied the high frequencies of the —CO—NH— group, since it is here that variations in the hydrogen bonding which plays such an important part in the structure of proteins may be most readily followed.

(*a*) *Low-frequency region*, 1,500–700 *cm.*$^{-1}$. The spectra of powders of the polymers of glycine, *L*-alanine, *DL*-alanine, *L*-phenylalanine, *DL*-phenylalanine, *L*-leucine, *DL*-leucine, *L*-*iso*leucine, *DL*-*iso*leucine, *DL*-phenylglycine and *L*-tyrosine are all different from one another and quite characteristic in the region 1,500–700 cm.$^{-1}$. The differences between the spectra of polymers made from *D*- or *L*-forms of any acid and the spectra of the corresponding *DL*-forms are small compared with the differences between the spectra of polymers of different amino-acids, but are none the less quite real. We may therefore take it as established that each amino-acid polymer has characteristic frequencies, and the next question is whether these persist in copolymers made from two or more different amino-acids.

The answer to this is not quite so clean-cut and is less certain in that the number of copolymers so far studied is small. The spectrum of a (glycine + *DL*-alanine) copolymer was found to correspond remarkably closely to the 'addition spectrum' of the individual polymers, showing that there are certain bands which are characteristic for each amino-acid even when copolymerized. The spectrum of a (glycine + *DL*-phenylalanine) copolymer was also found to resemble closely the corresponding 'addition spectrum', certain bands of the individual polymers being clearly distinguishable, although a few of the others either disappeared or shifted in position in the copolymer. In this case, these differences were used to follow the progress of the copolymerization, samples of the copolymer being withdrawn for spectroscopic analysis at various stages. The copolymer (*D*-leucine + *DL*-phenylalanine) was examined both as a film and as a powder. The two spectra were virtually identical, and again many of the bands of the separate polymers were easily recognizable in the copolymer. There were, however, certain marked differences, and in particular this copolymer had a fairly strong band at 795 cm.$^{-1}$ which was not present (at least in comparable intensity) in either of the individual polymer spectra.

The conclusion to be drawn from these results is that for each amino-acid there are certain frequencies which persist in copolymers and may therefore be expected to persist in proteins containing these amino-acids. Such frequencies must clearly be due to the hydrocarbon chain in the amino-acid, and in a few cases assignments (based on the interpretation of hydrocarbon spectra) have been possible, although these need not be discussed here. Certain other

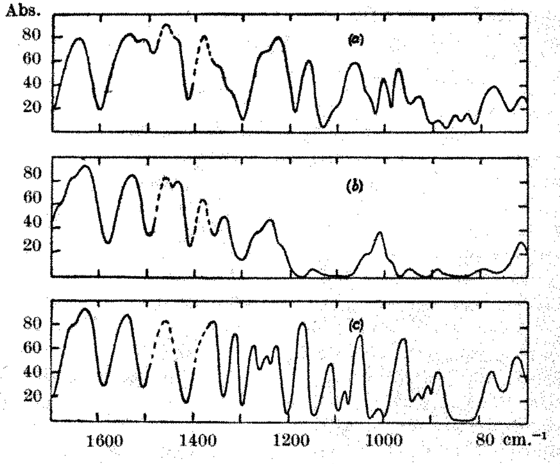

Fig. 3. Infra-red absorption spectra in the region 1,700–700 cm.$^{-1}$ of: (*a*) Silk fibroin (fibres immersed in nujol); (*b*) polyglycine; (*c*) poly-*L*-alanine (powders suspended in nujol). Broken lines indicate absorption due to nujol

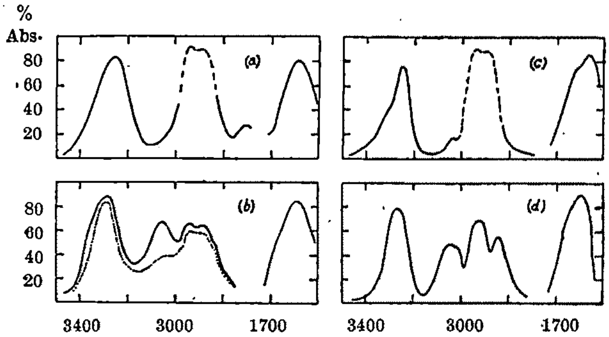

Fig. 4. Infra-red absorption spectra in the regions 3,500–2,800 cm.$^{-1}$ and 1,700–1,600 cm.$^{-1}$ of: (*a*) silk fibroin (fibres immersed in nujol); (*b*) tropomyosin film (—— film prepared at room temperature, ... after pressing in steam); (*c*) poly-*L*-alanine (powder suspended in nujol); (*d*) film of *D*-leucine + *DL*-phenylalanine copolymer (ratio 1 : 1).

Broken lines in (*a*) and (*c*) indicate absorption due to nujol

frequencies in this range appear in the simple polymer spectra but not in the copolymers and *vice versa.* The assignment of these is not yet clear, but they most probably arise from vibrations associated with the bonds involved in the link between the side-chains and the backbone.

We have successfully applied the above results to the identification of amino-acids in a protein, and believe that this is the first occasion on which this has been done without decomposing the protein molecule. In Fig. 3 are given the spectra of silk fibroin together with those of polyglycine and poly-*L*-alanine. The appearance of certain of the bands in the synthetic polypeptides in the natural protein is so obvious that it does not require detailed comment. It need scarcely be added that this method is unlikely to be successful except in very favourable circumstances for detecting amino-acids which are present in small proportions, although we might add that we believe that we have also identified tyrosine in silk fibroin. The amino-acid analysis of a complex protein by this method is, of course, quite impracticable. What we consider much more important is that further investigations along these lines with copolymers of controlled structure and composition may throw light on the arrangement of the amino-acids in some of the simpler proteins.

(*b*) *High-frequency region,* 3,500–1,500 *cm.*$^{-1}$. The NH- and CO-stretching frequencies near 3,260 cm.$^{-1}$ and 1,640 cm.$^{-1}$, respectively, are essentially the same in all the polymer and copolymer spectra, whether from *DL*-, or *D*-, or *L*-acids. This means that the CO . . . NH hydrogen bond must be similar in all the polymers. At first sight this seems to conflict with the X-ray evidence that the backbone spacing varies from 4·36 A. (in polyglycine) to 4·72 A. (in poly-*DL*-α-phenylglycine), since a variation of this magnitude in a distance controlled by the CO . . . NH-linkage would certainly lead to a large variation in the NH-stretching frequency. If the explanation of this apparent anomaly advanced in the preceding section be correct, it underlines an important distinction between the structural information provided by X-ray and infra-red methods in problems of this kind, the former giving a diffuse overall picture of the structure from which hydrogen bond distances are deduced, whereas the latter gives a direct measurement of the length of the hydrogen bond but no direct information on the structural pattern unless polarized radiation is used on highly oriented films.

Although the CO- and NH-bands are similar in all the polymers, there are indications in many cases of some fine structure on the high-frequency side of each band. This has not yet been fully investigated, but it must mean that in many polymers *slightly* weaker hydrogen bonds exist in addition to the usual CO . . . NH-bond associated with the backbone linkage. This might arise from distortion of the backbone spacing in accommodating the side-chains, and may even be connected with the fact that films of certain polymers are harder to produce than others. Alternatively, it may indicate another type of hydrogen bond arising from some other feature of the structure yet to be elucidated.

That more than one type of hydrogen bond can exist in these polymers and in proteins is clearly demonstrated by the occasional occurrence of an NH-stretching band near 3,040 cm.$^{-1}$. This band is very prominent in the spectrum of the copolymer film (*D*-leucine + *DL*-phenylalanine), but is either absent or comparatively weak in the spectra of all the other polymers (Fig. 4). The fact that the X-ray evidence at first sight indicated an α-configuration for this copolymer seemed to be consistent with the fact that this 3,040 cm.$^{-1}$ band is present in the spectrum of the α-form of tropomyosin but weakens very markedly when the tropomyosin is converted to the β-form by pressing between plates in steam[11]. Moreover, we find this band is absent in the spectrum of silk fibroin known to have a β-configuration (Fig. 4). However, what seemed a striking correlation between the presence or absence of this band and the existence of α- or β-configurations breaks down completely when one considers the spectrum of nylon. This band is present in nylon, which has been shown by Bunn and Garner[5] to have a β-configuration. All we can say at present, then, is that there are at least two very distinct types of hydrogen bonding present in many proteins and in some protein-like polymers (notably nylon and *D*-leucine + *DL*-phenylalanine), and that this bond appears to be connected in some way with folding of the polypeptide chain.

In this connexion two minor but important points should be mentioned. The first is that there is no doubt whatever that the 3,040 cm.$^{-1}$ band is due to an NH-frequency, the most direct proof being that we find it is absent in the spectrum of fully methylated nylon. Incidentally, we have investigated this very interesting band extensively in simpler amides, but a full account of this work must be given elsewhere. The second point is that it is just possible that the weakening of the 3,040 cm.$^{-1}$ band observed by pressing tropomyosin between plates in steam may arise from a known orientation effect[11]. This is being investigated further by using polarized radiation.

In the preceding section on X-ray diffraction it was noted that marked differences occurred in many cases between the patterns given by *D*- or *L*-polymers and those given by *DL*-polymers. Little or no correlation has so far been found between these results and the infra-red spectra of the corresponding compounds. In particular, no clear evidence of water molecules in the *D*- or *L*-polymers has yet been found. Although the weak band on the side of the main NH-band at 3,240 cm^{-1}. in poly-*L*-alanine might possibly be due to water, this extra band was not found in poly-*L*-phenylalanine.

The final elucidation of many of the above results cannot be given until much more experimental work has been carried out, particularly on oriented films with polarized radiation.

We are very much indebted to Dr. K. Bailey for the specimen of tropomyosin, and to Dr. G. R. Tristram for the specimen of silk fibroin.

COLOUR AND COLOUR VISION IN ANIMALS

On September 13, a series of papers on colour and colour vision in animals was read before Section D (Zoology) of the British Association. The object of the discussion was to consider recent results on the physiology of colour production and appreciation in animals, and the bearings of these results on theories of the biological uses of colour—in protective resemblance, mimicry, warning coloration and other ways.

The discussion was opened by Dr. R. J. Pumphrey with a paper on the distribution of colour perception in the animal kingdom. He first pointed out the difficulties in the way of obtaining experimental proof of the presence of colour discrimination in animals, which can tell us of their perceptions only by their behaviour. Besides this, colour is itself a difficult experimental subject; it is never easy to exclude other stimuli such as those of variations in brightness—to the animal and not to us—and, if the animal's spectral range differs from ours, control of wave-lengths outside our visible range is needed. Further, the animal's behaviour will be influenced only if perception of the colour is important to it; and changes of behaviour can be interpreted only if the animal behaves in a consistent and intelligible manner, and is not disturbed by other stimuli or by its own nervous state.

Nevertheless, colour perception has been established beyond reasonable doubt in some insects and, among vertebrates, in some bony fishes, reptiles, birds and the primates. Dr. Pumphrey believes its presence in the Crustacea and Cephalopoda unproved. In the rest of the animal kingdom there is no sound evidence of its presence, and in many groups failure to demonstrate it makes its presence unlikely.

Animal colour perception, where it exists, resembles our own rather closely. There is no evidence of dichromatism as a primitive condition; but this may be due to inadequate experimental methods. Some birds and fishes may have a closed colour circle, that is, they may fail to distinguish red from violet, and may not recognize extra-spectral purples. Many insects see much farther into the ultra-violet than we do, and can distinguish ultra-violet from the parts of the spectrum visible to us. Insects see colours in weak light so long as they are able to see at all; in this they are in contrast with vertebrates, whose perception of colour fails in weak light. At night vertebrates have no colour sense; all nocturnal vertebrates are colour-blind.

Dr. R. W. Pickford spoke on the varieties of colour vision in man. Total colour-blindness is rare. The most usual abnormalities are deuteranopia, in which red and green are confused, looking yellowish, and protanopia, in which there is also a great darkening of the red end of the spectrum. In anomalous colour vision, discrimination of colours is retained; but either red or green may be greatly weakened as compared with the normal. With red anomalous vision there is in some cases also darkening of the red end of the spectrum. All are Mendelian recessives and sex-linked, except that in total colour-blindness the linkage is partial. About 7 per cent of men show red-green colour-blindness.

In addition to these major defects, minor variations from normality occur. The commonest is a weakness of blue discrimination; those with it tend to confuse greenish-blues, such as Cambridge blue, with green. Yellow weakness also occurs, and leads to confusion of yellow with white. These minor defects are not sex-linked.

Dr. M. G. M. Pryor discussed the conditions under which colour in an animal can be certainly said to be adaptive. Adaptiveness implies that the colour has selective value and that in the absence of selection the colour would be different from what it now is. To prove adaptiveness, we therefore need to know the natural non-adaptive colour. Often this is white, as in many cave animals that live in the dark, but not always so. Some cave insects are black or brown, the colour of the dark tannin with which their chitin is hardened. Dark colour in an insect therefore needs no 'adaptive' explanation. Whiteness in an insect is more unusual and is often due to a layer of unhardened—and undarkened—chitin outside the dark chitin within it.

Brilliant colours are not always adaptive. Golden colour, as in the pupa of the peacock butterfly, may be due to the natural colour of the chitin. Brilliant interference colours may be due to a number of thin, transparent films of chitin of the right thickness. Often these colours occur where they cannot be adaptive—inside the cast skins of bluebottle pupæ, or in the bristles of the sea-mouse which lives buried in mud. The blues and greens of the outer surface of bluebottles and dung-flies are due to interference at the layer of wax that covers the chitin.

Some of these colours may have been exaggerated or otherwise modified adaptively, but a knowledge of what the colours would be without adaptation and of the manner in which they are produced is necessary if we are to assess the adaptive element in them.

Dr. G. S. Carter discussed, in the light of the facts given by the previous speakers, the conditions under which colour as seen by other animals may be of importance in the biology of an animal. First, it is clear that not all animal colour has this importance. To the categories of non-significant colour already mentioned may be added much colour in lower invertebrates, such as many sea-anemones and sea-urchins, which have few enemies. This is at least true of the many species that do not catch large animals as prey. Much colour in physiological substances is non-significant—blood pigments, excretory substances. Some pigment may be used as defence against light, as probably the black pigment of many desert animals, but is not related to the animal's contacts with other animals.

Value in colour in the biological environment implies that the animal seeing it has colour vision. As Dr. Pumphrey showed, only some arthropods and some vertebrates have been shown experimentally to have this faculty. Perhaps some cephalopods should be added, on the evidence of their natural behaviour and not on experimental results. Such evidence may be as conclusive as the experimental.

Wherever colour is of value in the interactions of animals, except in the rare cases where the stimulus is a simple flash of colour, pattern appreciation as well as colour perception is necessary in the observing animal. It is therefore not surprising that a colour sense and an image-forming eye are associated in animals, for pattern appreciation is the characteristic of image-forming eyes.

In recognition of an animal by another, two distinct components of the process of recognition must be distinguished. First, the animal must be recognized as a discrete object on its background. This is prevented by the various forms of camouflage. Secondly, the animal must be recognized as of a particular kind—for example, of a kind suitable as food. To understand how the second can be prevented by adaptation in colour and pattern, we need to know how animals recognize the kinds of objects.

In much of their behaviour, animals, even such complex animals as birds and insects, recognize the kinds of objects not by an aggregate of many characters, as we do, but by one, or at most a few, 'valent' characters, such as the smell, shape, colour, pattern or type of movement. Not all animal behaviour is of this simple type; but so far as it is, a resemblance that includes the valent characters will be effective, although in other characters there is no resemblance. But if an animal is exposed to predators of many species, a detailed and complicated resemblance may be built up by combining the different valent characters required by the various species. We can thus see how the astonishingly accurate resemblances we find in Nature may have originated from very partial resemblances which, in spite of their incompleteness, would still have had some value. G. S. CARTER

PHYSIOLOGY OF LACTATION

AT a joint meeting of Sections M (Agriculture) and I (Physiology) of the British Association, held at Brighton on September 14, recent research on the physiology of lactation was discussed. Prof. H. Hartridge, president of Section I, was in the chair.

The discussion was introduced by Prof. H. D. Kay (National Institute for Research in Dairying, Shinfield) who said that in view of the importance of lactation both from the human and from the industrial points of view, it is remarkable that the physiology of the mammary gland had, until recent years, received so little attention. During the past dozen years, however, knowledge has advanced substantially as regards the endocrine control of mammary development and of milk secretion, including the artificial induction of lactation in the virgin or barren animal, the hormonal inhibition of lactation, the cytology of the gland in relation to function and the 'let-down' of milk as a conditioned neuro-hormonal reflex. The biochemistry of milk secretion, including both glandular metabolism and the factors affecting milk composition, have also undergone active study. Advances in knowledge of the neuro-hormonal mechanisms by which the mammary gland is controlled are already beginning to influence both milking technique and also clinical methods of dealing with problems of human lactation.

There is a very rapid blood-flow through the actively secreting gland, and a large consumption of oxygen. The respiratory quotient of the secreting tissue is, in the intact animal, well above unity, and in surviving slices of tissue suspended in a nutrient solution, figures as high as 1·5–1·6 have been obtained by T. H. French, suggesting fat formation from carbohydrate. A major difficulty in recent biochemical studies in the intact animal is the uncertainty of the extent of error due to lymph drainage, and all findings depending on arterio-venous changes must be interpreted very cautiously.

The practical significance was pointed out of the recent work of Dodd and Foot at Shinfield, who have found that more than 50 per cent of the fat originally present in the secreted milk in the bovine udder is *not* removed during the ordinary process of milking. Very recent findings which indicated that milk composition might be influenced by naturally occurring œstrogens present in young grass and clover were also described. The relationship between the texture of the teat and liability to udder infection, established in the last few months by J. I. Taylor at Compton, was mentioned as a new factor that seems of importance in buying or breeding a cow.

Mr. K. C. Richardson (University College, London) described with the aid of slides some of the results of his recent studies of the cytology of the mammary gland in relation to function. The milk-secreting alveoli are not usually spherical, but are rather elongated structures, the secreting cells of which show great changes in shape and size at different stages in the secretory cycle. The synthesized milk constituents pass from these cells into the alveolar lumen by recurrent rupture of the cell membrane. Whether or not there are nerve fibres ending in the secretory tissue is as yet unsettled, the available histological technique being insufficiently specific. He discussed the possible mechanism of 'let-down'. There is no doubt that during 'let-down' active pressure is brought to bear on the milk which has been secreted into the alveoli. Smooth muscle, though present in the mammary gland, is neither in the right places nor in sufficient quantity to make any serious contribution to the 'let-down' phenomenon. There are no sphincters on the ducts emerging from the lobules. However, as a result of a recent advance in histological technique, clear evidence has been obtained of the abundant presence in the gland of myo-epithelial cells, the large nuclei of which are usually to be found between the alveolar secreting cells and the basement membrane, and the processes of which can be shown to extend over the outer surface of each alveolus. Convincing histological evidence was brought forward by Mr. Richardson that these cells can and do contract at 'let-down'; the basket structure, tightly embracing the distended alveolus before 'let-down', does not become flaccid when the milk has been forced out and the alveolus diminished in size, but remains taut.

Dr. S. J. Folley (National Institute for Research in Dairying, Shinfield) briefly mentioned three stages in the history of research on the control of the mammary gland. In the earliest stage, the control appeared to be mainly of neural origin; but the establishment of the fact that mammary tissue could actively secrete when removed from any nerve connexion with the rest of the body, together with experiments showing the great importance of hormonal influences on the gland, led for a time to mammary physiology becoming almost a branch of endocrinology. The more balanced, modern view that neural and hormonal influences must be considered together in obtaining a satisfactory picture of the growth and function of this gland is now supported by increasing evidence. Thus the sucking stimulus apparently causes reflex secretion of prolactin by the anterior pituitary, by a pathway not yet understood, and is of importance not only in initiating milk secretion but also in maintaining it and in indirectly preserving the structural integrity of the milk-producing tissue.

The milk already secreted by the gland is, before suckling or cowshed milking, present in two portions. One can be obtained from the gland cisterns in the cow by careful cannulation (avoiding nervous stimulation); the other portion of the milk is more tenaciously held in the smaller ducts and capillaries and has to be forced out by an active (but involuntary) process. This latter process, 'let-down', though activated by a posterior-pituitary hormone, is in the intact animal a nervous reflex that can become conditioned, and is easily inhibited, both in the bovine and in the human. In the denervated udder, or in the isolated, perfused gland, 'let-down' can, however, be readily brought about by the introduction of oxytocin into the circulating blood. There is no evidence for the 'erection' of udder tissue by engorgement with blood; the true nature of the contractile tissue in the gland, hitherto uncertain, has now been established for the first time by the experiments just described by Mr. Richardson.

Dr. K. L. Blaxter (Hannah Dairy Research Institute, Ayr) described recent applications to dairy cattle of hormonal treatment for initiating or increasing milk secretion. Widespread treatment of thousands of normal animals presupposes a large supply of endocrine preparations, and for this reason synthetic sources of hormones are of the greatest potential use; synthetic œstrogens and iodinated proteins containing thyroxine can now be made on a large scale.

Lactation in barren cows and virgin heifers can be induced in a large proportion of such animals, though not, apparently, in all, by administration of synthetic œstrogens of the stilbœstrol type. There is great individual variability in the quantitative response to such treatment, for reasons that are not yet clear. Another practical handicap is that the treated animals are 'on heat' during the whole period during which the œstrogen is being administered; this leads, if the treated animals are allowed to run with other cows, to coital mimicry and the serious risk of pelvic fracture, since the œstrogen causes relaxation of the pelvic ligaments.

The feeding of iodinated proteins to lactating cows induces an increase in milk production, the magnitude of which depends on the dose given to the cows. A reasonable practical increase, say, of 20–25 per cent, can readily be obtained. Experiments were described showing the effect of such treatment on both milk-yield and composition and on the condition and behaviour of the animals. The milk obtained after feeding iodinated protein shows no thyroxine-like effect when taken in quite large quantities by human consumers, though its iodine content is increased. From the economic point of view, the value of the extra milk produced is considerably greater than the cost of the iodinated protein plus the extra feeding stuffs required. The margin of safety between an optimal dose and one which causes breakdown in the cow is not sufficiently large to allow the material to be used by other than competent farm staff. So far, in experiments lasting several months during which carefully controlled quantities were fed, there were no bad effects on the cow's health either at the time or in the next lactation; but until long-range experiments, now in progress, are completed, iodinated protein feeding cannot be regarded as a practical method for increasing the nation's milk supply.

Dr. Gaines (Glasgow) showed, by lantern and microscope, recent results of histological examination of human nipples. There are very abundant nerve endings in the nipple, many of them associated with smooth muscle cells, and associated with the erection that takes place after stimulus. The sucking stimulus of the infant is remarkable—the suction on the nipple could be as great as 100 or even 200 mm. of mercury. So far, though their presence had formerly been assumed in the nipple, no Meissner corpuscles had been found.

A discussion followed the papers referred to above.

PRIMITIVE TECHNIQUES, AGRICULTURE AND ECONOMIC ORGANISATION

PRIMITIVE techniques and their influence upon economic organisation was the subject of a discussion in Section H (Anthropology) of the British Association on September 10 at Brighton. Mr. R. U. Sayce, president of Section H, was in the chair.

The discussion was opened by Mr. Adrian Digby, who laid stress on the importance of the time factor. The study of society and the study of technology have, he said, been drifting apart under the influence of the functional school. The welter of closely integrated, not to say tangled, data with which social anthropologists have to deal has led those with leanings towards sociology to jettison the study of material culture as of least value to their particular interests and to specialize in social structure as a way out of their difficulties. On the other hand, those interested in material culture have paid more attention to the 'anatomy', as it were, than to the 'physiology' of their material. But there is a very close relation between social organisation and the manner in which people set about satisfying their needs in life.

There are, said Mr. Digby, six essential factors necessary to the daily life of any community: namely, (i) food, (ii) clothing, (iii) housing, (iv) fuel, (v) social integration for the distribution of the results of labour, and for security, and (vi) social integration for emotional and intellectual satisfaction. Under this latter head he included religion marriage and relaxation. The relative importance of these six factors would vary according to circumstances, but the growth of any one in importance, or in time occupied, would be at the expense of some other factor or factors of the six enumerated. This he illustrated by reference to the Australians, whose dependence on hunting and food-gathering, a slow method of producing food, leaves relatively little time for anything else except the elaborate rituals which satisfy the sixth need in their case and were also partially or largely directed to improving the food supply. With the Australians he contrasted the modern Maya, who, cultivating maize on the *milpa* system (analogous to the dry cultivation of rice), can with 190 days work in the year produce nearly twice as much maize on a ten-acre plot as a family of five needs for consumption, and have 175 days left for the other five basic needs. These figures, derived from Steggerda, represent an economy that relies upon steel tools; the ancient Maya relied upon stone ones. Their production would therefore be much less, but one could still assume that they produced sufficient food to give them, without surplus, a similar 175 days of leisure. With that they built themselves ample wooden dwelling-houses, developed textile and ceramic arts to a high degree, attained great intellectual achievement in mathematics and astronomy, and constructed elaborate ceremonial centres such as Copan and Tikal. The bulk of the population seem to have been peasant farmers; but the life occupation of each child was predetermined by a system of casting horoscopes—direction of labour by divine sanction which any bureaucratic government might envy to-day. If more time had been required for food production, all these other developments could not have occurred in the same degree; greater or less stress on any one of these would have had a major effect on their culture as a whole. No general rule can be deduced owing to lack of data from a quantitative point of view.

In the case of techniques other than agriculture, data are even scantier. Thus in West Africa men and women use different looms with entirely different technique of weaving; the differentiation is not based apparently on any physiological grounds; the reasons for it may be historical or psychological; but, without data as to time, labour and production, it is impossible to tell how these different methods of weaving fitted into the social and economic organisation of the people who practised them. New ools may create demands requiring a departure from raditional practice; new methods may involve hanges, economic or social, which social or psychoogical considerations are unlikely to invalidate. Changes in material culture tend to be adopted far more rapidly than social changes; but the impact of Western civilization on the social side is none the less reat for being exercised through material objects.

The corrective element to the unfortunate centriugal tendencies of modern anthropology is to be ound in the study of the time factor as applied to all productive techniques and the labour forces available. It was for the more careful study, by eld workers, of technical processes, and especially of he time and labour required for them, that Mr. igby particularly pleaded.

Mr. G. I. Jones followed Mr. Digby with a paper n the north-eastern tribes of south-east Nigeria, known to their neighbours as the Ndi Ogu Uku—the people of the Big Hoe. These tribes have a social nd economic structure very different from their eighbours, and Mr. Jones suggested that this is rimarily and mainly due to the use and development f their superior agricultural tool. The normal Ibo ibal structure lays emphasis on concentration and consolidation into compact, and therefore politically safe, communities subsisting on hoe cultivation, but using the normal small hoe at the end of a crook-shaped handle. The Ndi Ogu Uku, however, use a hoe with a blade of similar shape, but much larger and hafted into a heavy club-shaped handle. This implement makes it possible to extend yam plantations rapidly over a much larger area; thus shifting the basis of economic importance from labour to land. Other Ibo tribes also have a colonizing system; but, apparently owing to the slower rate of cultivating and to the concentration of populations, colonies once thrown off tend to become independent units, with their own separate communal life, at a distance from the parent community. In the case of the Big Hoe people, however, their rapidity of expansion in uncultivated land has led to the throwing out of colonies on a periphery of perhaps twenty miles or more without any break in family or political organisation, the younger members of a family retaining an interest in the parent village site and sending back colonists to replace elder members of their line in tribal councils and in family properties as places fall vacant. The peripheral communities of Big Hoe Ibo may be numerically weak in themselves, but the retention of close integration with their parent villages provides the reliance on numbers necessary to political security; while the use of the big hoe makes possible a rapid territorial expansion and a rapid increase in population and in organised political power. The Ibo communities therefore illustrate the very marked change in social and economic structures which can be brought about by a very minor change in material culture.

In the short discussion that followed Mr. Jones' paper, it was made clear that the use of the big hoe among the Ibo seemed to have developed gradually and was not attributed to any particular invention or to any given 'culture hero'; the other tribes using the traditional small hoe professed inability to use the big hoe, but this was due rather to the absence of the tradition than to any physical incapacity. Prof. Gordon Childe congratulated Mr. Digby on having illustrated the true function of functionalism in anthropology.

Prof. J. H. Hutton followed with a comparison between the cultivation of wet and dry rice in the Naga Hills of Assam. Food was clearly the most important of Mr. Digby's six basic needs, since without it the others would not arise; the available leisure, and the surplus food, after the needs of the community were assured, would vary, and their utilization would vary, and different patterns of society would be determined accordingly. The common physical affinities and common ecological background of the Naga Hills has made possible the elimination of many variables and therefore a valid comparison between the two contrasting economies. The hilly terrain had probably led to some sort of terracing even for dry crops; rice was later in time than millet and had possibly been first introduced as an irrigated crop purely, and used also as a dry crop afterwards. Terraced irrigation on the very steep hillsides involves very long-term commitments and a much greater initial effort than dry cultivation, and the occupation of permanent village sites is implicit. But the periodic labour is very much less than in dry cultivation, and much greater periods of leisure are made possible as well as a generally greater economic surplus. Only when very long-standing forest is felled for dry rice is the yield greater than from irrigated fields, and even then the labour of felling is greatly enhanced and leisure correspondingly restricted.

Prof. Hutton illustrated the point by describing the comparative agricultural years of the Angami and Sema Nagas, emphasizing the much more continuous labour of the latter on their dry fields, and the much greater leisure enjoyed by the former as well as a greater economic surplus from their irrigated terraces. This gave the Angami a much richer and more colourful social life, since more leisure and wealth are available for the fifth and sixth needs. Moreover, a concentration of population is possible, with consequent political influence and stability. He suggested further that the absence of leisure in dry cultivation may be a contributory factor in the specialization of village industries like pot-making and weaving, which (in the Naga Hills) are often alternatively practised in one village and *taboo* in a neighbouring one, and may thus have contributed to the formation of occupational castes. He described the difficulty, enhanced by ritual considerations and by the absence of perennial forest, of effecting a change from a dry to a wet economy; but when once achieved, such a change leads to much greater independence on the part of individual villagers and tends to reduce the power of individual chieftains.

Dr. E. R. Leach, who followed with a paper on dry rice cultivation in Burma and Borneo, took a very different view from Prof. Hutton. He repudiated any general dichotomy in the wet and dry cultivation, regarding them as complementary rather than alternative methods of agriculture, and treating the administrative condemnation of dry rice cultivation as based on incomplete knowledge and mere prejudice; advocates of a change from dry to wet, he said, ignore problems such as that of redistribution of labour involved in the change. Dr. Leach had worked out a most detailed analysis to compare the labour and results of three methods of agriculture: 'slash and burn' methods of cultivating on dry ground, cultivating with the hoe for dry or wet rice, and cultivating with the plough. The difference between them, he said, is more fundamental than that between dry and irrigated rice. His general conclusion was that the cultivation of dry rice is more productive in yield per unit of labour than wet rice unless the plough be used. This conclusion, he maintained, is confirmed by the preference both among the Kachin of Upper Burma and the Dusun of Borneo for the cultivation of dry rather than wet rice where both methods were available. He suggested that the Angami terracing is due to military considerations rather than economic. With the plough, of course, the area cultivated by a normal household can be so much increased that there is a much greater economic surplus.

Prof. Christoph von Fürer-Haimendorf discussed the two preceding papers in the light of his experience on the north bank of the Brahmaputra in Assam, where the Apa Tani tribe, using hoes and not ploughs, support a population of 1,000 to the square mile on irrigated rice, of which they have a considerable surplus to trade for cattle and cloth to the neighbouring Daflas, who live in comparative poverty on the cultivation of dry rice, also by the use of the hoe, and have repeatedly to shift their villages as land becomes exhausted. This supported Prof. Hutton's view that irrigated rice is economically more profitable than dry. The Apa Tani system of wet cultivation preserves all the soil fertility and yields a perfectly balanced agricultural economy. The Apa Tani are a peace-loving people whereas it is the Daflas who have a bias towards war.

In the discussion that followed, it became pretty clear first that there was general agreement that, *provided* a long enough cycle of rest can be depended on, dry cultivation of the hillsides, which may b the only possible form of cultivation, need not in th long run be destructive of the soil fertility, or at an rate is not so wasteful or deleterious as administrativ and forest officers are inclined to assert; an secondly, that the question of the economic return of irrigated as compared to dry rice, per unit o labour expended, depends very largely on the rainfall and on the presence of a perennial water supply a point which largely accounts for the different view put forward by Prof. Hutton, from his experience o the Assam hills, and by Dr. Leach, whose experienc is of the drier climate of Upper Burma.

It was perhaps a pity that the discussion o primitive techniques was so largely limited to agriculture; but the importance of the subject was no left in any doubt.

NEWS and VIEWS

Prof. G. R. Goldsbrough, C.B.E., F.R.S.

PROF. G. R. GOLDSBROUGH'S retirement from the chair of mathematics at King's College, Newcastle-upon-Tyne, breaks a long and distinguished association with the College. He is an old student of the College, who returned to it in 1919 as lecturer in applied mathematics; in 1928 he was promoted to a professorship, and he has been head of the Department of Mathematics for the last three years. His research work has been mainly on two lines: in hydrodynamics he has made important contributions to the dynamical theory of the tides, and in astronomy he has elucidated the classical problem of the divisions in Saturn's ring. He was elected to the Royal Society in 1929. His interest in astronomy and geodynamics has been of special value in connexion with the work of the University Observatory at Durham. In addition to teaching and research, Prof. Goldsbrough has taken a leading and influential part in administrative and other activities in th University, and his sound judgment and advice hav been greatly appreciated. He was sub-rector of th College for the period 1942–47; and among man other duties he undertook the arduous task o chairmanship of the Joint Recruiting Board. H was awarded the C.B.E. in 1948. His colleagues an old students will wish him in his retirement man pleasant years of fruitful activity. He has bee succeeded at King's College by Profs. A. E. Gree and W. W. Rogosinski (see *Nature*, September 1 p. 445).

Biological Chemistry at Aberdeen :
Dr. W. O. Kermack, F.R.

DR. W. O. KERMACK, for many years in charge o the Chemical Laboratories of the Royal College o Physicians, Edinburgh, has been appointed to th recently established chair of biological chemistry the University of Aberdeen. This appointment will be received with a great deal of interest by all in the biochemical field, and with an element of surprise perhaps by some, for the appointment is probably unique in scientific circles in that Dr. Kermack is blind. To proceed to such an appointment in a laboratory subject has something in it of an act of faith, based not alone on the high scientific attainments but also on the rich mental endowments and sterling qualities of the new professor.

Dr. Kermack is an honours graduate in chemistry of the University of Aberdeen, where he received his B.Sc. degree in 1918. It was while a postgraduate research worker at Edinburgh that, in the course of an experiment, he met with the tragic accident which deprived him of all vision. To a lesser spirit such a catastrophe might well have spelt defeat; to Kermack it was but a challenge to re-orient his life to the steady continuance of his scientific work. That success has attended his efforts to a remarkable degree is seen in his activities in the spheres of mathematics, chemistry and music. His early research work was carried out in Oxford under the supervision first of Prof. W. H. Perkin and latterly of Sir Robert Robinson; his later work in colloid chemistry, on certain reactions of serum and cerebrospinal fluid, led on to the synthesis of compounds of possible antimalarial activity. This work has resulted in the synthesis of pyridoacridine and of *p*-phenanthroline derivatives, which have considerable chemotherapeutic activity on avian malaria. Dr. Kermack is joint author with Dr. P. Eggleton of "The Stuff We're Made Of" (1938); he is a D.Sc. of Aberdeen, was awarded the Freeland–Barbour Prize of the Royal College of Physicians, Edinburgh, the Macdougall–Brisbane Prize of the Royal Society of Edinburgh (1929), received the honorary degree of LL.D. of the University of St. Andrews in 1937 and was elected a fellow of the Royal Society in 1944.

Genetics at the John Innes Horticultural Institution

Dr. D. Lewis

Dr. D. Lewis is succeeding Dr. Mather, recently appointed to the chair of genetics at Birmingham, as head of the Genetics Department at the John Innes Horticultural Institution. Dr. Lewis was appointed from Reading in 1935 to work in the Pomology Department at the Institution. He has collaborated with Mr. M. B. Crane in the breeding of pears, raspberries and other fruits. For the last ten years, however, he has concentrated on the study of the incompatibility reaction in plants, using especially the Californian *Oenothera organensis*. He began with simple tests on the temperature relations. Later he introduced polyploidy and mutations, both spontaneous and induced, into his experiments. He has been able to split the incompatibility gene in *Oenothera*, with results of great physiological interest. He has also been able to calculate its natural mutation-rate in the sweet cherry, and at the same time use the mutations in producing self-fertile types in a hitherto self-incompatible species—a breeding device of great practical interest. Dr. Lewis' versatile experimental gifts should find suitable scope in his new post.

Women as a Labour Force in Britain

In Broadsheet No. 285, "Employment of Women", *Planning* (P.E.P.) examines some of the implications of the task of maintaining, and if possible increasing, the female labour of Britain at a time when the number of women of working age is declining. The difficulty is enhanced by the even greater decline in the number of women under forty-five years of age, from whom the bulk of the female labour force is drawn. The broadsheet points out that it is very important that employers should not be unprepared for the probable fall in the number of women in employment during the next fifteen years. The Ministry of Labour should forecast the probable trend in the number of women available for work in the various industries and regions, and should make the findings widely known. It must then be considered whether rising productivity will make good the loss of women workers, and if not, what adjustments should be made; in particular, whether to try to maintain the proportion of women in certain industries and occupations, or whether to allow the proportion to fall in all. Two conclusions stand out: first, that any substantial increase in the number of women in employment must come from married women; and, secondly, that if the female labour force is not to fall greatly, there must be a big rise in the number of middle-aged and elderly women in employment. By far the most hopeful means is to extend the opportunities for part-time workers. This is a desirable solution from the women's point of view; but from the employers' aspect entails careful organisation, additional supervision, and flexibility. In compensation there is evidence that part-time workers give good service, that their output is often higher than that of full-time workers, and that absenteeism and labour turn-over do not compare unfavourably. The importance of improving working conditions and providing more nurseries is stressed, and also of employing women who are in jobs to the best advantage. Those who aspire to a skilled, professional or executive job should have the opportunity, and the size, composition and distribution of the female labour force must not be left to chance.

French Abstracts

The *Bulletin Analytique*, published by the Centre National de la Recherche Scientifique, Paris, is an abstracting journal which appears monthly in two parts, Part 1 covering scientific and technical papers in the mathematical and physical sciences and their applications, Part 2 the biological sciences. The *Bulletin*, which started on a modest scale in 1940 with an average of 10,000 abstracts per part, now averages 35,000–40,000 abstracts per part. The abstracts summarize briefly papers in scientific and technical periodicals received in Paris from all over the world and cover the majority of the more important journals in the world scientific press. The scope of the *Bulletin* is constantly being enlarged to include a wider selection of periodicals. It thus provides a valuable reference book both for the laboratory and for the individual research worker who wishes to keep in touch with advances in subjects bordering on his own. A microfilm is made of each article as it is abstracted, and negative microfilm copies or prints from microfilm can be purchased from the editors. The subscription rates of the *Bulletin Analytique* for Great Britain are 4,000 fr. (£5) per annum for each part. The *Bulletin* is also issued in sections covering specific subjects. Subscriptions can be paid directly to the editors: Centre National de la Recherche Scientifique, 18 rue Pierre-Curie, Paris 5ème. (Compte-chèque-postal 2500–42, Paris), or through Messrs. H. K. Lewis and Co., Ltd., 136 Gower Street, London, W.C.1.

University of the Witwatersrand: Nuclear Physics Exhibition

THE chair of physics at the University of the Witwatersrand, Johannesburg, became vacant last year upon the retirement of Prof. H. H. Paine. The newly appointed head of the Department of Physics, Prof. G. T. R. Evans, delivered his inaugural lecture in the Great Hall of the University on September 23, taking as his subject "Radium: 1898–1948". Prof. Evans took the opportunity of paying a tribute to the memory of Madame Marie Curie and her husband. The vice-chancellor, Principal H. R. Raikes, who presided, expressed the appreciation of the University at the presence of M. Lancial, the Minister Plenipotentiary of the French Republic in South Africa. In connexion with the inaugural lecture there was held a two-day Exhibition in the Department of Physics under the direction of Prof. G. T. R. Evans. The film, "Marie Curie", was shown in the Great Hall; shorter films, "The Nuclear Structure of the Atom" and "Atomic Energy", were shown in the lecture theatre of the Department. The exhibition of nuclear phenomena, apparatus and films was open daily from 2.30 p.m. and attracted several thousand people. The exhibits included items of historic interest contributed by Madame Irene Joliot-Curie. Prof. A. M. Tyndall, of the University of Bristol, exhibited a collection of photomicrographs of nuclear tracks in photographic emulsions. The National Physical Laboratory of Pretoria demonstrated artificial radioactivity in biology. Other exhibits appreciated by the lay public were a working model of a cyclotron, a Wilson cloud chamber, Geiger counters and scalars, the medical use of radium and South African fluorescent minerals. This is the third exhibition organised by the Department of Physics since 1945; the crowds which gathered round the demonstrators until long after the hour for closing constituted convincing evidence of the appreciation of the Department's efforts to meet the layman's desire for a better understanding of modern physics.

Medical Research Council: New Members

BY an Order of the Committee of Privy Council for Medical Research, Lord Addison and Sir George Schuster have been appointed members of the Medical Research Council. With the approval of the Committee of Privy Council, the Medical Research Council has appointed Lord Addison to be its chairman in succession to Lord Balfour of Burleigh, and Sir George Schuster to be treasurer in succession to Sir William Goodenough. By the same Order, made in this respect after consultation with the Medical Research Council and with the president of the Royal Society, the following have also been appointed members of the Council: Sir Frederic Bartlett, professor of experimental psychology in the University of Cambridge; Sir Howard Florey, professor of pathology in the University of Oxford; and Prof. Geoffrey Jefferson, professor of neurosurgery in the University of Manchester.

Permanent International Association of Navigation Congresses

THERE has recently been formed, with the approval of the Ministry of Transport, a British National Committee in connexion with the Permanent International Association of Navigation Congresses. The main objects of the Committee are to foster interest in the Association, to promote papers for presentation at the congresses (in particular for the next congress to be held in Lisbon in September 1949) and generally to act as the co-ordinator of British interests in this connexion. The membership of the Committee is as follows: Sir William Halcrow (chairman), Mr. M. G. J. McHaffie, Mr. W. P. Shepherd-Barron, Mr. R. D. Gwyther, Mr. A. L. Harvey, Mr. C. A. Wilson, Mr. L. Cleaver, Sir Gilmour Jenkins, Mr. L. Leighton, Sir Cyril Kirkpatrick, Sir Arthur Whitaker and Mr. Maurice Nachshen. The Council of the Institution of Civil Engineers will administer and provide secretarial facilities to the National Committee. The Committee, at the request of the Secretary-General of the Association, has agreed to distribute in Great Britain bulletins, etc., received in bulk from Brussels, and also to receive on behalf of the Association subscriptions from members resident in Britain for onward transmission in a bulk sum or sums. Correspondence should be addressed to the Secretary, British National Committee, Permanent International Association of Navigation Congresses, at the Institution of Civil Engineers, Great George Street, London, S.W.1.

Royal Aeronautical Society

THE Royal Aeronautical Society has decided to form Divisions of the Society within the British Commonwealth, and steps are being taken to establish such Divisions in Australia and also in New Zealand by January 1, 1949. These Divisions (and those in other Dominions as formed) will have power to form branches of the Royal Aeronautical Society in their own countries, similar to those formed by the Society in Great Britain. Members of the Division will all be full registered members of the Society, and the Division will have the power to act in most respects exactly as the parent body in London. The only important exception is the actual election of members as associate fellows, so that a consistent standard will be set throughout the world; all such technical members will be elected by the Royal Aeronautical Society in London. But the Divisions will follow their own activities in their own countries in the ways which best suit that country and local conditions, and they will not be tied down in any way by rules or regulations which apply to Great Britain or the other Divisions.

Society for General Microbiology

AT a general meeting of the Society held at St. Andrews in September, the following were elected honorary members of the Society: Prof. O. T. Avery, Prof. Jules Bordet, Sir Alexander Fleming, Prof. A. J. Kluyver and Sir Charles Martin. In addition, a paper-reading session was held over two days, and thirteen demonstrations were given.

The officers and committee of the Society for 1948–49 are as follows: *President*, Dr. Marjory Stephenson; *Hon. Treasurer*, Mr. H. J. Bunker; *Joint Hon. Secretaries*, Dr. W. E. van Heyningen and Dr. J. G. Davis. The *Journal* of the Society is issued at about four-monthly intervals, and is edited by Dr. B. C. J. G. Knight and Dr. A. A. Miles, assisted by Dr. G. C. Ainsworth, Prof. W. B. Brierley, Dr. T. Gibson, Dr. A. T. R. Mattick, Dr. K. M. Smith, Dr. A. W. Stableforth and Dr. D. D. Woods.

Fourth Empire Mining and Metallurgical Congress

THE Fourth Empire Mining and Metallurgica Congress convened by the Empire Council of Mining and Metallurgical Institutions will be held in Great

Britain in July 1949, under the presidency of Sir Henry Tizard. The chief object of the Congress is to afford an opportunity for scientific men, engineers and others concerned with the mining and metallurgical industries to meet and discuss technical progress and problems, including the development of the mineral resources of the Commonwealth. The programme will be divided into three parts: July 9–12, inaugural meeting, official functions, exhibitions, visits, etc., in London; July 13–17, technical sessions in Oxford; July 18–23, excursions based for the most part on universities in Great Britain. Further information can be obtained from the General Secretaries, Fourth Empire Mining and Metallurgical Congress, 436 Salisbury House, Finsbury Circus, London, E.C.2.

Colonial Medical Research Fellowships

The Secretary of State for the Colonies has instituted a limited number of research studentships for graduates in medicine and cognate sciences, who desire by this means to prepare themselves for research work in tropical medicine and related subjects. They will be awarded on the advice of the Colonial Medical Research Committee, and will be tenable for two years at any university or other appropriate institution as approved by the Committee. The maximum rates of allowance payable are £300 per annum at the Universities of Oxford, Cambridge and London, and £260 per annum at other universities in the United Kingdom. Candidates must be British subjects and graduates of British universities. Application should be made, through the head of the candidate's Department, to the Secretary, Colonial Medical Research Committee, c/o Research Department, Colonial Office, Sanctuary Buildings, Gt. Smith Street, London, S.W.1, and should include, in addition to details of the candidate's academic record, some indication of the subject preferred.

A General Solution for the Force Constants of Polyatomic Molecules

Mr. P. Torkington writes with reference to the communication under the above title in *Nature* of September 4, p. 370: "It was stated that in the proposed solution the normal co-ordinate for ν_i involved only the co-ordinates Δ_i to Δ_n. In fact, it involves only the co-ordinates Δ_1 to Δ_i. The linear transformation giving the (unnormalized) normal co-ordinates η_i is found to be

$$\eta_i = \sum_{j=1}^{i} ({}^{i}|A|_{ij})\ \Delta_j.$$

The quantities on the right-hand side of equations (7) and (8) are coefficients in the reverse transformation, giving here the components in the displacement for ν_k in terms of η_k. In (8), the coefficients for Δ_1 to Δ_{k-1} are zero; it is therefore the form of the vibration, not the normal co-ordinate, which involves Δ_k to Δ_n only. Where $(\nu_i - \nu_{i+1})$ is small, and Δ_i and Δ_{i+1} overlap, η_i would be expected to involve Δ_{i+1}; η_{i+1} involves Δ_i in any event."

Announcements

The Lords Commissioners of the Treasury have appointed Dr. A. E. Trueman to be chairman of the University Grants Committee in succession to Sir Walter Moberly, who retires on October 1, 1949. Dr. Trueman, who has had a distinguished career as a geologist and a university administrator, became deputy chairman of the Committee in 1946 (see *Nature*, August 31, 1946, p. 299).

Dr. Robert Cruickshank, since 1945 director of the Central Public Health Laboratory of the Public Health Laboratory Service, has been appointed to the chair of bacteriology tenable at St. Mary's Hospital Medical School, London, as from January 1, 1949.

Dr. R. A. M. Case, until recently a principal scientific officer in the Royal Naval Scientific Service at the Royal Naval Physiological Laboratory, has taken up appointment at the Chester Beatty Research Institute of the Royal Cancer Hospital as research fellow under a scheme inaugurated by the Association of British Chemical Manufacturers, for the field and experimental investigation of the industrial incidence of papilloma of the bladder.

Dr. T. T. Paterson, who has resigned his post as curator of the Museum of Archæology and Ethnology, Cambridge (see *Nature*, September 18, p. 445), is to devote his time to research in the social anthropology of Britain, with special reference to problems of social medicine and group phenomena in the industrial, rural and urban fields. The investigation is being financed by a grant from the Medical Research Council.

The Leon Gaster Memorial Premium of the Illuminating Engineering Society, given annually for the best contribution submitted to and published by the Society during the session, has this year been awarded to Mr. J. N. Bowtell and Mr. H. G. Jenkins for their paper entitled "High Voltage Fluorescent Tubes". In view of the high standard of papers eligible for the award this year, the Council has made a second award to Messrs. H. K. Cameron, E. H. Rayner, E. R. Thomas and G. T. Winch for their paper entitled "Photometry of Searchlights" which forms part of the "Symposium on Searchlights" recently published by the Illuminating Engineering Society.

The Tilden Lecture of the Chemical Society will be delivered by Prof. C. E. H. Bawn in the rooms of the Society on November 11 at 7 p.m. Prof. Bawn will speak on "The Structure and Reactivity of Free Radicals".

A course of eight lectures on practical psychical research, beginning on October 16, has been arranged by the Society for Psychical Research and will be given at its house, 31 Tavistock Square, London, W.C.1. The topics to be discussed include the investigation of cases, extra-sensory perception experiments, and psychological and statistical methods. Tickets of admission (one ticket covers the whole course) can be obtained free from the secretary of the Society.

Dr. B. P. Dudding, honorary lecturer in industrial statistics, University of Sheffield, will give a course of eight lectures at the Sir John Cass Technical Institute, London, E.C.3, on Monday evenings at 7 p.m., beginning on October 25, on "Statistical Methods in Industry". A further course of lectures, also on Mondays at 7 p.m., beginning January 24, will be given by Mr. K. A. Brownlee on "Design of Experiments". The fee for either course is £1. Application for enrolment forms should be made to the Principal of the Institute prior to the opening date of the courses.

Structure of Calciferol

For some time it has appeared very desirable to undertake, for a calciferol derivative, a detailed X-ray analysis similar to that achieved for cholesteryl iodide[1]. Such an analysis should settle once for all many doubtful points in sterol chemistry and, incidentally, resolve the conflict between the early crystallographic and chemical evidence on the structure of calciferol[2]. The X-ray analysis of cholesteryl iodide was possible owing to the presence of the heavy iodine atom in the molecule, which permitted the direct calculation of electron-density projections. In the case of calciferol, our chief difficulty has been in finding any crystalline heavy-atom derivative. Dr. and Mrs. Cornforth were finally successful in preparing for us crystals of calciferol-4-iodo-5-nitrobenzoate, and from these we have now obtained evidence, by X-ray analysis, on the molecular structure of calciferol.

The crystals of calciferol-4-iodo-5-nitrobenzoate, $C_{35}H_{46}NO_4I$, are deep yellow prisms. They are orthorhombic with four molecules in the unit cell of dimensions: $a = 31 \cdot 2$, $b = 6 \cdot 98$, $c = 15 \cdot 3$ A., and space group $P\,2_12_12_1$. Their investigation followed a somewhat similar course to that adopted in the case of cholesteryl iodide. The x and z parameters of the iodine atoms were first found from a calculated Patterson (F^2) projection based on the intensities of the ($h0l$) reflexions. The first electron density projection was then calculated, using reflexions the phases for which could be determined from the iodine atom contributions alone; this projection indicated the configuration of the molecules and their general arrangement in the crystal. Approximate x and z parameters were then assigned to the other atoms in the crystal from this first projection. These parameters were refined and, in some cases, entirely changed through the calculation of two further electron density projections, based on phases calculated for all the atoms in the molecule. The final projection obtained is shown in Fig. 1 *a*, and its interpretation in terms of atomic positions in Fig. 1 *b*.

We have not so far completed the measurements on other zones of the crystal, so that we have, at present, no evidence on the y parameters normal to this (010) projection. While it should be simple to determine the y parameters of the iodine atoms, a prolonged and difficult three-dimensional analysis will be required to derive the y parameters of the remaining atoms.

We have, however, been fortunate in the crystal found for X-ray analysis. The fact that b is so short, 6·98 A., has given us a projection normal to this axis in which atoms of neighbouring molecules do not overlap; as a result, we have a projection of the calciferol structure which provides surprisingly good evidence on almost every detail of the chemical and stereochemical nature of the molecule. There is, in the first place, no doubt that ring *B* of the sterol skeleton is broken and that structure I, deduced on chemical evidence[3] for calciferol, is correct. In our crystal, however, the molecule does not maintain the curled-up configuration suggested by I, but exists in an extended form which may be approximately represented by II.

The detailed stereochemical relations of the atoms within the molecule (Fig. 2) are naturally interdependent; they may conveniently be traced from the point of attachment of the iodonitrobenzoyl group. First, the direction of the C(3) — **O** bond is only consistent with that described by Ruzicka, Furter and Goldberg as *t* or '*trans*'[4] in the original sterol skeleton (that is, *cis* to the methyl group at C(10) and C(13) in the ergosterol skeleton before ring breaking). This configuration is the same as that found for C(3) — I in cholesteryl iodide (cf. Dimroth[5]). Ring *A* itself has the expected appearance of a puckered six-membered ring in the 'chair' or *Z* form seen on its side. The directions at which the bonds C(10) — C(19) and C(5) — C(6) project are consistent with these being double bonds;

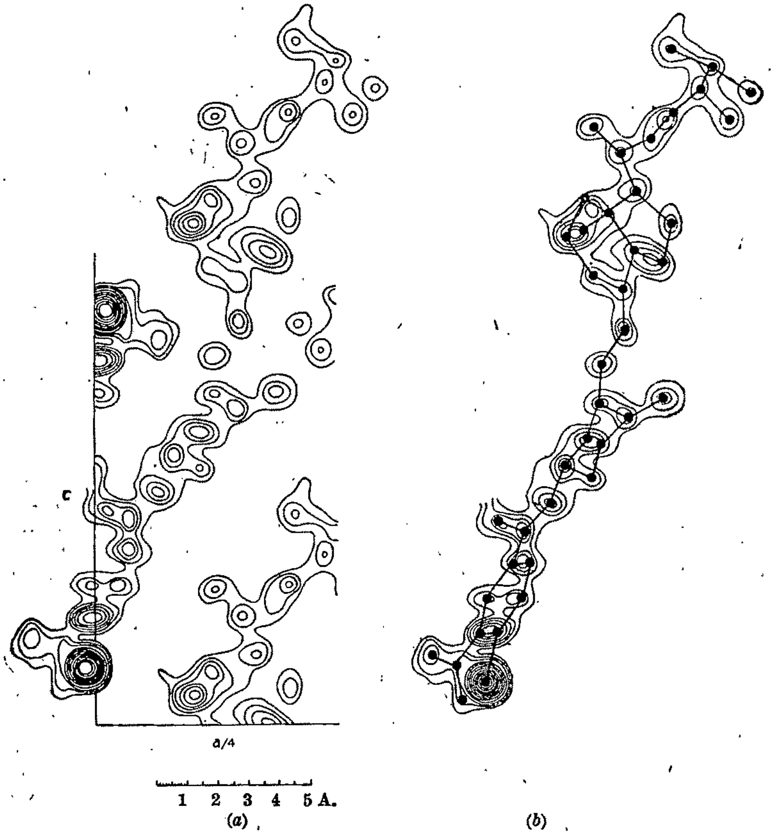

Fig. 1. (*a*) Electron density projection on (010) calculated for calciferol-4-iodo-5-nitrobenzoate. (*b*) The same with, superimposed, the positions derived for the atoms in the molecule. In both (*a*) and (*b*) only the electron density contours covering one of the four molecules which appear in this projection are shown in full

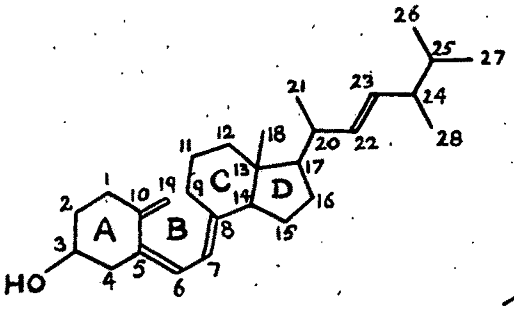
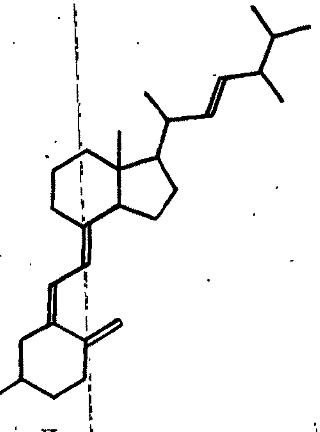


I



II

again, C(7) — C(8) is nearly parallel in projection with C(5) — C(6), as might be expected in a double-bonded system. Rings *C* and *D* are seen open in projection. Their appearance, particularly the parallel projection of bonds C(9) — C(8) and C(14) — C(15) combined with the position of C(16), seems only consistent with *trans* fusion of these two rings. The stereochemical relations at the centres C(13), C(17) and C(20) are as found in cholesteryl iodide, and the relation of these to the new asymmetric centre in calciferol at C(24) is shown. The main doubt that exists at present in the determination of these different points in configuration is in the relation of the two parts of the molecule separated by C(6) and C(7) (hence in the C(3) — O bond configuration). The relation described above depends on the probability that the bonds C(5) — C(6) and C(7) — C(8) are parallel in three dimensions. This probability is high, both on theoretical grounds and through the appearance of the projection. It will in any case be checked by the three-dimensional X-ray analysis of the structure.

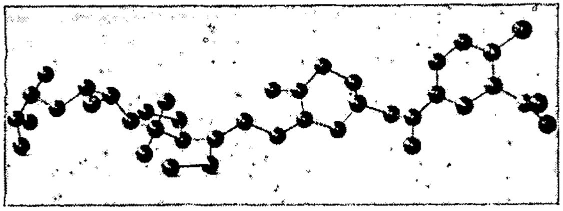


Fig. 2. Photograph of model showing the spatial arrangement of the atoms in calciferol-4-iodo-5-nitrobenzoate required by the electron density projection 1 *a*. This model shows one of the two permissible mirror-image forms of the molecule. The form chosen corresponds to the usual convention in the sterol series; compare, for example, Ruzicka *et al.* (ref. 5): it is not that given for cholesteryl iodide (see ref. 1). Hydrogen atoms are omitted

The way in which the molecules are fitted into the crystal structure as a whole is very intricate; it is one to which the unit-cell dimensions give no clue. It seems, therefore, quite possible that some similar unsuspected crystallographic complications exist in the calciferol crystals which were earlier examined, and that these led to a misinterpretation of the preliminary X-ray data. It is also conceivable that the calciferol molecule may adopt more bent or curled-up configurations in other crystals than that found here. Such differences could not affect the detailed chemical and stereochemical relations which are now clearly established.

In conclusion, we should like to thank those who helped us in our search for heavy-atom derivatives of calciferol, particularly Sir Robert Robinson, Dr. E. H. Carr, Dr. E. R. H. Jones, Dr. and Mrs. Cornforth and Dr. P. Meunier. The compound we used was first prepared in the Dyson Perrins Laboratory, Oxford, by Mrs. R. Cornforth from material given to us by Dr. E. H. Carr (British Drug Houses, Ltd.). It was later prepared in larger quantities at the National Institute for Medical Research, Hampstead, by Dr. J. W. Cornforth.

Surface Layers of Crystals

CERTAIN treatments of crystal surfaces result in the formation of surface layers with physical properties different from those of the undisturbed material[1–3]. It has hitherto been possible to measure the thickness of such a layer only by etching it away until the properties of the surface thereby revealed correspond to those of the crystal as a whole[4]. This method is unsatisfactory in that the effect of etching is uncertain: it does not take place uniformly, and it results in pitting, which may lead to erroneous estimates of layer thickness.

We have devised an X-ray method which yields the thickness of the surface layer without altering it physically. The method is described in detail elsewhere[5]: it involves measurement of the variation in the intensity of X-ray reflexion from a crystal, as the angle φ (Fig. 1), between the surface and the Bragg reflecting planes, is varied. The surface of the crystal is cut so that it is inclined at an angle ω to the Bragg planes, and by rotating the crystal about an axis normal to the planes the effective value of φ

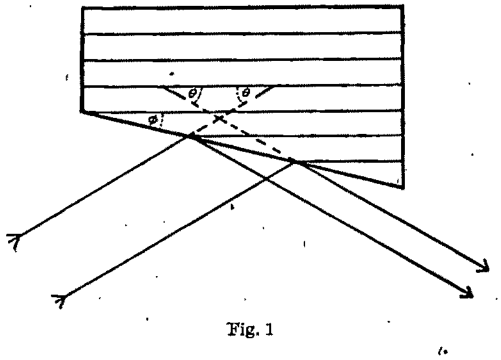

Fig. 1

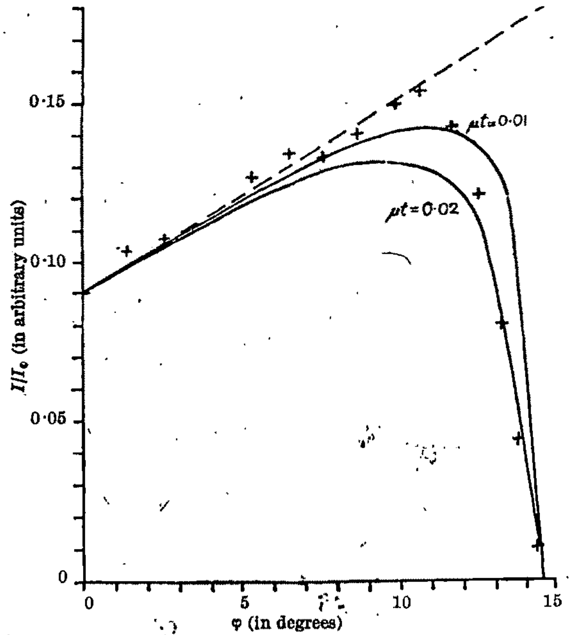

Fig. 2

may be made to vary from zero to ω, without disturbance of the surface.

For a crystal with no surface inhomogeneities an expression has been developed[6] for the ratio I/I_0 of reflected to incident beam intensity which is represented (suitably scaled) by the dotted line in Fig. 2. If, however, there are surface inhomogeneities such that the reflexion coefficient (K_θ') and absorption coefficient (μ') differ from the values ($K_\theta \mu$) appropriate to the main part of the crystal, then the variation of I/I_0 will follow a different law. A type of inhomogeneity particularly convenient for mathematical treatment is one where there is a surface layer of thickness t in which $K_\theta' = 0$ but $\mu' \neq 0$. The variation of I/I_0 with φ, for $\mu' t = 0{\cdot}01$ and $\mu' t = 0{\cdot}02$, is represented (suitably scaled) by the full lines in Fig. 2.

Other assumptions may be made about the variation of K_θ' with depth (for example, a linear increase up to the full value K_θ); but provided it be taken as an increasing function and μ' be taken as constant throughout the layer, curves very similar to those shown in Fig. 2 result. If the layer thickness be defined as the distance between the surface and the point where $K_\theta' = \frac{1}{2}K_\theta$, then it is found that the values of this thickness are almost independent of the particular assumptions made about the variation of K_θ'. Thus the method, while yielding a reasonable estimate of this half-value layer thickness, which is, of course, subject to some uncertainty about the value of μ', gives no information about the way in which K_θ' varies; except that, to explain the zero or very low value of I/I_0 at $\varphi = \theta$, it is in all cases necessary to assume K_θ' to be zero or very small at the surface.

We have applied this to determine the thickness of the surface layer on a crystal of calcite, ground and polished at an angle ω of 15° to a natural cleavage face. Electron diffraction photographs taken by reflexion from this surface showed intense background with slight central halation, such as one would expect from an amorphous material[2], justifying the assumption that K_θ' is zero at the surface. Applying the X-ray method described above, we obtained the experimental points shown in Fig. 2, which agree reasonably well with a theoretical curve, based on the above simplifying assumptions, and for a value $\mu' t \sim 1{\cdot}5 \times 10^{-2}$. For crystalline calcite $\mu = 205$ cm.$^{-1}$ for copper $K\alpha$ radiation, and it is reasonable to assume that it is not very different throughout the layer. Hence $t \sim 7{,}500$ A.

We are using this method to study ground and natural surfaces of single crystals and polycrystalline aggregates. It should be possible to measure by this means the thickness of any surface layer in which the value of K_θ' is different from that of the substrate material: one example is the layer on a polished metal surface, for which we have obtained interesting preliminary experimental observations; another is an electrodeposited layer of one metal on a base of a different metal.

We wish to express our thanks to Dr. V. E. Cosslett and Mr. G. R. Crowe for their aid in taking the electron diffraction photographs.

Ionization in Liquid and Solid Argon

Ionic mobilities in liquids are of the order of 10^{-3} cm.^{2}/volt/sec., and ion chambers filled with liquids are therefore generally useless in connexion with pulse amplifiers. Free electrons should have a much higher mobility; but their path before capture is extremely short in most liquids. We have been unable to detect them in carefully purified hexane. However, in condensed argon, charge carriers with a mobility greater than 40 cm.^{2}/volt/sec. have been found, and these are undoubtedly electrons.

The argon was purified by repeated passage over copper turnings at 400° C., and then condensed into the chamber by cooling, with liquid oxygen to produce the liquid, or with liquid nitrogen to produce the solid. The chamber had parallel, horizontal plates the distance apart of which could be varied between 1 and 5 mm.

The biggest pulses observed with liquid argon irradiated with gamma rays from radium C were, with fields of 10,000 volts per cm., about what was expected from complete electron collection (assuming an average energy loss by the Compton electrons of 25 eV. per ion pair formed). The pulses are distinctly smaller in fields of 2,500 volts per cm.

In solid argon much bigger pulses were found with fields of more than 13,000 volts/cm., indicating electron multiplication by a factor of more than 12. This phenomenon is, however, transient and disappears at a rate depending on the rate of charge collection as the cell polarizes. The polarization is not just due to the possible presence of a gas space between the solid and the top electrode, because it still occurs when the top portion of the cell is filled with liquid. The effect is similar to that reported in diamond and selenium[1].

If, after polarization had occurred, the chamber potential was removed, pulses continued with the same sign, in contrast to the reported behaviour[2] of silver chloride crystals, which show pulses of the opposite sign. This difference may be connected with the occurrence of secondary ionization in the argon in the fields used. If the cell contained a layer of solid argon below and liquid argon above, the predominant sign of the pulses after switching off the field always corresponded to an accumulation of positive space charge in the solid, no matter which had been the sign of the polarizing field.

An attempt was made to observe electron multiplication in the liquid by the use of a proportional counter made with a 15-micron wire in a cylinder of 5·2 mm. diameter; but only ordinary sized pulses were observed up to the maximum potential of 4,000 volts. In the solid, multiplication greater than ten-fold was found at potentials as low as 500 volts, but polarization was too rapid for accurate measurement.

Further information was obtained with a chamber in which the upper (collecting) electrode was screened by a fine wire grid. Pulses were observed with solid argon in part of the lower portion of the cell (the remainder containing the gas), but not when the solid was replaced by liquid. This indicates that in the fields used (greater than 500 volts/cm.), some electrons in the solid but not in the liquid have enough energy to escape into the gas phase.

Properties of ionization pulses in liquid and solid argon and other condensed media have recently been reported[3]. These experiments were done with alpha-particles and produced pulses about half the expected size. This is perhaps due to recombination, because of the denseness of the ionization tracks, and the effect may well be absent when ionization is due to fast electrons as in our experiments.

Sound Velocity and Temperature Change of Molecular Association

USING an acoustical interferometer (frequency of the quartz crystal, 539·6 kc./s.), we have measured the velocity of sound in various liquids (carbon tetrachloride, benzene, ethyl ether and carbon disulphide) between 80° C. and the melting point of these liquids (see Fig. 1). In order to check the degree of association of the liquids at low temperatures, we computed from our measurements the relative ssociation: $R = (v_m{}^{1/3}/d_m)/(v^{1/3}/d)$, using the empirical equation of Rao[1], which has also been applied by Weissler[2].

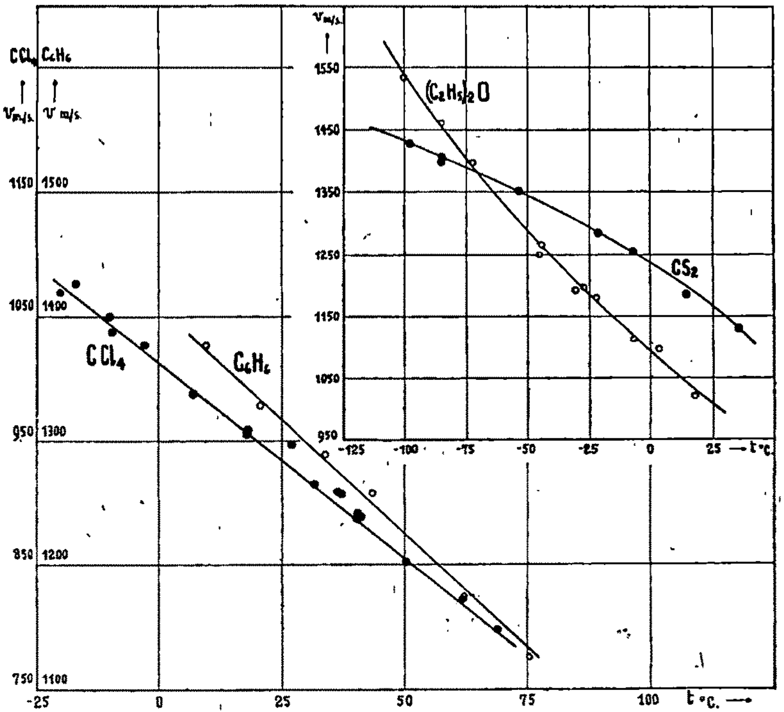

Fig. 1

v and d are the velocity of sound and density corresponding with the same temperature. In the case of no association, R is a constant.

This relative association (see Fig. 2) is taken as 1·000 at the respective melting points. The values for v_m are obtained by extrapolating our data down to the melting point. The values for the densities are taken from data published respectively by Isnard[3], Meyer[4], and by Richards, Speyers and Carver[5]. From Fig. 2 we see that an approximately straight line is obtained for carbon tetrachloride, while for the other liquids the lines are curved. The result for water obtained by Weissler[2] is also indicated.

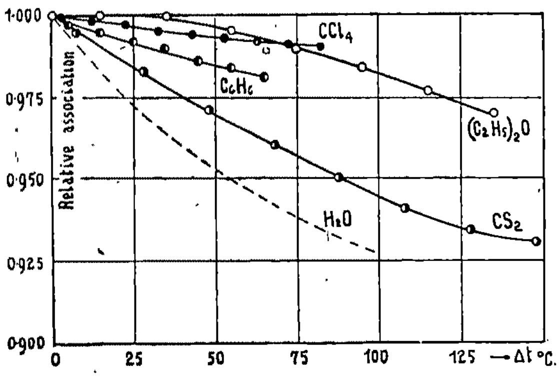

Fig. 2

In connexion with this problem of association, it is interesting to compute the relative association for helium I and II, using for this purpose the known experimental data for the velocity of sound obtained by Findley, Pitt, Grayson Smith and Wilhelm[6], and Pellam and Squire[7], and the densities of liquid helium under its saturated vapour pressure (Keesom and Keesom[8]).

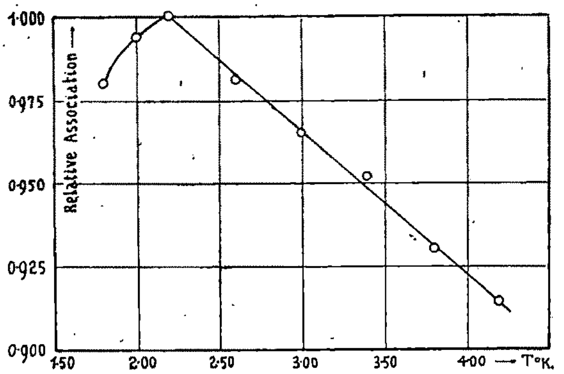

Fig. 3

The relative degree of association is taken as 1·000 at the λ-point. The results obtained are given in Fig. 3. We see that for helium I a straight line is found, whereas for helium II the line is curved. Further, the decrease of relative association is of the same order as for water[2] (see Fig. 2).

Magnetism of Celestial Bodies and Gravitation

BLACKETT's formula[1] involving a relation between mechanical and electromagnetic quantities seems to indicate a new kind of connexion between gravitation and electromagnetism. This appears more distinctly in Wilson's relation :

$$\sigma = \sqrt{K}\rho, \tag{1}$$

where the charge density σ is associated with the mass density ρ by the Newtonian gravitational constant K. There is no room in Newtonian theory for an explanation of (1). The situation is better in the relativistic theory of gravitation.

For an isolated and limited fluid surrounded by a static gravitational field, and at rest with respect to a co-ordinate system which is Galilean at infinity, the total energy is given by[2] :

$$E = \int (T_4^4 + t_4^4)\, dV = mc^2, \tag{2}$$

where T_4^4 is the temporal component of the momentum-energy density tensor of the fluid, t_4^4 the temporal component of the gravitational energy density, dV the element of proper volume and *m the proper mass of the fluid*, equal to the constant of Schwarzschild's external line element[3]. For a sphere it is approximately equal to[4]:

$$E = \int_{v} \rho c^2\, dV + \tfrac{1}{2} \int_{v_0} \rho\psi\, dV_0, \tag{3}$$

where ψ is the Newtonian potential and dV_0 the elementary Euclidean volume, the integral being extended to the domain occupied by the fluid. When the body is a perfect spherical fluid[5] we have :

$$-3 \int p\, dV_0 = \tfrac{1}{2} \int \rho\psi\, dV_0, \tag{4}$$

where p is the internal pressure. In Newtonian approximation, dV reduces to the Euclidean elementary volume dV_0 and (3) yields: $E = mc^2 - W$ ($W = -\frac{1}{2}\int \rho\psi\, dV_0$). Therefore (2) indicates that there is in relativity a supplementary energy W which is such that according to (2) $E = mc^2$. The same conclusion is valid if the field of force inside the body is given by Schwarzschild's line element for a spherical incompressible fluid. This can be easily checked by computation of (2), using Dingle's formulæ[6].

The existence of W is due to the fact that the first integral in (3) is extended over a non-Euclidean space, for which the total volume occupied by the fluid is greater than that obtained by using a Euclidean metric. In spite of the very small difference between these volumes, the supplementary energy obtained in this way is not negligible. In Schwarzschild's case, with a as the Euclidean radius of the sphere, we get[7] :

$$m'c^2 = \int \rho c^2\, dV = \rho \frac{4\pi}{3} a^3 \left[1 + \frac{3}{5}\frac{Km}{c^2 a} + \dots\right], \tag{5}$$

and thus we obtain the supplementary energy[8]:

$$W = m'c^2 - mc^2 = \frac{3}{5}\frac{Km^2}{a}. \tag{6}$$

The physical origin of this energy is unknown. Obviously, it cannot be attributed to the internal pressure or to the Newtonian action of the gravitational field. Let us assume that it is due to a partial separation of the charges contained in the atoms of the neutral fluid. To support this hypothesis we must notice that an atom which possesses spherical symmetry and no permanent electric moment in a Euclidean space has ellipsoidal symmetry and a small permanent electric moment in Schwarzschild's internal field, as will now be shown. Schwarzschild's internal spatial line element is :

$$dl^2 = dr^2 \Big/ \left(1 - \frac{2Kmr^2}{c^2a^2}\right) + r^2\,(d\theta^2 + \sin^2\theta\, d\varphi^2). \tag{7}$$

According to (7), the length measured in the direction perpendicular to the radius r is the same as in Euclidean geometry, while the length measured along this radius,

$$\int dR = \int \left(1 + \frac{Kmr^2}{c^2a^3}\right) dr, \tag{8}$$

is greater[9]. Therefore, a sphere is changed into an ellipsoid by penetrating into the fluid. This involves, owing to the structure of the atoms, a small polarization.

But we cannot directly use such a precise mechanism, because it is special to Schwarzschild's co-ordinate system. In an isotropic system, the Euclidean length is modified by the curvature of the space in the same manner whatever the orientation[10]. However, in spite of the indeterminacy of the co-ordinate system, since the electric charge is a relativistic invariant, the existence of such a charge in a special co-ordinate system ensures its existence in all others. We have only to admit that the relativistic expansion of the internal space induces a partial separation of the charges of the two signs composing the neutral fluid. Having assumed that the electrical energy which results from such a separation is equal to the supplementary energy (6), we now obtain (1).

According to (5) and (1) the total charge resulting from the separation is $e = \sqrt{K}\int\rho\, dV$. The fact that the non-Euclidean volume of the fluid exceeds the Euclidean volume of the Newtonian physics gives rise to an additional charge which is given by:

$$\varepsilon = \sqrt{K}\int\rho\,(dV - dV_0)$$

$$= \sqrt{K}\rho\,\frac{4\pi}{3}a^3\left(\frac{3}{5}\frac{Km}{c^2a}\right) = \left(\frac{\sqrt{K}\rho\, Km}{5c^2}\right)4\pi a^2. \qquad (9)$$

This can be regarded as a surface charge of density $\eta = \frac{K^{3/2}\rho m}{5c^2}$. For the earth, the computation gives $\eta = 1{\cdot}26 \times 10^{-4}$ e.s.u./cm.². The experimental facts indicate that the surface of the earth possesses a negative charge the average density of which is $-\,2{\cdot}7 \times 10^{-4}$.

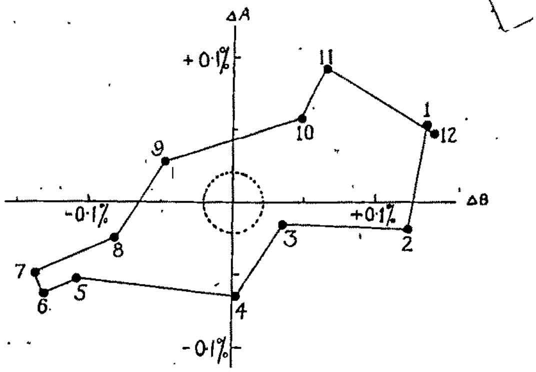
Sidereal Variations of Cosmic Rays

DUPERIER[1] has analysed the first harmonic of the apparent solar diurnal variation of cosmic rays at London, using a method due to Thompson[2]. He inds that the first harmonic for any month has three components, namely, (i) a mean solar vector M, i) a vector, A, altering the amplitude of M, and ii) a vector, P, controlling the change of phase of M. 'he P vector may arise from either (*a*) a sidereal iurnal variation, (*b*) an annual solar variation, or) a combination of these effects. This communication iscusses the interpretation to be placed on the P ector, by comparing Duperier's figures for London ith the results obtained at Canberra.

Analysis of the first harmonic of the apparent solar diurnal variation of cosmic rays

Vector	London (local mean time)		Canberra (local mean time)		Canberra (local apparent time)	
	Amplitude % ± p.e.	Time of maximum	Amplitude % ± p.e.	Time of maximum	Amplitude % ± p.e.	Time of maximum
M	0·41 ± 0·02	16·3h. (L.M.T.)	0·67 ± 0·02	15·0 ± 0·1h.	0·67 ± 0·02	15·0 ± 0·1h.
A	0·36 ± 0·02	June-	0·22 ± 0·02	Mar. 27 ± 12d.	0·20 ± 0·02	Apl. 7 ± 12d.
P(*a*) Sidereal ..	0·21 ± 0·02	21h. (L.S.T.)	0·05 ± 0·02	9·6 ± 0·7h. (L.S.T.)	—	—
(*b*) Solar	0·21 ± 0·02	March-	0·05 ± 0·02	Sep. 25 ± 12d.	0·03 ± 0·02	Nov. 12 ± 12d.

The Canberra results were obtained with an ionizaon vessel and were corrected for bursts, pressure ıd temperature[3]. A harmonic analysis was made of ıe apparent solar diurnal variation averaged for each month of the year over a period of five years. From these analyses a harmonic dial was constructed showing the month-to-month change of the first diurnal harmonics. Smoothed points in this dial progressed clockwise in a closed figure, as found also by Duperier. An ellipse was fitted to the unsmoothed points by harmonic analysis of the deviations from the mean solar vector, and this gave the vectors A and P for comparison with Duperier's data. The accompanying table shows that the P vector, interpreted as a sidereal effect, exhibits a phase difference of about twelve hours between the northern and southern station. It seems preferable, therefore, to regard the P vector as representing, in the main, merely an annual change in the phase of the true solar diurnal variation, making the diurnal maximum occur earliest in the spring at both places.



Annual changes in the deviations from the mean of the cosine (A) and sine (B) components of the first harmonic of the apparent solar diurnal variation of cosmic rays at Canberra, arranged according to local mean time. 1 = Jan.; 2 = Feb., etc. The central circle indicates the probable error of the monthly points (± 0·02 per cent)

If the P vector is regarded as being of solar origin, it is appropriate to reduce the results according to local apparent time rather than local mean time. Local apparent time values for A and P are slightly smaller for the former than for the latter. It seems that any sidereal variation of cosmic rays with a 24-hour period would be extremely small, for the P vector (local apparent time) of 0·03 per cent (equivalent to a maximum change of phase of about 10 min.) would have to take account of not only the sidereal process, but also of any change in the lag between the cosmic rays and the sun's position. It seems likely that no 24-hour sidereal variation has been detected in these measurements, and that, in terms of the theory advanced by Compton and Getting[4], an interstellar rather than an intergalactic origin should be assigned to cosmic rays.

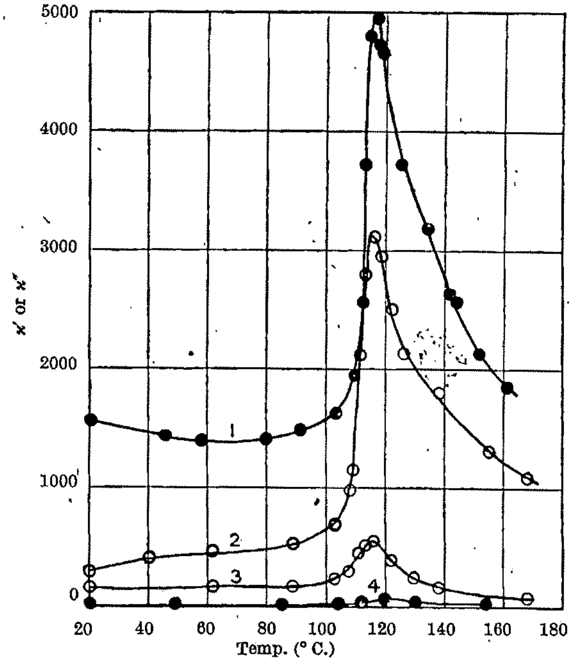
Dielectric Properties of Titanates at Ultra-high Frequencies

The complex permittivity ($\kappa' - j\kappa''$) of a series of titanates, magnesium, calcium, strontium and barium, has been measured at 21° C. and frequencies of 1·5 and 9,450 Mc./s., and of the barium titanate at 24,000 Mc./s. also. In addition, the behaviour of barium titanate at 1·5 and 9,450 Mc./s. has been studied over the temperature-range + 20° to + 170° C. The results of these measurements are recorded in the accompanying table and diagram. The electric field-strength applied to the test specimens was estimated as less than 1 volt/cm.



Dielectric properties of barium titanate at 1·5 Mc./sec. and 9,450 Mc./sec. Curves 1, κ' at 1·5 Mc./sec.; 2, κ' at 9,450 Mc./sec.; 3, κ'' at 9,450 Mc./sec.; 4, κ'' at 1·5 Mc./sec.

The loss tangent ($\tan \delta = \kappa''/\kappa'$) of the magnesium, calcium and strontium titanates at 9,450 Mc./s. was sufficiently small to permit the use of a technique, described in an earlier communication[1], which consists in measuring the variation with frequency of the energy transmitted through a slab located in, and filling, the cross-section of a wave-guide. The attenuation in barium titanate, however, proved to be so high that this method could not be used, and the complex permittivity was determined by measurement of the reflexion from and transmission through a slab, at fixed frequency. For the reflexion measurements it was sufficient to consider only the front face of the specimen, since internal reflexions were highly attenuated. In order to reduce the power standing-wave ratio in front of the face to measurable values, quarter-wave 'matching' slabs of lower permittivity materials were used. For example, with 'Tempa S', $\kappa' = 11\cdot3$, the power standing-wave ratio was reduced by 320 : 1 and with polystyrene, $\kappa' = 2\cdot56$, by 17 : 1. The attenuation in the material was obtained by measurement of the transmission through specimens with matching slabs at each side. From a combination of the results of the two measurements, values of κ' and κ'' can be calculated.

At 21° C.

Material	κ'			$\tan \delta = \kappa''/\kappa'$		
	1·5 Mc./s.	9,450 Mc./s.	24,000 Mc./s.	1·5 Mc./s.,	9,450 Mc./s.	24,000 Mc./s.
$MgTiO_3$	13·0	11·3	—	0·0012	<0·05	—
$CaTiO_3$	140	132	—	0·0007	<0·015	—
$SrTiO_3$	264	232	—	0·0009	<0·03	—
$BaTiO_3$	1,500	300	126	0·015	0·53	0·59

It will be seen from the table that the room-temperature permittivity values at 9,450 Mc./s. of the magnesium, calcium and strontium titanates are not appreciably different from the 1·5 Mc./s. figures, but that for barium titanate a substantial decrease has occurred at the higher frequency, and a still further decrease at 24,000 Mc./s. In keeping with these observations, while the loss tangent of the magnesium, calcium and strontium titanates does not exhibit a particularly marked increase with frequency, that of barium titanate has risen to a very high value at the two ultra-high frequencies. It has not yet been possible to extend the range of frequency measurement, but there can be no doubt of the existence of dispersion in barium titanate in this region of frequency, a fact which will be of considerable significance in the interpretation of its genera behaviour.

The variable temperature measurements at 9,450 Mc./s. on barium titanate show that although the permittivity is lower throughout than at 1·5 Mc./s., the rapid rise to a peak value occurs at substantially the same temperature in the two cases.

A full report of the work will appear elsewhere; but I wish to acknowledge here the help afforded by the United Insulator Co. and the Mullard Radio Valv Co. in supplying the ceramic specimens, and to thank the Department of Scientific and Industrial Research for financial support of the work.

New Photoconductive Cells

So far there are few substances known to posses photoconducting properties with a quantum yiel appreciably greater than unity. The chief ones ar selenium, oxidized thallous sulphide, and the sulphid selenide and telluride of lead.

Two questions arise : (1) Are the above-mentione substances the only possible ones, and, if so, wh is the reason for that ? (2) What is the role of th oxygen in sensitizing at least thallium and lea sulphides, lead selenide and lead telluride ?

Experiments with various types of semi-conducto suggested to me that the particular action of tl oxygen can be best accounted for if it is assume that the oxygen is adsorbed on the semi-conduct particles during evaporation and after the depos has been formed, and not, or only partly, as secondary process, taken up by the lattice. It known that adsorption of gases on finely divid metals is much increased if an electric discharge passed through the vessel containing the adsorben

If the above-mentioned view is correct, metho which produce a layer of material by a process which an electric discharge is active should yield photoconductive sensitive deposits. Several methods were tried and it was possible to produce highly sensitive cells not only with materials already known to possess photoconductivity, but also with a great number of new substances.

The following methods were used: (1) cathode sputtering with the substance as the cathode; (2) electric discharge between aluminium electrodes and evaporation of the substance from a heater spiral; (3) low-voltage arc with the substance as the anode; (4) a molecular beam of the substance crossing a beam of gas ions before condensing on the carrier. The gas used was oxygen or air and the pressure varied between wide limits depending on the substance ($0\cdot5$–10^{-4} mm. mercury).

Using one or the other of the above methods[2], it was possible to produce photoconductive cells of a series of substances which can be divided into two groups. The first group is characterized by the following properties: if the carrier is kept at room temperature or lower during the production, the film has a high resistance, a high negative temperature coefficient of resistance β and has its optimum sensitivity in the near infra-red. Heating the film in air or oxygen afterwards reduces the sensitivity, the resistance and β, and in some instances, for example, platinum, a film with normal metallic properties results. Some substances belonging to this group are platinum, nickel, antimony and germanium.

Substances of the second group have properties similar to those of the first group before heating. Heat treatment of the film in air or oxygen at a low temperature and for very short time reduces the resistance, β, and the sensitivity appreciably; but a prolonged heat treatment at a higher temperature increases the three properties again and, if the conditions are properly chosen, a cell of very high sensitivity may result. The substances investigated up to now and belonging to this group are: the sulphides, selenides and tellurides of lead, tin, indium, thallium, cadmium, bismuth and antimony, and some intermetallic compounds, for example, CdSb. Most of the tellurides show high sensitivity only at − 78° C. or at liquid-air temperature. Some of the sulphides are very sensitive even at room temperature.

Although the general behaviour of all the deposits produced up to now is similar, there are very wide variations in the absolute values of the resistance, β, the sensitivity, and the spectral distribution of sensitivity for even the same substance, depending on the conditions of production and on the following heat treatment. The properties of a layer of indium telluride are given as an example to indicate this general behaviour. Evaporation of the substance was carried out according to method 3 in air ($p = 0\cdot05$ mm. mercury) and the deposit formed on a glass strip, fixed at 40 mm. distance from the source and cooled by running tap water. The deposit thus formed after several seconds was just transparent and brown in transmission. The resistance of a sensitive area of 4 mm. length and 1 mm. width was of the order of 250 megohms at room temperature. The sensitivity for visible light and the near infra-red was very low and β was negative. Heating the layer in air to approximately 100° C. for 2 min. reduced the resistance to 0·3 megohms. Further heating in air at 160° C. for 15 min. produced a resistance of 2·4 megohms at room temperature and the sensitivity increased manifold. At liquid-air temperature the resistance was 120 megohms, and the cell was superior in performance to a Schwarz–Hilger vacuum thermopile as far as 2·2 μ.

It is common to all the cells, with the exception of thallium sulphide and of selenide, that they are stable in air. It is easily possible to produce cells of any size and shape and, as a great number of cells can be produced at the same time, the uniformity and reproducibility are very good. The colour in transmission of most sensitive cells is brown to red-brown, indicating that this property is not so much dependent on the special substance as on a specific arrangement and size of the deposited particles, which must be similar in all cases.

The primary condition which must be fulfilled to produce a sensitive layer is that β should be negative; this depends on the gas pressure, the length of the path the evaporated particle travels before it reaches the carrier and the electrical conditions of the discharge.

If dissociation of the substance is too high, the metallic part of the compound is evaporated first by one of the above methods and this metal deposit afterwards transformed into the compound by heating it in an evacuated tube and passing a stream of the other constituent over it. With this method it was possible to produce, for example, photoconductive sensitive cells of silver sulphide, selenide and telluride.

The theoretical implication of these discoveries and a full description of the experimental results will be given elsewhere.

Hydrogen Peroxide and the Indirect Effect of Ionizing Radiations

In a recent paper, Allsopp[1] has suggested that the old 'poison' hypothesis for the action of ionizing radiation on living cells might be revived in terms of the 'hydroxyl radical' as the specific poison. Results of experiments on bacteriophage *S*13, undertaken at the instigation and with the support of the late Dr. D. E. Lea, suggest that for certain *in vitro* experiments, at least, on the indirect effects of ionizing radiation, a poison hypothesis in quite direct terms will explain the results satisfactorily, the specific poison being hydrogen peroxide. As has been pointed out[2], the fact that hydrogen peroxide is formed in irradiated water itself requires explanation in terms of a theory such as that of Weiss[3]; but it has become evident that all the observed facts on 'indirect' action of radiation on this particular phage are fitted by the explanation that when the phage is in dilute solution the hydrogen peroxide formed by ionizing radiations will inactivate it. The following results support this explanation.

(1) Tests with titanium sulphate show that the quantity of hydrogen peroxide produced when the phage is in dilute solution is of the expected order of magnitude[4].

(2) Survival curves for the phage irradiated in dilute solution were sigmoid; that is to say, the rate of inactivation increased with increasing dose

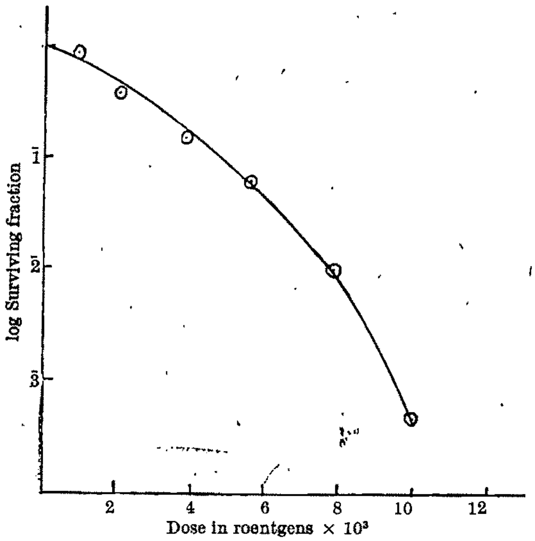

Fig. 1. Inactivation of phage *S*13 suspended in clean phosphate buffer. Composite curve, three experiments

(Fig. 1). When the buffer in which the phage was suspended had received a previous irradiation of some hundred thousand roentgens, however, the survival curve was exponential (Fig. 2), indicating that such a curve is obtained after the quantity of hydrogen peroxide in the solution has reached an equilibrium, or at any rate a minimum value.

(3) Disinfection experiments using a quantity of hydrogen peroxide of the same order as that formed in the suspension in the irradiation experiments yielded the usual form of exponential disinfection curve.

(4) A temperature effect was discovered in the irradiation experiments, the rate of inactivation being lower at lower temperatures. This is not easily explained on the 'active radical' hypothesis, but fits in with the well-known temperature effect in any disinfection process.

(5) The increase in activation dose with increasing concentration was found to be analogous with that found in other virus experiments[5,6]. The addition of protein to a dilute solution was found to protect the phage in irradiation experiments. In hydrogen peroxide disinfection experiments, similar results are obtained; for example, the addition of 5 per cent peptone to a dilute phage solution in the irradiation experiments fully protected the phage, so that the inactivation dose equalled that required for a dry phage suspension. The same percentage of peptone protected the phage fully against the hydrogen peroxide in concentrations which inactivated the phage rapidly when suspended in buffer free from organic material. Here again is the usual action of organic material in protecting organisms against disinfection by an oxidizing agent.

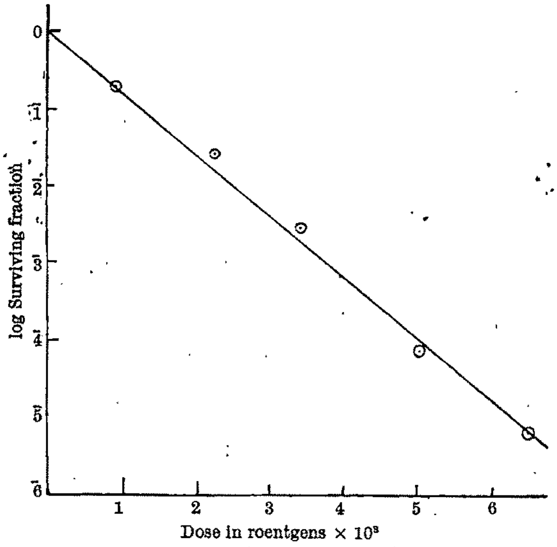

Fig. 2. Inactivation of phage *S*13 suspended in pre-irradiated buffer. Composite curve, three experiments

In experiments on 'indirect effect' of ionizing radiations, the ratio of ionic yield for direct action only to ionic yield in dilute solution is of importance for gaining an insight into the 'active radical' mechanism. It is clear that where the experimental material is in any way sensitive to hydrogen peroxide, this ratio may, in fact, be yielding information only on the production of hydrogen peroxide.

This work was begun at the Strangeways Research Laboratory, Cambridge, and continued in the Medical Research Council Radiotherapeutic Research Unit, Hammersmith Hospital, London, and at the Onderstepoort Laboratories, Transvaal. I have to acknowledge with gratitude the kind hospitality of all three institutions and the interest and assistance of Dr. F. G. Spear of the Strangeways Research Laboratory. The work was started as part of the experimental programme of the late Dr. D. E. Lea, and was continued with the support and constant advice of Dr. L. H. Gray.

The results will be more fully published elsewhere.

Air-Cored Synchrotron

THE air-cored synchrotron[1,2] appears to have a number of very attractive features, especially if only infrequent pulse operation is required, say, for cloud-chamber experiments, for in such a case the condensers provided to store the magnetic field energy can store perhaps twice as much as when used on alternating current. If, in addition, it proves possible to hold the electrons to a very narrow region so that the guide field is used efficiently, then energies in the 500-MeV. region seem attainable with condenser banks already available in physical laboratories. The upper limit of energy is then set by the deformation of the conductors under the mechanical forces, so that the total impulse becomes the relevant quantity. Thus it is important to use rapidly rising magnetic fields, and a condenser-coil system either nearly critically damped or incorporating a rectifier, so that a slowly damped train of oscillations do not add unnecessarily to the impulse handed on to the coil system. We are pursuing experiments which indicate that impulsive forces greatly in excess of the static ultimate strengths of the coil materials can be withstood.

Particle accelerators of the synchrotron (and cyclotron) type are characterized by the fact that of the three fundamental quantities *H* (magnetic field), *r* (orbit radius) and *f* (frequency of accelerating electric field), two in general must vary during the acceleration. The exceptions are for the extreme cases of non-relativistic particles (cyclotron acceleration, *r* only varies) and extreme relativistic particles (synchrotron acceleration, *H* only varies).

The acceleration of electrons from relatively low energies to extreme relativistic energies by conventional synchrotron techniques may be accomplished in two ways: either the frequency of the electric field may be kept constant and the equilibrium radius allowed to vary, or the radius may be kept constant and frequency modulation employed. The first of these is excluded when we wish to keep the guide-field energy low, and the second does not seem to have been adopted, doubtless due to the technical difficulties of frequency modulating. These difficulties are made worse for air-cored machines, where for the reasons given the modulation would have to take place rapidly.

Betatron acceleration for bringing the electrons up to relativistic energies as in conventional iron-cored synchrotrons is also possible, but unattractive, since it is extravagant in condensers and furthermore the central betatron flux must be steered away from the guide-field region, a difficult problem in coil design.

The object of this communication is to propose a method of bringing the electrons up to the relativistic region, which while generally applicable may be specially attractive for an air-cored machine, since the radial drift of the electrons is limited, the exciting oscillator frequency is constant, and the effect is obtained by blanking off the oscillator at appropriate moments.

The principle of this method is to make the frequency of the accelerating radio-frequency field an integral multiple, ν, of the frequency of revolution of the electrons at injection, which takes place at the inside of the doughnut. If the injection voltage is sufficiently high, a synchronous beam will be obtained, individual electrons oscillating about an equilibrium orbit which expands as the magnetic guide-field is increased. This expansion is allowed to proceed until the electron energy is such that if it were at the inside of the doughnut its frequency of rotation would be $1/(\nu - 1)$ times that of the applied electric field, which is then suppressed until the equilibrium orbit shrinks to the inside. The radio-frequency field is reapplied, and this sequence is repeated until the electron energy reaches the extreme relativistic region, when the machine becomes identical with the conventional synchrotron, except that the applied radio-frequency will still be some multiple (less than ν) of the frequency of electron rotation. The greater the number of expansions and contractions (that is, the larger ν), the smaller the range of variation of the orbital radius during acceleration and thus the greater the machine efficiency from the point of view of energy storage.

To obtain adequate injection efficiency, the radio-frequency voltage must be sufficient to give a fairly large initial amplitude (Δr) of the radial oscillation corresponding to the phase oscillations of the electrons, so that one fills an annulus of width $2\ \Delta r$. Subject to this condition, one finds in practice that the range of phase stability extends over a large fraction of the radio-frequency cycle.

The theory of Bohm and Foldy[3] enables us to determine the fraction of electrons accepted at each expansion, assuming the radio-frequency amplitude builds up instantaneously, and for the machine detailed below this would average about 70 per cent, that is, an overall loss of 50 per cent for the two expansions. By suppressing the radio-frequency oscillator of a normal synchrotron for various time intervals and observing the effect on gamma-ray output, we find that the efficiency of electron capture can approach 100 per cent. This favourable correction can be explained by taking into account the build-up of the oscillations in the synchrotron resonator after a period of suppression.

We are indebted to Mr. D. W. Fry (Atomic Energy Research Establishment, Malvern) for the use of the 15-MeV. synchrotron for these experiments, which will be reported elsewhere.

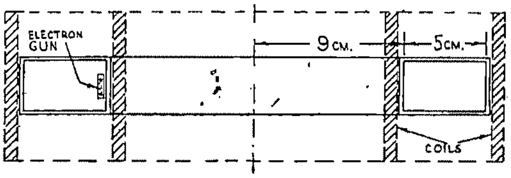

Fig. 1. Doughnut cross-section, with a possible coil arrangement shown dashed and shaded

The calculations for a small machine of this kind on the scale of Fig. 1 are given in the accompanying table with $f = 1{,}200$ mc./s., $\nu = 5$, and *H* varying as $1/r^{0\cdot5}$.

	Equilibrium radius	Energy	*H* (at Δ =10 cm.)	Δ *r*
Beginning of 1st expansion	9·95 cm.	0·080 MeV.	99 gauss	0·50 cm.
End of 1st expansion	12·43	0·148	123	
Beginning of 2nd expansion	9·95	0·148	138	0·40 cm.
End of 2nd expansion	13·28	0·430	228	
Beginning of 3rd expansion	9·95	0·430	263	0·25 cm.
End of 3rd expansion	11·92	—	—	

The sequence of events is also illustrated by Fig. 2, assuming that $dH/dt = 2\cdot5$ gauss/microsecond.

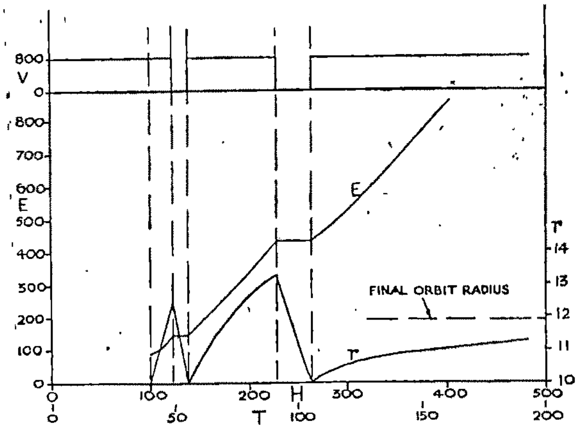

Fig. 2. Variation of resonator voltage *V*, equilibrium orbit radius *r* cm., and particle energy *E* keV., with magnetic field *H* gauss at 10 cm. radius and time *T* microseconds. Injection occurs at $H = 100$, $E = 80$ keV.

For a peak resonator voltage of about 800 volts, the range of stability in phase is about 340°, with an associated radial oscillation of amplitude given by Δr in the table.

Taking an intermediate estimate for the ratio of magnetic energy in working volume to total condenser energy as 1/3, we find that 10,000 joules stored energy will produce 85 MeV. electrons with a peak force on the coil of the order of 500 lb./in.[3] directed away from the accelerating region.

Renal Regulation of the Extracellular Fluid

THE behaviour of the kidney in relation to the electrolytes of the extracellular fluid is usually described in terms of two mechanisms operating to maintain the homœostatic state: (*a*) Regulation of the concentration of several individual electrolytes and non-electrolytes within a limited range of variability. The concept of 'renal threshold' is implied in this proposition. (*b*) Regulation of the osmotic pressure of the extracellular fluid, so as to maintain isotonicity with intracellular fluid.

A patient with a duodenal fistula was studied in some detail. He lost up to the equivalent of one quarter of the extracellular fluid of the body each day. The fluid from the fistula contained an average of 121 milli-equiv. per litre of sodium and 55 milli-equiv. per litre of chlorine. Thus there was an excess of 66 milli-equiv. per litre of sodium relative to chloride. In these circumstances, the level of sodium in the extracellular fluid would tend to fall by a greater amount per unit time than the chlorine, and the loss of this alkaline secretion would impose a severe strain on the *p*H control of the extracellular fluid.

The following observations were made: (*a*) Large amounts of chloride were present in the urine over a period of six weeks, during which time the level of chloride in the plasma was constantly below the accepted 'renal threshold'. (*b*) There appeared to be a commensurate variation between the quantity of chloride ion in the urine, and the volume of fistula secretion per day. (*c*) On the thirty-sixth day after the development of the fistula, the blood sodium and alkali reserve were restored to within normal limits by the intravenous administration of two-thirds of a gram molecule of sodium lactate, over a twelve-hour period. This caused a cessation of the large chloride excretion by the kidney. When the blood sodium fell again the chloride excretion recommenced. Over the time interval during which these variations occurred, the plasma chloride remained relatively constant at a level below the 'renal threshold'.

The most interesting feature of the findings was the relative constancy of the ratio of chlorine to sodium in the extracellular fluid, despite the continued loss through the fistula and from the body of 2–4 litres per diem of fluid containing approximately twice as much sodium as chloride. On the thirty-seventh day after the development of the fistula plasma, values were Cl = 82·7 and Na = 148·7 milli-equiv. per litre with the ratio $Cl_p/Na_p \doteq 0{\cdot}56$. Over the following six days 11·5 litres of fluid containing 766 milli-equiv. of sodium in excess of chloride were lost from the fistula. This is equivalent to 766/14 = 55 milli-equiv. of Na per litre of extracellular fluid, assuming this latter to have a volume of approximately 14 litres[1]. However, the ratio was $Cl_p/Na_p = 80/138{\cdot}3 = 0{\cdot}58$ at the end of the period. The probable explanation was the excretion by the kidney of fluid containing a sufficient excess of chlorine over sodium to maintain homœostasis. The cation used in this latter mechanism was predominantly potassium from intracellular fluid.

It would therefore seem possible that to account for the factors affecting the renal regulation of the quantity per unit volume of extracellular ions, it is necessary to consider plasma *p*H as a major variable.

It has become apparent that the maintenance of the equilibrium state within the tissue fluids in circumstances of disease is a basic problem of medical practice. Marriott, in the Croonian Lectures[2], has suggested that the quantity of chloride in the urine, as determined clinically by the simple Fantus test[3], can be used as a diagnostic criterion of the presence or absence of chloride depletion in the extracellular fluid. A correlation of the above observations with clinical phenomena to be described elsewhere would indicate the necessity of an experimental investigation to determine in what clinical circumstances the test is valid. It is suggested that the logical first step in clinical practice of ionic replacement therapy is qualitative analysis and quantitative record of the material which the body is losing.

Isophosphorylase and the Formation of Branched Polysaccharides

THE combined action of isophosphorylase and phosphorylase on glucose-1-phosphate results in the formation of branched polysaccharides like amylopectin and glycogen. Isophosphorylase is the enzyme which catalyses the formation of α-1,6-glucosidic links from glucose-1-phosphate as well as their phosphorolysis[1].

Whereas phosphorylase obtained from potato, yeast or muscle is strongly inhibited by phlorhizin, we have established that isophosphorylase from potato or yeast does not suffer any diminution in activity in the presence of phlorhizin (see table).

By adding phlorhizin to a mixture of phosphorylase and isophosphorylase, the activity of the former enzyme is diminished but not that of the latter.

Effect of phlorhizin on the action of potato isophosphorylase (phosphate buffer *p*H 6·6)

Concentration of phlorhizin	Degradation of residual dextrin by β-amylase	
	Isophosphorylase present	Isophosphorylase absent
0 $6{\cdot}0 \times 10^{-3}$ mol.	25 per cent 25 ,,	0 per cent 0 ,,

Thus the addition of phlorhizin brings about a change in the relative effective amounts of the two enzymes.

By allowing a mixture of potato phosphorylase and potato isophosphorylase to act on glucose-1-phosphate in the presence of increasing amounts of phlorhizin, we have obtained a series of polysaccharides which give with iodine a range of coloration from blue-violet, violet, purple to brown, that is to say, which have increasing degrees of branching, ranging from that of amylopectin to that of glycogen.

The degree of branching of the polysaccharide obtained by the combined action of phosphorylase and isophosphorylase depends, therefore, on the proportion of the two enzymes. The larger the relative amount of isophosphorylase the more branched is the polysaccharide formed.

We wish to thank Prof. K. H. Meyer for his interest in this investigation.

Microbiological Oxidation of Sterols

IN a previous communication[1], we described a method by which we oxidized cholesterol with *Azotobacter*. Our present experiments had a double purpose: (1) to limit the direction of the oxidation as narrowly as possible; (2) to work out a simple reproduction method, for our *Azotobacter* react with extreme sensitivity to antagonistic bacteria, so that their culture can be made only under the strictest sterile conditions.

For this double purpose we used bacteria which grow selectively on a certain medium, and investigated bacteria which decompose pyridine. We found that for oxidation of cholesterol *Proactinomyces roseus* was the most suitable[2]. This bacterium simultaneously decomposes the pyridine most effectively, and in the presence of a source of carbon multiplies fairly intensively. The presence of pyridine prevents the growth of other bacteria in the culture, so we could always carry out these experiments without any special sterilization. If we used cholesterol as source of carbon in the pyridine medium and aerated it for a suitable time, oxidation occurred and 7-oxycholesterol and cholestenone formed as oxidation products.

The formation of 7-oxycholesterol means that in the sterol series the $-CH_2-$ group can be oxidized to alcohol bacteriologically. As under suitably selected experimental conditions principally 7-oxycholesterol is formed, the results have a practical significance for the manufacture of the 'D_3' provitamin, as we succeed in obtaining it from cholesterol in very good yield in one step.

The experiments were made under the following conditions. We dispersed 0·5 gm. cholesterol in a litre of 0·2 per cent pyridine synthetic culture, and inoculated the mixture with *Proactinomyces roseus*. The culture was kept 14 days in a thermostat at 34° C. with constant aeration, and the pyridine used up was replaced from time to time. At the end of the cultivation period we extracted the medium with petrol-ether. The products were separated by chromatographic absorption on aluminium oxide. Besides the remaining minimal cholesterol we isolated as chief product 7-oxycholesterol and 4,5-cholestenone. Other oxidation products also formed in minimal quantities, identification of which is now in progress. We are continuing these experiments with *Proactinomyces roseus* in the sexual hormone series.

The Sommelet Reaction

IN a recent communication, Angyal and Rassack[1] show that the Sommelet reaction[2] is an oxidation-reduction process with the aldimine Ph.CH=NH as a probable intermediate,

$$\mathrm{PhCH_2NH_2 + PhCH_2N:CH_2 \xrightarrow{H_2O} PhCHO + NH_3 + PhCH_2NHCH_3},$$

and does not involve, as originally suggested by Sommelet[2], and stated by Graymore and Davies[3], prototropic conversion of methylenebenzylamine (I) to benzylidenemethylamine (II).

$$\text{(I)}\quad \mathrm{Ph.CH_2{-}N'{=}CH_2} \rightleftharpoons \left[\mathrm{Ph.CH \overset{\frown}{-N-} CH_2}\right]^- \rightleftharpoons \mathrm{Ph.CH = N - CH_3}\quad \text{(II)}$$

It is desirable to point out that this mechanism, now disproved, was inherently improbable. Ingold and Shoppee[4] showed that the methyleneazomethine system is one of the least mobile of triad prototropic systems; mobility in the phenylmethylene-azomethine system (I—II) is only achieved in the catalytic presence of hydroxide ions at 300° or of a considerable concentration of ethoxide ions at 190°, 2·92 *N*-sodium ethoxide in ethanol at ~ 85° being ineffective. These results were considered by Graymore and Davies, who, however, dismissed them with the remark that they are not comparable with those obtained by them in the presence of hexamine in dilute aqueous solution (boiling approx. 0·3 *N*-hydrochloric acid), and who state that under these conditions isomerization of methylenebenzylamine (I) to benzylidenemethylamine (II) ensues. While suitable prototropic systems are capable of catalysis by acids, methylenebenzylamine (I), like other Schiff's bases, is readily hydrolysed by hot dilute mineral acid[4]; even if, owing to the presence of an excess of formaldehyde, some proportion of methylenebenzylamine is always present under the experimental conditions used by Graymore and Davies, facile catalysis of a prototropic system so refractory as (I — II) under these conditions seems in the highest degree unlikely.

Graymore and Davies also suggest that the conversion of only some 10 per cent of methylenebenzylamine (I) to benzylidenemethylamine (II) in the presence of catalytic anions, reported by Ingold and Shoppee, is due to the removal of methylenebenzylamine (I) from the reaction by polymerization. It seems more probable that the proportion of isomerides, (I) 90 per cent : (II) 10 per cent, observed experimentally, is an example of the kinetic control of ion-recombination as opposed to the thermodynamic control of equilibrium, which is frequently encountered in prototropy and generally leads to the production of more than the equilibrium proportion of the thermodynamically less stable isomeride[5]. Owing to conjugation of the phenyl group with the double bond in (II) but not in (I), (II) is thermodynamically the more stable isomeride since the conjugation energy will contribute to its free energy. Neglecting other factors of a constitutional or environmental character, and taking the conjugation energy of the system Ph—CH=N· (for which no value appears to be available) as closely similar to that of the system Ph—CH=CH· (7 kilocal.)[6], it can be calculated using the relation $-\Delta F = RT \log K$ that the equilibrium proportion of (I) is about 0·005 per cent at 358° K., 0·008 per cent at 373° K., 0·03 per cent at 463° K. and 0·2 per cent at 573° K.; and, in fact, both at 190° and 300° C. the proportion of methylenebenzylamine (I) was too small for experimental detection[4].

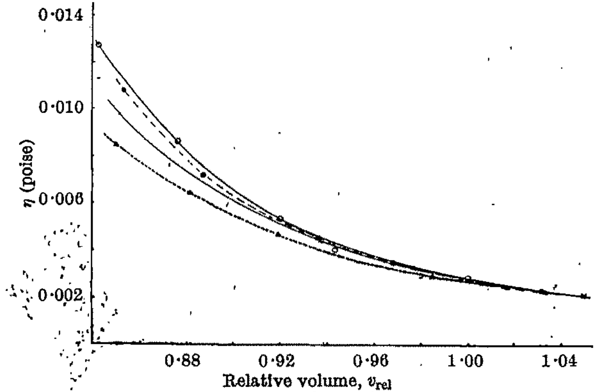
Viscosity-Volume Relation for Ether

It has recently been shown[1] that the theoretical expression for the viscosity of a liquid derived from Born and Green's[2] general kinetic theory of liquids consists of two parts, one due to the thermal motion of the molecules and the other to molecular attraction (that is, a volume effect). The latter effect greatly predominates.



O——O, 0° C.; ●····●, 20° C.; ×——×, 30° C.; ▲····▲, 75° C.

Experimental justification for this conclusion is provided by the accompanying isothermal viscosity-volume curves, calculated for ether, from the combined data of Bridgman[3] and Faust[4] on viscosities at high pressures. The temperature effect becomes progressively less as the volume increases until, in the region $v_{rel} = 1 \cdot 0$, it disappears completely. To the right of this point, the viscosity is a function of volume alone and is independent of temperature, and it is in this region that the empirical equation proposed by Batschinski[5],

$$\eta = \frac{c}{v - \omega},$$

where c and ω are constants and v is the specific volume, is so successful in representing observed behaviour.

Certainly in the case of ether above 0° C. therefore, and probably for many other liquids, the decrease in viscosity on heating at atmospheric pressure is a secondary effect, due entirely to expansion of the volume which in turn lowers the viscosity.

This is precisely the early view of the mechanism of the temperature variation of viscosity, first propounded by Warburg and von Babo[6] in 1882, and since then by many other authors, notably Batschinski (*loc. cit.*), which is now seen to be quite correct over the limited experimental range for which evidence was then available.

British Species of *Polycelis* (Platyhelminthes)

In 1884 Ijima[1] described *Polycelis tenuis* Ijima, a species which closely resembled the well-known *P. nigra* Ehrbg. More recently, interest in the legitimacy of this species has been shown by Continental workers, particularly Komarek[2] and Sekera[3]. These two authors agreed that both *P. nigra* and *P. tenuis* are good species; but they differed on the external features whereby the species might be distinguished. Lender[4] concluded that they could only be distinguished on the basis of internal anatomy and discounts such differences as shape of head, number of eyes and colour; he also regarded them as ecologically similar. Latterly, Tu[5] has questioned their separation as true species, but, like Lender, he found them in the same habitat on the Continent.

There is no mention in British literature of *P. tenuis*, all records referring to *P. nigra* or the distinctive *P. cornuta*. While studying the ecology of *Urceolaria* spp. (Peritricha) living on flat-worms[6], an apparent colour variety was noted which either carried few *Urceolaria mitra* v. Sieb. or none. This variety was distinguished by the much more uniform distribution of pigment compared with other worms in which the darker pigment occurred in blotches; that is, there was a pattern difference. Both types showed the usual colour range from yellow through brown to black. Fig. 1 records the population of *U. mitra* found on these two colour patterns—the uniform variety averaged 0·7 *Urceolaria* per worm, while the mottled variety averaged 22.

Examination of the reproductive organs of these two types showed that those with the uniform colour pattern agreed with *P. nigra*, whereas those with the mottling agreed with *P. tenuis*. These anatomical differences are quite marked[2,3,4] and relate to the shape of the penis, the type of spines carried on it and the presence or absence of musculo-gland organs. Fig. 2*a* shows the elongated penis of *P. tenuis* with about twenty rows of spines, mostly of a simple type

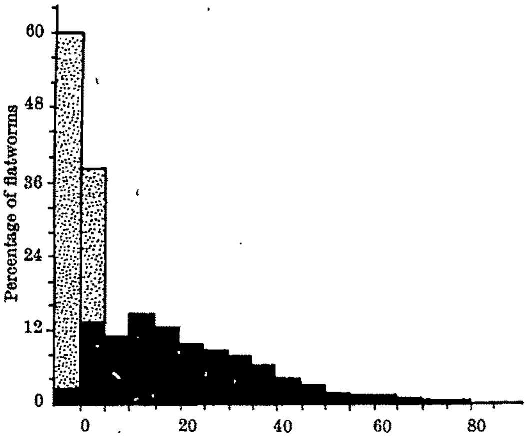

Fig. 1. Comparison of the Urceolarian population of the uniform (stippled) and mottled (black) varieties of flatworm

(Fig. 2*b*), Fig. 2*c* the shorter penis of *P. nigra* with four to eight rows of compound spines (Fig. 2*d*). The former has two musculo-gland organs. The worms referred to were taken from the College pond where the population of *P. nigra* is small compared with *P. tenuis*, in ratio about 1 to 28. The presence of *P. tenuis* has also been confirmed in a sample of flatworms from Lake Windermere kindly sent by Dr. T. T. Macan. Of 17 worms examined, 13 were *P. tenuis* and 4 *P. nigra*.

The discrimination shown by *Urceolaria mitra* suggests that the physiology and perhaps the ecology of the two flatworms differs. This is borne out by their distribution in the pond and behaviour in the laboratory. *P. nigra* occurs most abundantly near the inlet to the pond where the water moves slowly; *P. tenuis* prefers regions where the water is still. This is supported by examination of other habitats; for example, *P. nigra* occurs alone in a stream at Aber below the zone of *P. cornuta*. There may also be differences in the type of pond the two species favour, but overlap occurs. In the laboratory under conditions resembling a pond habitat rather than a stream, *P. tenuis* thrives much more than *P. nigra* and produces cocoons more freely.

P. nigra has been a favourite type for physiological work, and also figures in many ecological surveys. It is conjectural to what extent it has been confused with *P. tenuis* in the past, in Great Britain, and how this may have affected conclusions. If, as I suggest, the two species can be distinguished on colour pattern, then they can be easily separated under the binocular microscope. This only becomes difficult when the worms have fed heavily and are distended.

Determination of Plant Densities

E. J. MACHIN[1] appears to be unaware of the extensive study by G. E. Blackman[2] on the relation between plant density and percentage absence. In a theoretical appendix to this paper, I have pointed out that the most efficient size of quadrat corresponds to about 20 per cent absence, or a product of quadrat size and plant density of about 1·6 (the efficiency remains reasonable over a range of, say, 0·7–3·0, compared with the rather wider range 0·3–3·3 implied by Machin).

It should also be noted that, while the method is only applicable as an exact method when the distribution of plants is random, it may be used in the more general class of cases for which the relationship between the logarithm of percentage absence and plant density is still linear to provide a comparative index of abundance.

Groundnut Breeding

IN view of the increasing economic importance of the groundnut, a new investigation of its chromosomes should be made known at once. Mendes[1] reports from São Paulo that *Arachis diogii*, *A. marginata*, *A. prostrata*, and a cultivated form from the Mato Grosso, all have 20 chromosomes, the previously known species and cultivated forms[2] all having had 40. Evidently the cultivated forms are mostly tetraploid, and their diploid ancestors are now revealed to us for the first time. The tetraploidy of the groundnut may well have arisen at an early stage of its peregrination when it passed from Brazil to Peru in pre-Columbian times[3].

The diploid species now offer us a ready means of protecting our very vulnerable groundnut industry from disease if we are willing to enrich the store of available variation in this hitherto unresponsive crop by crossing with the new wild sources.

ANTI-TUBERCULAR ACTIVITY OF OXIDATION PRODUCTS OF SUBSTITUTED *o*-PHENYLENE DIAMINES

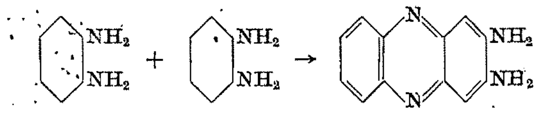
By DR. VINCENT C. BARRY, J. G. BELTON, M. L. CONALTY and D. TWOMEY

Department of Chemistry, University College, Dublin, and School of Pathology, Trinity College, Dublin

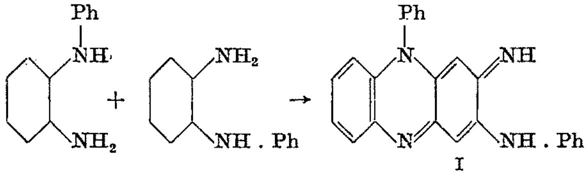
AS reported in an earlier communication in *Nature*, we have been examining the anti-tubercular properties of substituted diphenyl ethers and related compounds[1]. In extending this study to include diphenylamine derivatives, a curious phenomenon was encountered with 2-aminodiphenylamine. When freshly prepared, an aqueous solution of the hydrochloride of this base completely inhibits the growth of *Myco. smegmatis* at a dilution of 1/100,000. On keeping, and occasional warming, the inhibitory power of this solution increases gradually, the five weeks old solution producing complete inhibition at a dilution of 1/1,000,000. At the same time it was noticed that the colour of the solution rapidly changed from an initial pink to a very dark red. The highly coloured product formed in the solution was obviously of great interest. It was afterwards found that addition of ferric chloride solution to an acid solution of the base produced an immediate deep red coloration and separation of a dark crystalline precipitate. This proved to be the hydrochloride of a base, $C_{24}H_{18}N_4$, from which the base itself was liberated by ammonia in the form of a brick-red crystalline powder.

When tested in broth against *Myco. smegmatis* and *Myco. tuberculosis* (*H37Rv*), the dye salt proved to have a remarkable biological activity. Complete inhibition of growth of the former for six days is produced at a dilution of 1/1,500,000 and of the latter for 42 days at 1/20,000,000. The activity is retained to a considerable extent in the presence of five per cent pooled human serum.

A subsequent search of the literature showed that the rapid acquisition of a red colour by solutions of 2-aminodiphenylamine salts had been noted frequently, and a number of workers had investigated the oxidation of this aromatic base with ferric chloride[2-8]. Kehrmann[9] showed that the oxidation of *o*-phenylenediamine with ferric chloride yielded 2 : 3-diaminophenazine, the formation of which he explained as shown :



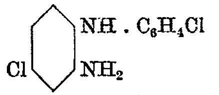
Fischer and Dischinger[8] maintained that the oxidation of 2-aminodiphenylamine followed on the same lines.



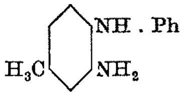
I

Analyses and molecular weight determinations of (I) as prepared by us agree with the above formula.

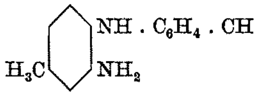
With the view of confirming the mechanism of the oxidation as outlined above, 2-aminodiphenylamine derivatives carrying a substituent in the aminated ring in the position *para* to the NH— bridge were oxidized under similar conditions.



II

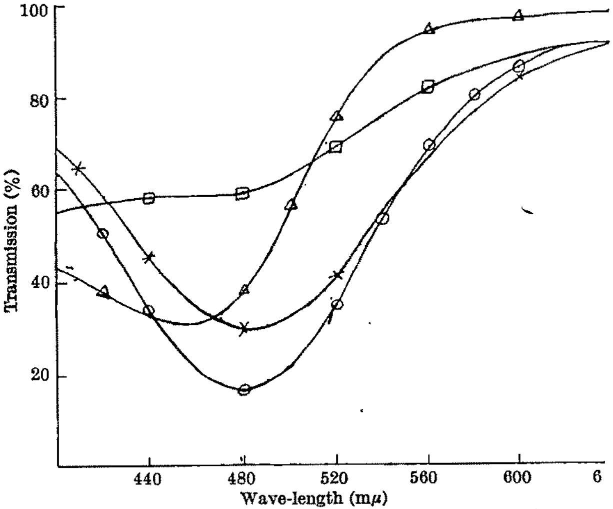


III



IV

(II) gave a pigment showing similar colour reactions to (I), and on analysis proved to have lost one chlorine atom in four during the oxidation. This compound could only have formed a pigment of this type by loss of chlorine. (III) and (IV), containing stable *para* substituents, gave highly coloured products also ; but these showed different colour reactions and absorption curves, and had low antitubercular activity. They clearly belong to a different class from (I) and constitute further evidence in favour of Fischer's formulation.



Pigments from : ⊙, 2-aminodiphenylamine ; ×, 4 : 4′-dichloro-2-amino-diphenylamine ; □, 4-methyl-2-aminodiphenylamine ; △, N-methyl-*o*-phenylene diamine

Further pigments were prepared from mono-, di- and tri-chlorinated 2-aminodiphenylamines, the chlorine atoms being substituted in the ring not carrying the —NH_2 group. As expected, these were very highly coloured, and their absorption curves and the colour exhibited by them in strong mineral acid resembled closely that of (I). As seen in Table 1 however, the antibacterial activity is low when th molecule contains more than two chlorine atoms. Th loss of activity in these molecules may be due t alteration in the lipoid/water solubility ratio consequent on the higher degree of halogenation.

When (I) was given in the feed to guinea pig experimentally infected with tuberculosis (Ravene *Rv* strain), at a dosage of 33 mgm. per day, it had n effect on the course of the infection. None of th pigment was excreted in the fæces of these animals and it is possible that it was decolorized by th intestinal flora. *In vitro* tests with (I) against *B. col*

Table 1. The numbers represent the dilutions which cause complete inhibition of *Myco. smegmatis* for 6 days and *Myco. tuberculosis* for 42 days

Pigment from	*Myco. smegmatis*	*Myco. tuberculosis*	
		Without serum	With 5 per cent serum
	1,500,000	20,000,000	3,000,000
	2,000,000	3,000,000	2,000,000
	20,000	25,000	—
	5,000	50,000	—
	200,000	2,000,000	1,000,000
	5,000	300,000	50,000
	5,000	50,000	50,000

showed that it had no inhibitory effect on this organism at 1/5,000, but that it was decolorized by he bacteria. Subcutaneous or intramuscular injecion of the hydrochloride of (I) in guinea pigs in doses of 5–35 mgm. produced severe local toxicity, and this node of administration could not be continued. Intravenous injection in rabbits proved rapidly fatal. When 2-aminodiphenylamine hydrochloride is oxilized by ferric chloride in the presence of human serum, a very deep red pigment is formed which does not separate. Menkin[10,11] has successfully administered ferric chloride intravenously. In view of this and in the hope that the toxic effect might be reduced f the pigment were produced in the blood stream, rabbits were injected intravenously with 2-aminodiphenylamine (15 mgm., 2 c.c.), followed by ferric chloride (15 mgm., 6 c.c.). The rabbits died, however, after an average total quantity of 100 mgm. of 2-aminodiphenylamine had been given over a period of fourteen days, a quantity comparable to the amount of (I) which had already proved lethal intravenously.

Table 2. Antibacterial activity of the pigment (I) from 2-aminodiphenylamine. The figures given in the third and fourth columns represent the dilutions which cause complete inhibition of growth

Organism	Period of growth (days)	Inhibitory dilution in broth	Inhibitory dilution in broth + 5 per cent human serum
Myco. tuberculosis	42	20,000,000	3,000,000
Myco. smegmatis	6	1,500,000	1,500,000
Corynebacterium diphtheriæ (mitis)	3	7,500,000	60,000
Staph. aureus	3	200,000	< 60,000
Strep. fæcalis	3	100,000	10,000
Strep. pyogenes	3	200,000	< 60,000
Strep. viridans	3	80,000	20,000
Vibrio 10	3	10,000	10,000
B. typhosus	3	80,000	5,000
Bact. coli	3	< 5,000	—

While it is clear that the high toxicity of (I) for animals renders it unsuitable for therapeutic use, it may be possible to reduce the toxicity of this structure without destroying its antibacterial power. This might be achieved by increasing the solubility of the pigments by including an OH, COOH or similar group in (I), or alternatively by synthesizing pigments of lower molecular weight. The pigment produced from N-methyl-*o*-phenylene diamine (Table 1) has very high activity against the tubercle bacillus, and its toxicity to animals should be lower than that of (I). These alternatives are being investigated.

These synthetic pigments are of added interest because of their relation to the bacterial pigments, pyocyanine, chlororaphin and iodinin, all of which are phenazine derivatives. Also Iland has reported recently on the high antitubercular activity *in vitro* of N-oxides of phenazine[12].

This investigation is being conducted and financed by the Medical Research Council of Ireland, to which grateful acknowledgment is made. The strains of *Myco. tuberculosis* used in these experiments were provided by the Trudeau Foundation. Our thanks are due to Mrs. E. Philbin for assistance.

TENTH INTERNATIONAL LIMNOLOGICAL CONGRESS, ZURICH

THE International Association for Theoretical and Applied Limnology, the object of which is to provide a common meeting ground for those interested in the biology and utilization of fresh waters, achieves its purpose by means of congresses which are ordinarily held every two years and the proceedings of which are afterwards published. Between successive congresses, matters requiring attention are dealt with by the president, the secretary and a small executive committee, while reference can also be made to the members of an international committee upon which each participating country has one or more representatives. The last congress met in Sweden in 1939 and, apart from all other considerations, that held this year in Switzerland will be memorable for the renewal of old friendships and the opening up of new avenues of scientific intercourse. It was attended by about a hundred and sixty individuals representing twenty-one different nations, and the British group was one of the largest.

The opening session on the first evening, at which formal business tempered by interludes from a first-class string quartette was transacted, was held in the spacious Zurich Congress House. On this occasion Naumann Medals, which are awarded for distinguished services to limnology, were presented to the American Society for Limnology and Oceanography and to the Freshwater Biological Association of the British Empire. The evening concluded with a supper, at which the Swiss organising committee were our hosts, and which served to a remarkable degree to establish contact between the different nationalities present.

The scientific work of the Congress was largely concentrated into the mornings of August 19 and 20 and the morning and afternoon of August 22. On each occasion there were simultaneous sessions concerned with general limnology and with freshwater fisheries, while on August 22 there were other sessions devoted to water utilization and water sanitation. The many short papers read at these various sessions, a considerable number contributed by the British members, covered a wide range of topics. The ecology of river-populations and self-purification in rivers, phytoplankton problems and the fungal parasites of the phytoplankton, the ecology and distribution of diverse freshwater Invertebrata, the regional limnology of Switzerland, seasonal changes at the mud-surface and detritus-drifts in lakes, fish-culture and sex in fish, the chemistry of sewage disposal waters, and the biology of filters were among the numerous subjects discussed. There were also several lectures on major topics. Of quite special interest, in view of its relation to the many lakes visited on the excursions, was the symposium on the recent development and present biological condition of the lakes bordering the Alps, in which Profs. Jaag (Zurich), Baldi (Pallanza), and Ruttner (Lunz) took part. On August 20 Profs. Steinmann (Aarau) and Willer (Hamburg) dealt with the taxonomic problems afforded by the genus *Coregonus*, discourses which proved of great interest even to those not directly concerned with fisheries, while on August 22 F. W. Mohlman (Chicago) gave an account of recent developments in industrial waste disposal. On this, the last evening in Zurich, the Town Council entertained the members of the Congress to dinner.

The excursions, which were designed to illustrate much of the matter that had been discussed during the scientific sessions, were excellently organised and were marked by the lavish hospitality that accompanied them. The afternoons of August 19 and 20 were devoted respectively to a visit to the Cantonal Fish Breeding Station at Stäfa, and to a trip by motor coach to various small lakes in the vicinity of Zurich. The whole of August 21 was taken up by a visit to the falls of the Rhine at Schaffhausen and to the "Untersee" (Lake of Constance), while on August 24 most of the members visited the laboratory on the Jungfraujoch. Both these full-day excursions were favoured by good weather and must have left a deep impression on the participants. On August 23 we travelled from Zurich to Interlaken via Lucerne and the Brünig Pass, making a stay of several hours at Kastanienbaum to visit the small but well-equipped hydrobiological station, originally founded by H. Bachmann and now maintained by the Natural History Society of Lucerne. The latter very generously entertained us to lunch.

The concluding session on August 25 was held at Montreux. Dr. Gunnar Alm (Drottningholm, Sweden) was re-elected president of the Association, while Dr. Rohde (Uppsala) was elected secretary in succession to Prof. Lenz (Plön), who had filled this office since the foundation of the Congress in 1922. It was decided that the next congress should meet in Belgium in 1950, and the ensuing one in Britain in 1952.

It is impossible to say too much in praise of the general organisation that rendered the Congress so unqualified a success, or in acknowledgment of the generosity that made so much available to the members for so small a financial outlay. Among the many Swiss men of science who were concerned, special mention should be made of the head of the Organising Committee, Dr. Huber-Pestalozzi, and of his associates Prof. O. Jaag and Dr. U. Corti, while Mrs. Minder, though never to the front, was a help and guide to all participants.

F. E. Fritsch

SEMICONDUCTORS AND THEIR APPLICATIONS

The summer meeting of the Manchester and District Branch of the Institute of Physics at the University of Manchester took the form of a two-day conference on semiconductors and their applications. The chairman of the branch, Prof. E. G. Cox (Leeds), presided.

The purpose of the conference was to bring together those working on the fundamental physics of semiconductors, those making such substances commercially, and those applying them in various branches of science and engineering.

The opening session was concerned with the fundamental theory of the behaviour of electrons in semiconductors. Dr. J. W. Mitchell, of the University of Bristol, began by distinguishing between conduction in metals, in semiconductors and in insulators. In semiconductors, conductivity increases with temperature and with the amount of impurity present. The characteristic relation between conductivity, σ, and absolute temperature, T, is

$$\sigma = ae^{-E/kT}, \qquad (1)$$

where E is an activation energy. Dr. Mitchell then developed most concisely the wave-mechanical concepts of electrons in ionic crystals and the conditions obtaining in periodic lattices which lead to the splitting of allowed energy-levels for the electrons into large numbers of closely spaced levels, that is bands. The effects of the presence of defects and impurities in such a lattice were considered, and the distinctions between excess (n-type) and defect (p-type) semiconductors made clear. In the first type the carriers of charge are electrons, and in the second they are 'positive holes'. For example, sodium chloride when heated to 600° C. in an atmosphere of sodium vapour turns orange, due to the formation of 'F-centres', and at 300° C. under the influence of an electric field the coloration moves towards the anode. With potassium bromide after heating in an atmosphere of bromine, under an applied field the coloration moves toward the cathode. The coloured materials behave as n- and p-type semiconductor respectively. Much of the work on the properties of alkali halides had been carried out by Pohl at Göttingen, and Dr. Mitchell emphasized the importance of such work on relatively simple lattices in gaining an understanding of the behaviour of more complex semiconductors.

Lead sulphide can be given semiconducting properties either by heating in sulphur vapour, in which case it becomes a defect or p-type semiconductor, or by heating *in vacuo* (giving an excess semiconductor). Barium oxide when heated in barium vapour turns orange-yellow due to the production of F-centres. The oxides of titanium, zinc, cadmium and aluminium when heated *in vacuo*, and cuprous oxide, nickel oxide and uranium dioxide when heated in excess oxygen, all show semiconductor properties. Finally, Dr. Mitchell considered magnetite, a substance the conductivity of which (200 ohm^{-1} cm.$^{-1}$) lies approximately midway between that of a metal and of the average semiconductor. Its unit cell is twice the size of the normal cell and includes 32 oxygen ions and 24 iron ions. Of these 24 iron ions, 16 are ferric and 8 ferrous. Consideration shows that 8 of the ferric ions can be considered as 8 ferrous ions each with an extra electron, thus giving rise to additional energy-levels above the normal filled band and so accounting for its conducting properties.

Dr. R. A. Smith (Telecommunications Research Establishment, Malvern) then followed with a paper dealing principally with conductivity measurements. Previous work indicated that a of equation (1) varies to some extent with amount of impurity, and E varies considerably. Also there is a difference between measurements made on polycrystalline samples and those on single crystals of the same substances. Plots of log σ against $1/T$ give straight lines, the slopes of which decrease with increasing quantity of impurity. In most substances, measurements of Hall coefficients and thermo-electric powers have shown that conductivity is by electrons or by positive holes. For others, notably lead and tin sulphides, conductivity can either be by electrons or positive holes, depending on whether there is excess of metal or electronegative constituent, and near the stoichiometric composition the number of carriers of each type is approximately equal. In the latter case, the conductivity is a minimum and the temperature coefficient a maximum. For polycrystalline materials conductivities range from 10^{-8} to 10^{-2} ohm^{-1} cm.$^{-1}$; but for single crystals the range is 10 to more than 1,000, and the temperature coefficient is small and usually slightly negative. Single crystals thus appear to behave as semi-metals. The difference between single and polycrystalline materials might arise through the presence of intercrystalline barriers, and to investigate this, R. P. Chasmar has made measurements at the Telecommunications Research Establishment on evaporated layers of lead sulphide at radio frequencies up to 50 Mc./s. The results are difficult to interpret, but it appears that at high frequency the temperature coefficient of conductivity is small and negative, while at low frequency it is large and positive.

Dr. G. G. Macfarlane (Telecommunications Research Establishment) spoke about some theoretical aspects of the work done on lead sulphide cells, especially the variation of resistance at low temperature. He explained the form of the resistance-temperature curve by assuming that at low temperatures (below 150° K.) the supply of electrons is constant, independent of temperature, but that their mobility varies with temperature.

Dr. C. J. Milner (B.T.H. Research Laboratory, Rugby) described and demonstrated various recently developed semiconductor devices useful in infra-red work and now available. A 'coolable' type of lead sulphide photoconductive cell with 10 mm. × 1 mm. element size has a detection limit (signal equal to noise for 1 c./s. band-width) of 5×10^{-10} watt at 20° C. and 5×10^{-11} watt at $-$ 80° C. (that is, filled with solid carbon dioxide). At 20° C., peak spectral response is at $2{\cdot}2\,\mu$ and the long wave limit at about $3{\cdot}0\,\mu$; at $-$ 80° C., $2{\cdot}8$ and $3{\cdot}4\,\mu$ respectively. Bolometers formed of (reduced) magnesium titanate are able to detect about 10^{-6} watt/cm.^{2}; a unit with element size 2 mm. × $0{\cdot}2$ mm., suitable for spectrometer use, has been standardized. The sensitivity of these types of detector in radiation pyrometry is comparable for source temperatures of 100–200° C. Nernst filaments (zirconia rods with platinum leads) operating as radiation sources at 2,000–2,100° C. in free air were also shown.

Dr. Milner referred to the theory of Sosnowski, which explains the experimental result of Starkiewicz and others, that maximum photosensitivity in lead sulphide coincides with zero (overall) thermo-electric power, by identifying this state as that giving maximum frequency of alternation between n- and p-regions. He suggested that the theory also associated high sensitivity with an uneven distribution of impurities, and that this might explain the wide variations encountered in processing evaporated cells.

Dr. R. W. Sillars (Metropolitan-Vickers Electrical Co., Ltd.) gave a paper on non-linear resistors, in which he dealt with the properties of silicon carbide. Polycrystalline silicon carbide bonded by clay showed non-linearity of its current-voltage relationship and other properties quite different from specimens of sintered silicon carbide. Besides demonstrating these properties he outlined methods of using such semiconductors as circuit elements.

Mr. H. Wolfson (Standard Telephones and Cables Co., Ltd.) presented a paper on thermistors in which he began by reminding his audience of the researches of Faraday on the properties of silver sulphide over a hundred years ago, and the development which has taken place up to the present time. The use of silver sulphide was abandoned some years ago because of the occurrence of polarization effects due to ionic conduction and the presence of a 'hysteresis' loop when temperature changes occur. At the present time the most common materials used are the oxides of cobalt, manganese, nickel, iron, chromium and copper. In production, beads of the oxides, mounted on fine platinum wires, are fired in controlled atmospheres. Typical thermistors have a 'half-temperature' of 20° C. at 300° K., that is, a temperature change of 20° C. at 300° K. will double or halve the electrical resistance of the bead. Another type of bead has a cold resistance of 2,000 ohms, but if 20 milliwatts is dissipated in the bead its resistance will fall to 60 ohms. The use of thermistors as circuit elements was described, as well as some of their applications in medical research as temperature indicators.

Dr. H. L. Penman (Rothamsted Experimental Station) described the development of a portable thermistor bridge for micro-meteorology among growing crops. A portable unit had been built to measure temperature, humidity and wind speed among growing potato-crops in connexion with an investigation into factors affecting the spread of virus disease.

Mr. S. L. Martin (Philips Electric, Ltd., London) described recent experiments carried out by Vink on the conductivity of mixed barium and strontium oxides, which were explained in terms of conduction through crystallites in contact and thermionic emission from crystallite to crystallite. The curve of conductivity as a function of temperature showed three different slopes for the temperature ranges, less than 700°, 700–800°, and above 800° K., the values agreeing with those previously reported. In discussion, the need for consideration of much simpler substances was emphasized as well as the elimination of uncontrollable variables, and it was suggested that magnesium oxide would be the easiest oxide to study since large single crystals have recently become available.

Photo-conductivity of the lead sulphide type of semiconductors attracted some discussion, especially as the literature appeared to indicate that the method of preparation of the lead sulphide films affected considerably their photo-conducting properties. It was suggested that the lead telluride type of cell should be studied since its production does not involve contamination by oxygen, etc.

The final session of the Conference was devoted to an exhibition of properties and applications of semiconductors, many of which had been discussed in the main sessions. A clutch using the Johnson–Rahback effect was shown using polished magnesium titanate in contact with polished brass, as well as a lead sulphide cell showing the high temperatures reached at hot spots at frictional contacts.

The papers and discussions made clear the growing interest in the theory and applications of semiconductors, and directed attention to the work proceeding in government, industrial and university laboratories. Some of the papers presented will lead to contributions to other journals.

F. A. VICK

SELECTION OF STUDENTS FOR UNIVERSITIES

ON the morning of September 14, Section L (Education) of the British Association discussed "Selection at the University Level". Mr. W. O. Lester Smith, president of the Section, presided.

Mr. J. O. Roach spoke from experience of the Civil Service Selection Board, and previously as a Cambridge tutor. He said that some well-known modern methods of selection depended essentially on a careful job analysis. But in the case of university students, for what were we selecting ? For success in examinations, for success in life, or for what ? There was no one criterion and therefore no one method of selection. He felt strongly himself that there must on no account whatever be any interference with those of exceptional intellectual powers; no non-academic criterion must be allowed to exclude these. Also he was against a health test—too many men of intellectual distinction had suffered from poor health since the beginning of the world. Forecasts of employability, too, were extremely difficult to make successfully. We must not exaggerate the ill-success of the present method; at least it satisfied public opinion as non-political and generally fair. Still, methods of selection were certainly an important problem, now that there was hope that all, or nearly all, the boys and girls of ability in the nation would reach the sixth forms of schools; and the dissatisfaction with to-day's students expressed by Lord Lindsay of Birker in the House of Lords had met with wide agreement. Mr. Roach emphasized that the need for a new approach was being widely recognized in the universities; and he warned the meeting against assuming that there was any one quick and easy solution to be found.

Mrs. J. L. Stocks found wide agreement among those present with views she had formed from her experience at Westfield College, London. There she had, with very small exceptions, been concerned only with honours women students for arts subjects. She thought that there was a serious danger of paying too much attention to the requirements of the various professions, and too little to the quality of life inside universities. She was herself impressed with the qualities of to-day's women students, who were drawn from a wider range than the students of the '90's, with their cultured, keen but rather narrow backgrounds. In the sixth forms of schools nowadays, the girls had done all sorts of things outside formal classes, from dramatics and foreign visits to conferences on world citizenship and the organising of national savings. They had their shortcomings, of course; some of them, for example, had no idea how to talk to a stranger or how to go away from a party.

As for the present system of selection, Mrs. Stocks said there was rather an absence of system. The anxious queueing for Somerville, Westfield and other residential colleges was a ridiculous arrangement, infuriating for the selectors and very bad indeed for the adolescent selectees. She thought that any better method of selection would be likely to involve some degree of conflict with hitherto accepted individual liberties; but this might have to be accepted. A final solution might well take time to find, as the encouraging success of social democratic education was still a new thing. At all costs, universities must remain academic communities, and not become, for example, mere schools for leadership.

Mr. C. R. Morris spoke as a headmaster. He did not believe that the selection of individual students was the most important problem to-day, urgent as it was. The universities appeared to be dissatisfied with nearly all the students they were admitting, and not just with the small percentage of the total body who might be different if the system of selection were different. As a result, many people seemed to be toying with the idea that able boys ought to continue right up to the age of eighteen with work on the general type of school certificate work. If this were really intended, it would be a very serious mistake. It had been a great triumph on the part of the grammar schools to lead so many good students to the doors of the university and make the present university expansion possible. It must not be supposed that all able boys *wanted* to go to the university. Outside the professional and near-professional classes this was far from being the case. In the other sections of society, it was the schools which had to do the missionary work, and without doubt it was by their sixth-form courses that they succeeded.

Moreover, this sixth-form work, Mr. Morris claimed, was in principle educationally sound. After reaching the age of fifteen or so, an able boy, whose contemporaries were starting on their working careers, needed to feel that he was beginning to become a real scholar or expert in the group of studie for which he had the best aptitude. This gave him his initiation into the commonwealth of learning. Certainly his work in his special field ought to have a less crowded syllabus than at present and give him more elbow room to explore for himself; and outside his special field he should give a third of his time and energy to the continued study of the use of English and to the discussion of general problems, cultural, religious and social. Discussion really came to mean something if each boy could contribute to it on the basis of his own expertise and hear his friends do the same. Ideally, sixth-form work, outside the subjects of special choice, should not be subject to external examinations. It was necessary here to exploit idiosyncrasies in the teachers, not to steamroller them. The most important single thing was a real understanding between teachers and schools, and this would now be perfectly practicable if it were set about in the right way.

In the course of an interesting discussion, Mr. Clegg made the point that local education authorities had in effect asked the universities to organise through the joint matriculation boards the selection of students for financial grants, and the universities were now criticizing the students selected. The remedy, he thought, lay in the hands of the universities themselves.

The president of the British Association, Sir Henry Tizard, said that in his view university teachers should recognize that they were not experts in the education of schoolboys and schoolgirls, and should leave this to the schools. University students must be in the upper range of intelligence and must *want to do something.* Intelligence and zeal—provided students had these virtues on entering the university, it did not matter what subjects they had been taught at school.

A number of speakers emphasized that public opinion did not sufficiently appreciate the part that ought to be played in the higher education of the nation by technical colleges. It was most shortsighted to allow these to continue to fall so far short of the universities in prestige.

MORPHOLOGICAL ASTRONOMY

THE Halley Lecture for 1948, with the above title, was delivered at Oxford on May 12 by Dr. F. Zwicky, of the California Institute of Technology, Pasadena. The lecture covers such a wide range in astronomy that only the more important points can be referred to in this short summary; fuller information can be obtained from *The Observatory* (68, 845, August 1948), where it is printed in full.

The morphological method is merely an orderly way of looking at things, and its essence is direct thinking and direct action—a combination which is a great asset of free men and of the democratic way of life. A complete morphological analysis of astronomy is a very comprehensive undertaking, and Dr. Zwicky discusses only some of the basic elements of uch an analysis, among which he includes the following: observation of celestial phenomena; experimentation with celestial phenomena; theoretcal integration; use of the knowledge gained in onstruction; dissemination of the knowledge and ts bearing on all activities of man.

Under the first of these headings, Dr. Zwicky deals with the instruments to be used for observation and gives a very brief description of the photo-electronic elescope, which has introduced a number of new features. Even with such telescopes of relatively mited definition and light power, the search for ovæ, supernovæ, variable stars, comets, meteors, etc., can be put on a 'mass-production' scale because images from photo-electronic telescopes can be televised. Another of the different advantages of this telescope is the ability to steady moving or scintillating images resulting from unsteadiness of the atmosphere or motions in the telescope, and automatic guiding of the telescope can be accomplished through devices similar to those used for steadying the refocused image on the recording surface.

Reference is made to the devices for observing phenomena from points above the main portion of the earth's atmosphere, by the use of rockets carrying scientific instruments. V2 rockets have already carried various instruments to heights exceeding 200 km., and it is proposed increasing this range to 1,000 km. to eliminate the greater portion of the atmospheric absorption. There are visions of vehicles carrying observers to great heights, and even the high-flying conventional aircraft have possibilities in this direction which may some day be exploited.

The accomplishments of the 18-in. Schmidt telescope on Palomar Mountain during the last ten years are dealt with, and important results mentioned refer to work on clusters of nebulæ, nebulæ, stars, supernovæ of various types, common novæ, very blue faint stars, and the general theory of relativity and the theory of the expanding universe. In connexion with this last subject, it was proposed that compact nebulæ acting as gravitational lenses could be used as a check for the deflexion of light, and the idea of nuclear matter of a density of the order 10^{14} gm./c.c. was also suggested. Such matter, which should exist in neutron stars—perhaps ancient remnants of supernovæ—would act as gravitational stars *par excellence*, and it is intended to make a determined search with the 18-in. Schmidt. Bright supernovæ supply data for some interesting conclusions on nuclear chain reactions, knowing that such bodies emit during the first 200 days about 5×10^{48} ergs in the form of visible light. For a star of mass 100 times that of the sun and containing about 10^{59} protons, the energy liberated per proton is, therefore, much greater than the maximum energy liberated per proton in the most energetic chemical reaction. There is, therefore, some justification for the conclusion that in a supernova outburst there is a nuclear chain reaction attended probably with a gravitational collapse to nuclear matter. Some supernovæ, notably the object NGC 4636, have been caught on the rise, and in such cases the speed is in accord with the assumption of nuclear chain reactions. As Zwicky remarks, "We here therefore have one more example how apparently academic astronomical observations led the way to the discovery of phenomena of the greatest import". A short investigation suggests that there is the possibility that cosmic rays are generated in supernovæ.

Astronomical knowledge has been used in the past for the conduct of human affairs, and an extrapolation of these applications, which lies in the line of morphological thinking, is a reconstruction of the universe, in which that of the earth comes first. This is of fundamental importance as there is the danger that the whole earth might be exploded by large-scale nuclear chain reaction, and schemes for stabilizing the earth against such an eventuality are part of morphological astronomy. Possibly there will also be plans for making some of the planets habitable by changing them intrinsically and by altering their positions relative to the sun; and however fantastic such schemes may seem, Zwicky suggests that these thoughts are nearer to scientific analysis and mastery than were Jules Verne's dreams in his time.

The aim of the universities is to produce astronomers, chemists and so on; but this approach has failed us, especially if it is admitted that the purpose of education is the creation of realities that are in agreement with the avowed purpose of man. The purposes have frequently been stated, but the actualities present a state of affairs in which it is often difficult to recognize them. In the morphological reconstruction of human society and the material universe, astronomy and astronomers may be destined to play an important part.

SOCIAL SCIENCES AND INDUSTRIAL PRODUCTIVITY

BESIDES discussing the place of science in government and scientific man-power (see *Nature* of August 7, p. 199), the first annual report of the Advisory Council on Scientific Policy gives some account of the work of the committee set up to report to the Advisory Council regarding the directions in which a scientific approach is most likely to promote an increase in the national productivity. In an interim report submitted in September 1947, the committee concluded that current fundamental research in the physical and biological sciences was unlikely to have any material short-term effect in increasing productivity, whatever might emerge from its results in future. For short-term results the more effective application of scientific knowledge already available was likely to prove much more fruitful; but for this an adequate supply of qualified technologists and engineers is essential. The committee recommended that steps should be taken immediately to ensure that this demand is met. It was also suggested that the type of approach used so successfully by the Services during the War and commonly described as 'operational research' might also be very fruitful in yielding rapid results. Publication of a book on operational research was recommended and its preparation is in hand. The committee also suggested that it is important to try to establish scientifically whether the quantity and quality of the existing rations are likely to diminish the worker's potential outlook. Later, it strongly recommended the energetic pursuit of research on the nutritional consumption and physiological requirements of the main occupational classes in the United Kingdom, as well as obtaining relevant data from abroad, particularly from the United States and from the British Zone of Germany.

The Committee on Research and Productivity also appointed a special sub-committee to review existing technical information services and to consider their improvement. The work of this sub-committee was afterwards transferred to a Panel of the Committee on Industrial Productivity. It has been decided that the Information Unit in the Intelligence Division of the Department of Scientific and Industrial Research should be expanded to provide a national service for putting inquirers into touch with sources of specialist information. The possibility of achieving rapid results by the application of sociological principles was likewise explored. A memorandum issued on the human factor in production recommended a review of existing knowledge in this field, more effective co-ordination of the work being carried out by different bodies and further research into the basic conditions of good morale and efficient organisation, the characteristics of successful joint production committees, the status and position of the foreman, the differences of response as between male and female operatives, and the selection and training of managerial staff. It emerged in this general inquiry that the concrete objective of raising the level of the least efficient firms nearer to the level of the most efficient would go a long way towards effecting the general rise of ten per cent in overall output by British industry for which the Government had asked. The functions of this Committee have now, as announced last December, been transferred to the new Committee on Industrial Productivity, which, with its four subsidiary panels, is continuing and extending the work initiated under the Advisory Council.

This new Committee is quite independent of the Advisory Council on Scientific Policy, but Sir Henry Tizard is chairman of this Committee also, and three other members of the Advisory Council are also serving on it. Two of the panels under this Committee are continuing the earlier investigations into the potentialities of operational and sociological research, and a statement has recently been issued from the Economic Information Unit of the Treasury on the work of the Panel on Human Factors, of which Sir George Schuster is chairman. The Panel was constituted "to advise the Committee concerning the directions in which productivity could be increased by the application of research into the human factors in industry and to make recommendations for further researches into this field where called for". At its first meeting on February 2, 1948, the Panel decided to establish a research advisory group of representatives of the Medical Research Council, independent institutions engaged in research in the social sciences and departments of applied psychology in certain universities to advise the Panel on matters of research and on the availability of research workers.

The Panel was impressed at an early stage by the lack of workers with practical experience in the field of the social sciences, and has considered the means by which the number of workers could be increased and their training undertaken. In the meantime, it was decided to arrange for existing research institutions to undertake a series of investigations selected so as to cover points where it is important to acquire more scientific knowledge and so as to provide opportunities to train additional field-workers. The statement lists a number of projects which have thu been inaugurated, and the responsibility for supervising their completion and for making grants towards their costs has been undertaken by the Medica Research Council. In addition to these projects, certain activities of the British Institute of Managemen have been co-ordinated with the programme of th Panel, and a number of further projects from university departments are being considered.

The projects approved include studies of productivity in the Royal Ordnance Factories by the Industrial Health Research Board, and of work, desig and the measurement of human performance by th Cambridge Applied Psychology Unit. The Tavistoc Institute of Human Relations is investigating withi an engineering firm the effect of different metho of payment, joint consultation procedures, metho of communication within the firm and inter-manag ment relations, and is also examining methods disseminating knowledge by group discussion, film radio, etc. The Nuffield Research Unit, Cambridg has undertaken an investigation of the effects of ageing on productivity.

Since this statement was issued, some further information has been given by the National Institute of Industrial Psychology regarding the three research projects it is undertaking for the Panel. The first of these, on problems associated with the selection and training of foremen, includes a survey of present practice and of the status of foremen relative to the middle and higher levels of management. It is hoped that the survey will show how far recent advances are being utilized in industry, and that it will also provide material for a comprehensive job study on which to base further improvements in technique. Later it is proposed to carry out experiments to evaluate methods of selection and training under controlled conditions.

The second project is a study of methods of joint consultation in industry generally; by a survey of existing practice the Institute hopes to ascertain how many firms use consultative machinery and how effective it seems to management and men. Further work is planned to compare the effectiveness of various methods of consultation. A third study, of the effect on production of the size of unit of work, is intended to determine how far increase of job-breakdown reduces the will to work and how output varies with the size of batch handled in repetitive work.

Having inaugurated these projects, the Panel has turned its attention to more direct methods for improving industrial productivity by the wider adoption of techniques in the field of management and human relations which have already proved valuable. The projects already launched, however, besides providing for the study of a number of key factors affecting production, should serve as an experiment in a co-ordinated programme of allied research to be undertaken by a number of different organisations, and should build up a coherent body of research workers and thus increase the available strength for expanding field investigations. It is also hoped that interim conclusions may be drawn from the studies and applied as the work proceeds, even if the completion of the projects takes some time.

The Panel has clearly made a good start on the foundations laid by the Committee on Research and Productivity of the Advisory Council on Scientific Policy. Much remains to be done, for example, on the administrative side, where the responsibility of the Medical Research Council can scarcely be regarded as more than a temporary expedient while some satisfactory permanent scheme for financing and watching over the research projects for the Panel is elaborated. Nevertheless, a start has been made towards meeting the need for team work in this field on which *Planning* laid such stress in its recent broadsheet on the human factor (see *Nature*, **161**, 780; 1948), and it is interesting to note how largely the projects already initiated cover the suggestions made there.

Success in this field, as *Planning* rightly stresses, is essentially a matter of team-work, in which the leader of each team must have at his disposal a wider variety of scientific techniques and disciplines than can be compassed by even two or three workers. The central discipline involved is probably psychology, or one of a closely related group including psychiatry and industrial medicine. Experience in and some understanding of management or administration, as well as knowledge of the technical side of the industry under observation, are also important, as well as a high grade of understanding of such social sciences as economics and social anthropology. Inevitably, too, work of this kind demands ability in collecting and analysing statistics.

The second main point made in this broadsheet is that research should be done on the spot in industry, and it is clear that Sir George Schuster and his colleagues are already proceeding on such lines so far as the limited number of qualified workers permits, and that they are seeking to expand as swiftly as possible the number of trained workers necessary for such field-work on any considerable scale. We may be equally confident that the researches they are fostering will have regard to the third main point made by *Planning*, that the research should treat the industrial unit under observation as a functional whole, studying particular factors not in isolation but as elements in a total situation. The greater co-ordination between the research bodies themselves—including firms undertaking investigations on their own behalf—which the work of the Panel will promote will lead to improved methods both in the collection of data and in analysis, and it may be confidently expected that better arrangements will be made in the future than at present exist for the pooling of information as well as for the correlation of data.

Following the lead of the Advisory Council, Sir George Schuster and his colleagues have got to work swiftly on sound lines. The progress of their work will be followed with keen interest, as discussions at the recent meetings of both the British Medical Association and the British Association testify. There is growing appreciation that the informal social group lies at the bottom of any informal organisation and is the basis on which a good administrative structure must be built. The work of the Panel on Human Factors and indeed all the work of the Committee on Industrial Productivity can be counted upon to make even more widely known such results as those of the Hawthorne experiment, and to assist in overcoming the resistance of employers and of trade unions alike to the whole principle of scientific study and to the application of its conclusions.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, October 18

BRITISH MUSEUM (at the Natural History Museum, Cromwell Road, London, S.W.7), at 2.30 p.m.—Dr. J. Ramsbottom: "Edible Fungi".* (Further Lectures on Friday, October 22, Monday, October 25, and Friday, October 29.)

UNIVERSITY COLLEGE, LONDON, DEPARTMENT OF BIOCHEMISTRY (in the Physiology Theatre, Gower Street, London, W.C.1), at 4.45 p.m.—Dr. E. M. Crook: "The Electron Microscope and its Biological Applications".* (Further Lectures will be given on October 25 and November 8.)

SOCIETY OF CHEMICAL INDUSTRY, CHEMICAL ENGINEERING GROUP (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. R. S. Morse: "Recent Developments in High Vacuum Technology".

ROYAL INSTITUTE OF CHEMISTRY (joint meeting with the INSTITUTE OF SEWAGE PURIFICATION, at the County Technical College, Essex Road, Dartford), at 6.30 p.m.—Mr. A. E. J. Pettett: "Effect of Cyanides on Treatment of Sewage in Percolating Filters".

Tuesday, October 19

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (in the Chemistry Department, Royal College of Science, Imperial Institute Road, London, S.W.7), at 2.30 p.m.—Mr. J. T. Edwards: "Chemical Control of Protozoan Parasites".

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "What should be the Design Considerations of Services' Radio Equipment ?" (to be opened by Mr. S. J. Moss and Mr. G. C. F. Whittaker).

Chemical Society, Southampton Branch (joint meeting with the Portsmouth and District Chemical Society, in the Municipal College, Portsmouth), at 7 p.m.—Dr. F. P. Bowden, F.R.S. : "Tribochemistry and the Initiation of Explosives".

Wednesday, October 20

Institution of Electrical Engineers, Supply Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. C. O. Boyse : Inaugural Address as Chairman.

Royal Institute of Chemistry (joint meeting with the London Section of the Society of Chemical Industry, at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 6.30 p.m.—Dr. J. G. Fife : "Protection of Chemical Inventions".

Royal Statistical Society, North-Eastern Group of the Industrial Applications Section (at the Chemical Industries Club, 18 Lovain Place, Newcastle-upon-Tyne), at 6.30 p.m.—Dr. B. P. Dudding : "A Statistical Contribution to Production Economy".

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion on "Science and Peace" (to be opened by Prof. J. D. Bernal, F.R.S., and Prof. N. F. Mott, F.R.S.).

Irish Chemical Association (in the Department of Chemistry, Trinity College, Dublin), at 7.45 p.m.—Prof. T. S. Wheeler : "The Training of a Chemist" (Presidential Address).

Thursday, October 21

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. A. M. Bensusan : "Notes on a Small Working in Southern Rhodesia" ; Messrs. E. J. Pryor and K.-B. Liou : "A Simple Flotation Cell".

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6 p.m.—Annual General Meeting ; Mr. L. H. Bedford : Presidential Address.

Chemical Society, Hull Branch (joint meeting with the Local Section of the Oil and Colour Chemists' Association and the University College Scientific Society, in the Science Lecture Theatre, University College, Hull), at 6 p.m.—Dr. A. E. Alexander : "Surface Chemistry—its Achievements and its Future".

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. G. W. Wilson and Squadron-Leader E. P. Bridgland : "Cold Weather Operation of Aircraft".

Textile Institute (at 16 St. Mary's Parsonage, Manchester), at 7.15 p.m.—Mr. H. W. Best-Gordon : "Chemical Aids to Textile Processing and Finishing".

Textile Institute, Yorkshire Section (at the University, Leeds), at 7.15 p.m.—Mr. E. V. Giles : "Application of Plastics to the Textile Industry".

Chemical Society, Edinburgh Branch (joint meeting with the Local Sections of the Royal Institute of Chemistry and the Society of Chemical Industry, at the North British Station Hotel, Edinburgh), at 7.30 p.m.—Prof. J. W. Cook, F.R.S. : "Some Aspects of the Chemistry and Biochemistry of Polycyclic Aromatic Hydrocarbons".

Friday, October 22

Chemical Society, Birmingham Branch (joint meeting with the University of Birmingham Chemical Society, in the Main Lecture Theatre, Chemistry Department, The University, Edgbaston, Birmingham), at 4.30 p.m.—Sir Cyril Hinshelwood, F.R.S. : "Cell Growth Phenomena and Chemical Kinetics".

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Geophysical Discussion.

Manchester Statistical Society, Statistical Methods Study Group (at the Society of Architects, 16 St. Mary's Parsonage, Manchester), at 5.30 p.m.—Mr. W. A. B. Hopkin : "Some Problems of Population Statistics".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Capt. (E.) W. Gregson : Presidential Address.

Institute of Physics, Manchester and District Branch (in the New Physics Theatre, The University, Manchester), at 7 p.m.—Mr. H. L. Kirke : "Studio Acoustics and Modern Methods of Measurement".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned :

Senior Lecturer in Anatomy—The Secretary of University Court, The University, Glasgow (October 23).

Graduate Assistant Chemist in the Laboratory, Rookery Park, Erdington, Birmingham, to carry out work concerned with sewage purification—The Clerk to the Birmingham Tame and Rea District Drainage Board, 117 Colmore Row, Birmingham 3 (October 23).

Senior Lecturer in Soils and Fertilizers at the Canterbury Agricultural College, Lincoln, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (October 25).

Principal of the Shropshire Farm Institute—The Secretary for Education, Education Office, County Buildings, Princess Street, Shrewsbury (October 30).

Lecturer or an Assistant Lecturer in Structural Engineering—The Registrar, College of Technology, Manchester 1 (November 1).

Analysts for the analysis of samples of drugs and medicines taken on test prescriptions dispensed by pharmacists and authorized sellers of poisons under Part IV of the National Health Service Act 1946—The Chief Pharmacist, Ministry of Health, Whitehall, London, S.W.1 (November 1).

Chairs of Mining, Mechanical, Electrical, and Civil Engineering, in the New South Wales Technical University—The Agent General for New South Wales, 56 Strand, London, W.C.2 (November 1).

Foundation Chair of Chemical Engineering in the New South Wales Institute of Technology (Technical University)—The Agent-General for New South Wales, 56 Strand, London, W.C.2 (November 1).

Poultry Officers (2, male) in the Department of Agriculture and Lands—The Secretary, Government of Southern Rhodesia, Rhodesia House, 429 Strand, London, W.C.2 (November 3).

Senior Scientific Officer in the Ministry of Supply at the Atomic Energy Research Establishment, Harwell—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2298 (November 4).

Experimental Officers in the Chemical Inspectorate (Atomic Energy), Ministry of Supply—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2297 (November 4).

Lecturer in Anatomy—The Registrar, King's College, Strand, London, W.C.2 (November 8).

Senior Assistant in Physics—The Secretary, South-East London Technical College, Lewisham Way, London, S.E.4 (November 13).

Lecturer in Biology at the New England University (University of Sydney), Armidale, N.S.W.—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (November 15).

Lecturer in the Department of Geography of the Natal University College, Pietermaritzburg—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (November 30).

Lecturer in Botany (plant physiology)—The Registrar, University College, Southampton (November 30).

Lecturer in Chemistry in the University of Adelaide—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (December 1).

Lecturer in Economic Statistics in the Faculty of Economics of the University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (Sydney, December 31).

Senior Leturer in Botany at Rhodes University College, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (December 31).

Plant Pathologist in the West African Cocoa Research Institute, Gold Coast, to undertake investigation into the diseases of cocoa—The Director of Recruitment, Colonial Service, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Lecturer in Chemistry—The Registrar, College of Technology and Commerce, The Newarke, Leicester.

Head of the Science Department—The Headmaster, Clifton College, Bristol 8.

Honours Graduate for training as a Fish Processing Expert—The Under-Secretary of State, Colonial Office (Research Department), Sanctuary Buildings, Great Smith Street, London, S.W.1.

Lecturer in the Mathematics Department—The Principal, Northampton Polytechnic, St. John Street, London, E.C.1.

Research Bursary in the Chemistry Department of the Imperial College of Science and Technology, for fundamental research on the physical chemistry of high-temperature reactions involving iron—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

Laboratory Steward in the Department of Biology—The Principal, Technical College, Brighton.

Laboratory Assistant (man) for biology, chemistry and physics laboratories, at George Green's School, East India Dock Road, Poplar, London, E.14—The Education Officer (Estab. 2), County Hall, Westminster Bridge, London, S.E.1.

Junior Student Laboratory Technician (Grade C) in the Department of Morbid Anatomy—The House Governor, St. Mary's Hospital, London, W.2.

Laboratory Technician (Grade III) in the Department of Pharmacology—The Secretary, University College, Gower Street, London, W.C.1, quoting "Pharma/1".

Laboratory Assistant to take charge of the work in either the physics or chemistry laboratories—The Bursar, The College, Cheltenham.

Chemist by the East African Industrial Management Board, Nairobi—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N.21789/3E.

Technician in the Mozelle Sassoon Super Voltage X-Ray Therapy Department—The Clerk to the Governors, St. Bartholomew's Hospital, West Smithfield, London, E.C.1, endorsed 'Technician'.

NATIONAL PARKS IN BRITAIN

THE implications of the revolution in the British system of land tenure which occurred on July 1, 1948, when the Town and Country Planning Act, 1947, came into force, are even yet far from being generally appreciated, although the Act immediately affects millions of property owners. It represents, indeed, a great experiment in social control. Old individual liberties are put in trust for the common good; but few as yet understand the methods of community planning or the discipline which planning requires of them. Nor are the technical implications fully realized—the need for development planners of higher quality and better training, for a new tradition in which economics, sociology and geography are blended with the skill of the architect, the engineer and the surveyor into something at least approaching a science.

The success of the Act depends at all points on the readiness of local authorities to use in the public interest the opportunities it offers them. No longer need the fear of cost to themselves inhibit the use of their powers to prevent bad development. Only experience and the growth of the science of planning can ensure that those powers are used positively and constructively, not merely to prevent bad but also to encourage the best development. Moreover, there is real reason to fear that the Act does not put power in the hands of those best qualified to exercise it from a regional or national point of view. It seems that regional advisory committees are unlikely to maintain even their former persuasive influence, and that there is no intention of creating executive joint planning boards. Until the structure of local government has been organised on even bolder lines than those suggested by the Boundary Commission, the machinery for planning will scarcely match the power at its disposal.

There are two main reasons for uneasiness. The Minister of Town and Country Planning, Mr. Silkin, has always been reluctant to admit that there might be needs which the Act does not meet, and in a recent speech at Cambridge he misrepresented seriously the views of the national park movement in seeking to defend his resolve to reject even the compromise for a national park authority represented by the recommendation of the Hobhouse Report. While he refrained from making suitable provision for national park planning until it automatically became vested in the county councils, he now protests that it would be unreasonable to take away from them what they have so recently acquired.

It has long been plain that the county councils do not accept the essence of the national park thesis: Great Britain is a crowded island; but a few areas must be reserved in which the claims of natural beauty and its enjoyment shall stand supreme. The Southampton Borough Council's proposal to invade a public park in Southampton, against which hundreds of objections have been lodged, is only one recent example which demolishes Mr. Silkin's contention. Such examples could be multiplied indefinitely in London, Manchester and many other places, where although some encroachments might be justified, most are due to the authorities taking the line of least resistance. The natural beauty of Britain cannot long survive such a process of attrition, and a great merit of the pamphlet "National Parks or 'Local Authority' Parks", just issued by the Friends of the Lake District, is that it displays clearly the picture of attrition in one particular area over the last twenty years. On any wide and general view, the Lake District has lost not a little which it can never regain, and has not had the treatment proper to a kind of national property. During the last generation, the best areas of our landscape have suffered steady attrition, and both the pace and the field of injury are increasing.

Even if the local authorities could be expected and trusted to take a national view, it is also clear that, as 'local' authorities, they would be unable to avert the second main danger—that of encroachment from the Departments of State, and especially the Service Departments. Strong opposition has been manifest to the Army's proposed requisition of 1,870 acres of Cannock Chase; opposition which was supported indeed by the Staffordshire County Council. Already the Armed Forces have demanded a gun site near Holy Island, a bombing range at Selsey Bill and battle-training areas across Norfolk and Wiltshire villages, and cynically disregard promises or pledges given during the War. Retention of the areas held at Stamford and at Purbeck for battle-training areas is leading to widespread distrust of the Government's sincerity or even good faith.

Nor is it only the Service Departments that are responsible. Water supply and catchment area authorities, the Ministry of Transport, and the Forestry Commission all sponsor demands which despoil the countryside, and often encroach on areas recommended for preservation as national parks or Nature reserves. Seldom is there any indication of an attempt to consider alternative means of meeting a sectional or local need without detriment to the interests of the nation as a whole. The report of the Gathering Grounds Sub-Committee of the Central Advisory Water Committee on "Public Access to Gathering Grounds and Afforestation and Agriculture on Gathering Grounds" (London: H.M. Stationery Office, 1948. 9*d.* net) constitutes an honourable exception, which deserves special mention. Under the chairmanship of Mr. A. P. Heneage, this committee has brought an admirable sense of national interest to bear on a special problem, and declined to allow unsupported sectional prejudice to prevail. Its recommendations relate to the conduct of the gathering grounds of upland reservoirs where adequate purification processes exist. Arrangements should be made, it urges, to dispose of the sewerage from human habitations, whether permanent or temporary, in a manner that will entirely preclude the possibility of its getting into the reservoirs. Farmyard manure should be prevented from draining directly into feeder streams or reaching the reservoir, and the public should be generally excluded from the banks of reservoirs and no bathing allowed. Fishing and boating may sometimes be allowed at the discretion of the authority, but only under rigorous control. Feeder streams may sometimes require like restrictions; but subject to these safeguards, the land should be put to the utmost agricultural use, and land which is incapable of agricultural use should, if possible, be afforested, but with due regard to amenity and the requirements of adjacent agriculture. Subject to these recommendations, the committee sees no reason for excluding the public from gathering grounds as such. Indeed, the report is a well-deserved rebuke to certain authorities which have relied on such negative restriction rather than on the positive safeguards which are still required even if the public are excluded. Incidentally, the committee was satisfied that many gathering grounds could be put to much greater agricultural production than at present.

Despite the admirable spirit of this report, there can be little optimism at present that due effect will be given to its recommendations in the absence of adequate authority. Provision of the essential requirements for a system of national parks and for co-ordinating at the highest level the competing departmental requirements for land would, of course, meet this requirement incidentally; but even the requirements urged by the Friends of the Lake District will scarcely avail while the Government refuses to establish a more effective authority than an inter-departmental committee, and continues to allow demands for land to be presented piecemeal and without regard either to available resources or competitive national needs.

Whether or not it was the intention that the Minister of Town and Country Planning should act as the co-ordinator in this matter, events have demonstrated that he possesses neither the stature nor the vision to exercise such authority. Meanwhile, it is clear, in view of the probability that the Government's programme for the forthcoming session will include a Bill to secure freer public access to mountains and moorland, to control holiday facilities in national park areas and to conserve wild life, that the essential requirements for an effective system of control should be understood.

The two essential principles outlined by the Friends of the Lake District and in the earlier reports are essentially the same both for national parks and Nature reserves, differing only in the details of application for the two purposes. The first requirement is to concentrate in a specialized body, a national parks commission, the duty of elaborating and maintaining a special code for the parks and Nature reserves. This would provide the means for dealing directly and on more or less equal terms with Government departments and public corporations, and it would also avoid the anomalies which will arise if the control is left with the county councils, as Mr. Silkin suggests, a scheme under which the Lake District would be administered by three, North Wales by four, and the Peak district by four or five separate bodies.

Secondly, on the plane of local planning, the national interest must be introduced by establishing a special park or Nature reserve committee. This would provide a unified planning authority for dealing with each park as a single whole, assessing the national need against local needs. Mr. Silkin himself and other participants in the recent controversy have misrepresented this function, in spite of overwhelming evidence that the local authorities cannot be relied upon to put national interests first, and indeed should not in fairness be expected to do so. In answering that criticism, moreover, the Friends of the Lake District in the pamphlet referred to also dispose of the suggestion that the parks committees, constituted as suggested in the Hobhouse Report, are undemocratic; and they quote pertinent instances in regard to roads, electricity and the National Assistance Board in support of the reasonableness of the Hobhouse compromise. Nor can it well be argued that from the purely administrative point of view the proposed system for national parks cannot be worked side by side with that laid down for other purposes in the Town and Country Planning Act of 1947.

What must be clearly understood at the present moment is that at no level is the necessary administrative machinery established or retained under the new Planning Act to enable a consistent planning policy to be applied either to national parks in general or throughout any one of the principal national park areas designated in the National Parks Committee's reports, or those of the Wild Life Conservation Committee. Even if the local authorities were really interested in national parks and there were not the difficulty of particular parks being the concern of three, four, or five county authorities with widely varying outlooks, populations and rateable values, the administration of such areas puts an unreasonable strain on the loyalties of the councils. County parks they might provide, but not national parks; and there would be no assurance that these parks would be secure against the intrusion of sectional interests, let alone of Departments of State.

It cannot be too strongly emphasized that in little more than a year after the publication of the Hobhouse Report, not only has no action been taken to implement its proposals, but also in the interval further irreparable damage has been done to our dwindling reserves of natural beauty, amenity, flora and fauna; urther, that the conception and prospect of both national parks and Nature reserves have become more seriously endangered than at any time since Mr. John Dower was asked to prepare his report, nd that by Government action—and inaction. It equally true that the new Planning Act, the Requisitioned Land and War Works Act and the White Paper on the Needs of the Armed Forces for Land for Training and Other Purposes, have done more on the whole to alarm than to reassure public opinion, and have to some extent tended to dissipate that considerable measure of goodwill on which the rospects of a general agreement and an effective afeguarding of Britain's heritage of natural beauty nd wild life must be based. In this respect the Government seems to be bent on evading the responsibilities conferred on it, with widespread pproval, by recent legislation.

RADAR, BEACONS AND NAVIGATION BY RADIO

(1) Radar Aids to Navigation

Edited by Assoc. Prof. John S. Hall. (Massachusetts Institute of Technology, Radiation Laboratory Series, Vol. 2.) Pp. xiii+389. (New York and London: McGraw-Hill Book Co., Inc., 1947.) 30*s*.

(2) Radar Beacons

Edited by Prof. Arthur Roberts. (Massachusetts Institute of Technology: Radiation Laboratory Series, Vol. 3.) Pp. xx+489. (New York and London: McGraw-Hill Book Co., Inc., 1947.) 36*s*.

(3) LORAN: Long Range Navigation

Edited by J. A. Pierce, A. A. McKenzie and R. H. Woodward. (Massachusetts Institute of Technology: Radiation Laboratory Series, Vol. 4.) Pp. xiv + 476. (New York and London: McGraw-Hill Book Co., Inc., 1948.) 36*s*.

ALL those who have been in any way connected with the vast developments in radio and radar techniques during the past decade will be familiar with the extensive contributions made during the war years by the staff of the Radiation Laboratory of the Massachusetts Institute of Technology. Much of the basic scientific and engineering knowledge which resulted from these contributions has been collected together by an editorial staff working under the auspices of the United States National Defense Research Committee and is now being published in a series of volumes which has become familiarly known in the radio world as the 'five-foot shelf'. The general design and scope of this publication, and details of the introductory volume to the series, have already been described in *Nature* (June 5, p. 867). The present review is concerned with Vols. 2, 3 and 4 of the series, which together add another three inches to the shelf.

(1). As its name implies, the volume edited by Dr. John S. Hall describes the advantages and limitations of radar technique when applied to the problems of navigation and pilotage, whether the equipment is airborne, shipborne or ground-based. The book is divided into four parts, the first of which is of an introductory nature. An opening chapter on the principles of radar serves to make the book self-contained without reference to the first volume of the series. The second chapter has also been included to give the reader a more comprehensive picture of available techniques, and deals with what are termed non-radar navigational aids. These include various techniques for determining the direction of a sending station, and also the hyperbolic systems that measure range differences such as Decca, Gee and Loran: the latter is dealt with in considerable detail in volume 4 of this series (see below).

The real substance of the present volume begins in Part 2, entitled "Airborne Radar". The four chapters in this section are devoted almost exclusively to the characteristics, design and performance of the type of centimetre-wave radar equipment developed for precision blind-bombing purposes during the War, and now being applied to the navigation of civil aircraft. A series of excellent photographs illustrates the detailed display that can be obtained in this technique with systems of high resolving power used on a wave-length of 1·25 cm. Unfortunately, it has been found in practice that the presence of a water-vapour absorption band precludes the use of this wave-length except in very clear air and at short ranges; and with the longer wave of 3 cm. now being generally adopted, the features presented to the operator or pilot are less distinct, although they still retain considerable navigational value.

Part 3 deals with centimetre-wave radar equipment used on the ground, particularly for the guidance and control of aircraft traffic at and between airports. In this case the restriction on the size of the antenna system which may be used is not so severe as with mobile equipment, and high resolution can be obtained with the longer waves, up to 10 cm., which have been used so successfully for aerodrome approach and landing purposes. Chapter 8 is devoted to the important subject of air navigation and traffic control, which will present problems of increasing importance, particularly in bad weather conditions, as the use of civil aircraft grows in the next decade or so in all parts of the world.

The last two chapters in the book comprise its fourth part, entitled "Shipborne Radar". Much of the material here presented will be more familiar to those who have followed the recent application in Great Britain of centimetre-wave radar to mercantile marine navigation. But it is interesting to have this description of the earlier work done in the United States, upon which are based the corresponding developments there.

Altogether the preparation of this volume by the thirty-three authors responsible for it has been well worth while; but it is perhaps a pity that it was decided not to include a glossary, which would have made things a little easier for the reader who is not very familiar with radar technique and language.

(2) The next volume, by Prof. Arthur Roberts, can be regarded as in a sense complementary to the one referred to above. For a radar beacon is a device which is normally quiescent but which, when 'interrogated' by a suitable pulse-modulated signal from a radar sender, 'responds' by emitting another signal much stronger than that which would have been obtained by reflexion as in simple radar. It is learnt in the first chapter that the radar beacon was invented in 1939 by a group of British workers at the Bawdsey Research Station of the Air Ministry, in response to a need for distinguishing between enemy and friendly aircraft when using radar detection methods. From this simple beginning, the radar beacon was developed during the War for a variety of applications, of a navigational, offensive and defensive nature. This book describes the work on beacons which was carried out in the Radiation Laboratory, where a separate division was organised for the purpose in 1943.

For the general reader the first part of the book, entitled "Basic Considerations", is probably the most interesting. In the course of six chapters, prepared chiefly by the editor, a most useful account is given of the technical possibilities of beacons for ship, aircraft or ground-station use. The methods of interrogation and reply coding to discover, and identify beacons, the synchronization of signals for the determination of their range, and the effects of propagation conditions, choice of frequency and interfering signals are all described in a lucid manner. The sixth chapter deals with traffic and engineering considerations, and discusses such matters as the saturation of the interrogation link and the permissible density of beacons; subjects which are likely to be of great importance in the application of beacon technique to civil air navigation.

Part 2, which comprises about half the book, describes in some detail the component parts of a beacon and their assembly into the complete equipment. The experience and technical progress here recorded should prove invaluable to the engineer responsible for designing a radar beacon system for any purpose. In a similar manner, Part 3 supplies the corresponding information required for the design and development of the radar interrogation system with which the beacons are to co-operate in providing the desired information as to range and azimuth. Typical beacon systems for air-to-ground and ship-to-shore use are described in this part of the book; and brief reference is made to the Shoran precision beacon system, which, although not developed at Massachusetts, is referred to as the most accurate radar system for aircraft navigation to horizon ranges that had been developed up to 1945. In this method the navigator in the aircraft determines his position accurately by measuring range only to each of two fixed beacons at known locations on the ground.

The final chapter, comprising Part 4 of the book, gives a useful account of experience in the choice of sites for beacons on the ground and in ships and aircraft, and in the installation, operation and maintenance of beacons in such situations. In view of the large number of special terms and code letters which have arisen during the development of radar-beacon technique, the glossary given at the end of the book will be particularly welcomed by the student and reader who are not too familiar with this subject.

(3) The fourth volume of the Radiation Laboratory Series describes a long-range system of navigation, which depends upon the transmission and reception of pulse-modulated radio signals, but which differs from radar technique in using much longer waves and in not involving reflexion from a target. The Loran system, developed at the Radiation Laboratory during the War, is a hyperbolic navigational aid in which the position of a receiver is determined by the simultaneous observation of distances from two pulsed sending stations in known positions on shore It has many points in common with the Gee system developed somewhat earlier in Great Britain for the navigation of aircraft out to horizon range and somewhat beyond; but by the use of much greate wave-lengths, or lower frequencies, Loran provided a means whereby ships, as well as aircraft, could be navigated to distances of from 500 to 1,500 mile using both ground and ionosphere-reflected waves The progress made in the exploitation of the Loran system in America was very rapid, and at the end o the War some seventy transmitting stations were in operation in various parts of the world, and detail of these are given in an appendix to the book.

The purposes of the present volume are to describe first, the principles of the Loran and its possibilitie as a means of navigation over considerable distances and secondly, to record in some detail the positio which the development of the necessary equipmen had reached at the close of hostilities. After a introduction and a brief account of the history o the subject, the third chapter describes the principle of Loran, based on the measurement of the relativ times of arrival of received pulses emitted alternately with a known delay interval, from two fixed sendin stations. Both stations are equipped with cryst oscillators which define the pulse recurrence-rate, bu one of the pair acts as the master and is used t regulate the oscillator of the second or slave station. Assuming a knowledge of the speed of the radio waves and of the paths along which they travel from sending to receiving stations, then the relative distances of the two fixed stations can be determined to a very high accuracy from the time observations made at the receiver. The carrier frequencies chiefly used in the practical development of the system were about 2 Mc./s. for the standard Loran and 180 kc./s. for low-frequency Loran. In Chapter 5, the propagation of waves at these frequencies is discussed, first with the view of demonstrating that for ground-wave transmission the maximum useful range is about 700 miles at the higher of the above frequencies and about twice this distance at the lower frequency. Consideration is then given to the propagation of these radio waves through the ionosphere and the consequent effect of diurnal and other variations on the received observations. Much empirical information has been collected together in this chapter, and this will probably repay further study in connexion with the future application of this system of navigation. Chapter 6 deals with methods of computing the tables and charts which form such an essential part of a practical system of navigation, where the operation of converting the radio observation into a charted position must be accomplished as quickly and as simply as possible. It is stated in the preface that, up to the end of the War, the U.S. Hydrographic Office had prepared and issued two and a quarter million of the special hyperbolic charts required by the agencies operating the various chains of Loran stations.

The second half of the book, comprising the last six chapters, deals in some detail with the various items of equipment and technique forming the complete system. These chapters, like the remainder of the book, are profusely illustrated with diagrams and photographs, and give clear descriptions of the transmitting and receiving equipment, the antenna systems, and particularly of the special techniques and apparatus used for regulating and timing the pulse-modulated waves. Appendixes devote further space to discussion of the geometry of the Loran system and to the determination of errors in the positions of the transmitting stations. A classified bibliography occupying twelve pages is given at the end of the book: a very small proportion of the references are to normal technical publications, the great majority being to the special reports and instruction manuals which were produced during the war years by those responsible for the development of the various phases of this new and successful means of long-range navigation.

Altogether, these three volumes form a noteworthy and most welcome addition to radio literature and will ensure that much of the specialized knowledge and experience gained at the Massachusetts Institute of Technology during the war years is readily available to future workers in this subject. The preface to two of the books and of others in the same series concludes with this sentence: "The publishers have agreed that ten years after the date on which each volume of this series is issued, the copyright thereon shall be relinquished, and the work shall become part of the public domain". Sixty-five contributors to these three volumes have achieved, in the words of a previous reviewer, "a brilliant and amazingly successful piece of co-operative authorship", and the radio, scientific and engineering world is indebted to them for their efforts. R. L. SMITH-ROSE

POPULATION POLICY IN GREAT BRITAIN

Population Policy in Great Britain

A Report by P.E.P. Pp. viii + 228. (London: Political and Economic Planning, 1948.) 15s. net.

ARE the British people able and willing to maintain their numbers, and is it desirable that they should? If, as anticipated, the reply is affirmative, how can we ensure that our children shall be naturally well endowed and properly equipped as members of society to face the difficult years ahead? P.E.P., in answer to these basic questions, assumes that British society will remain democratic in its devotion to individual freedom and that the principles and practice of a future population policy—unfortunately, not yet even dimly discernible!—will be in harmony with our traditions.

In the decade that preceded the Second World War, British opinion was roused by contemporary prophets to the dangers of depopulation, then forecast as ultimately certain if not imminent. In these immediate post-war years, however, the prediction has been at least temporarily disturbed by a buoyant birth-rate, notably that of 1947, which was higher than for any previous year for a quarter of a century. The report depends on the assumption—to P.E.P. the only prudent one in the light of all the available evidence over a prolonged period—that, notwithstanding temporary spurts of fertility, the total number of people in Great Britain by 1970 will have become stationary or will be on the decline. (In such predictions the non-intervention of unforeseen, cataclysmic events is, of course, assumed.) The report, in eloquent appreciation of the danger to the nation and patriotically inspired, hopes to stimulate Britain to a reversal of the expected calamitous decline in both numbers and national vigour.

In the light of racial and cultural affinities, it comes, with no surprise to learn that population trends in Britain closely resemble those of our nearest continental neighbours. Britain's problem is that of all Western Europe, as nowadays the region is politically and ideologically conceived, and our international colleagues seem no more prepared than we are to meet the challenge of a falling birth-rate. The position in Eastern, Slavonic, Europe is notably different and likely within relatively few years to alter the balance of man-power in the Old World. From the Office of Population Research of Princeton University comes the estimate that, whereas in 1940 in Europe (without the U.S.S.R.) the percentage of total man-power made up of men of fifteen to thirty-four years was little more than 50, in the Soviet Union it was 61; and the forecast that in 1970 the advantage of the great eastern Power will be even more. As the report under notice tersely remarks, the political and economic implications of these estimates require no emphasis.

For Western Europe alone, the report fails to underline the important differences in geographical fortune between the various countries: it deserves emphasis that Britain, apart from Belgium, is easily the most densely populated of the occidental Powers, its economic and social prosperity more vulnerable than that of any to the threat from an ageing population. The assumption that Britain is not overcrowded, but rather the victim of a geographically unbalanced distribution of its inhabitants which can and will be corrected, would seem to be too readily accepted; as also the likelihood of our being able to disperse the almost unparalleled congestion of our towns, preserving at the same time both the agricultural soils—our richest material possession—and the scenically attractive zones of Britain on which the physical and mental health of the nation increasingly depends. The suggested alternative to the establishment of new urban centres at Crawley, Stevenage, etc., of their transference to the under-populated Dominions, shows the authors to be aware of the possible danger which some observers consider inevitable in the present official policy of 'new towns for old'.

There is much valuable discussion of an 'optimum' population, without, however, an approximation to the most advantageous total for the British Isles. That it should be larger than the present and continue to expand—with an average of 2·5 children per family—is regarded as axiomatic; indeed, on that basis the entire argument and consequent proposals rest. Yet there is neither criticism nor discussion of the recent assertion of an official Australian spokesman (here quoted) that "the best population for Britain would be 30 millions". There is commendable insistence, however, that the attainment of a numerical target is not so vital as the removal of existing obstacles to parenthood and an improvement in the quality of the population.

In these critical years the youth of Britain, whose welfare is the *sine qua non* of the nation's vigorous survival, seems likely to be tempted away on a scale of emigration unknown since the trans-Atlantic migrations of the late years of the nineteenth century. Largely in consequence of the two World Wars, the new countries which exert a powerful 'pull' on British youth have passed from being debtor to being creditor nations, able to provide capital for the opening-up of their undeveloped territories and for large-scale settlement. But Britain, after two generations of declining fertility, can no longer be complacent at the prospect of losing by emigration the youngest and most enterprising of its citizens. The Dominions should be prepared for the proposal that large-scale migration from our shores should represent a cross-section of the British population, both by age and occupation. How this could be effected without recourse to compulsion would inevitably be one of the more urgent topics for the consideration of the research institute for Commonwealth population questions, the establishment of which is one of the many wise proposals of the report.

Although the mortality-rate and the expectation of life in Britain leave scope for improvement—as New Zealand's superior figures under both headings show—they are satisfactory when compared with those of the great majority of Western nations, and it is not in these directions that anxiety exists. Both popular impression and investigation of the causes of the decline in the natural increase of our population leave no doubt that easily the most potent of these causes is the voluntary limitation of families by parents whose motives, however accurately guessed, cannot be certainly known without the thorough investigation now demanded. It is certain, however, that the practice of family limitation has spread from the class of highest social status to the lowest, and that with it has gone a narrowing of the gap between both their respective birth-rates and their respective cultural standards.

That parenthood is increasingly a matter of choice must be positively welcomed; but only so long as it is inspired by confidence in the destiny of both the nation and the civilization it represents. Without this sense of destiny on the part of the community, the work of the social reformer inevitably meets frustration; which certainly is an aspect of the population problem requiring the most earnest attention.

WALTER FITZGERALD

HERBS AND DRUGS

Drugs from Plants

By Dr. Trevor Illtyd Williams. (Sigma Introductions to Science, 10.) Pp. 119 + 12 plates. (London: Sigma Books, Ltd., 1947.) 6*s.* net.

THE popular appetite for information about the healing virtues of plants has been abundantly catered for by books written from the angle of herbalism. It is a long and honourable tradition, and few incidents in the history of science can be better known to the layman than the original stimulus that came to the study of plants from the appreciation, however imperfect, of their value to medicine. Unfortunately, the outlook of these modern near-herbals remains medieval, and little popular attention has been directed to the large number of important vegetable drugs in the modern pharmacopœias and to the fact that their number, as witness curare and penicillin, is still increasing. There is undoubtedly room for a book that will do something towards making clear to the layman the distinction between herbs and plant drugs.

In a series of introductions to science this title is an excellent, indeed almost an inevitable, choice; and the main problem confronting the author has been that of selection from the riches offering themselves. Plant drugs are of all degrees of significance, from morphia, without which, it has been said, few would be willing to practise medicine, to valerian, about the usefulness of which practitioners still fiercely argue. With only 119 pages at his disposal, the author has followed the sensible plan of selecting a few pre-eminent examples for discussion, and his choice has fallen upon quinine, followed by digitalis, penicillin, ergot, opium and cocaine. The last two raise the problem of drugs of addiction, and the author has added hashish (marihuana) for good measure. Other important plant drugs are briefly catalogued in a single chapter.

The author states his opinion that works of popular science should be entertaining; and it is also evident that he believes a dreadful example should live up to its name. The subject in hand lends itself so readily to sensationalism that in an account addressed to non-technical readers it is hard to know where an objective statement of fact ends and a desire to horrify begins. Suffice it to say that neither the author nor this reviewer has flinched.

On its technical side the subject straddles chemistry, botany, pharmacology and half a dozen other related arts and sciences. This is a formidable list for any publicist to tackle. His apprenticeship to chemistry has enabled the author to do what may be done towards explaining to laymen the structural chemistry of the very complex substances involved. He has not always been so happy in other branches. References to 'female flowers' have got many a botany student into trouble; *Atropa belladonna* is not a tree, and its leaves contain about a twentieth of one per cent of total alkaloids, not "½ per cent of pure hyoscyamine". Other statements calculated to cause a similar degree of discomfort to botanists occur here and there. Pharmacologists in Britain rarely use cats to standardize digitalis preparations; frogs are generally used. More important, since it involves an analytical principle, it is no longer correct to say that the unit of potency is defined as the quantity of digitalis necessary to stop the heartbeat of an anæsthetized cat or to kill a frog. It is defined as the potency of unit weight of an arbitrarily selected and carefully maintained standard preparation.

This little volume is not a technical handbook, and such inaccuracies are therefore of small account. What is valuable is its method of approach; and the layman who wishes to get a first appreciation of 'Nature's remedies' may do so here along sound lines.

W. O. James

DEVELOPMENT OF SYNTHETIC RUBBER IN THE UNITED STATES

Buna Rubber

The Birth of an Industry. By Frank A. Howard. Pp. xii + 307. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1947.) 21*s*. net.

THE author of this excellent book was, until his retirement in 1945, vice-president of the Standard Oil Co. (N.J.), of which he was principal executive for more than twenty-five years, directing and organising research, technical development and other related activities. He is probably the only man who is in a position to tell the story of the birth and development of the synthetic rubber industry in the United States, and he does so with a detachment which makes one almost forget that he was in the centre of the stage during the whole of the time and that, but for his faith and persistence, synthetic rubber might not have been produced in the United States in time to prevent a calamity.

The book falls naturally into two parts, the first dealing with the period from 1919 until 1939, and the second with the war years.

Co-operation between the Standard Oil Co. and its subsidiaries of America and the I.G. Farbenindustrie of Germany led to the formation in 1929 of a joint company, the Standard–I.G. Company, for he purpose, among other things, of enlarging co-operation in research and development on new products and processes. The final result of this co-operation brought to America the technique of he preparation of Buna *S*, an all-purpose synthetic rubber better known in Britain as *GR-S*, obtained by the copolymerization of butadiene and styrene.

The author tells how he instigated the original approach to the German company and of the liaison work which he afterwards carried out. He had realized in the early 'twenties the enormous potential value (to his country) of an all-purpose synthetic ubber, and his Company tried to interest rubber manufacturers in Buna *S*. Quite naturally, however, hey were apathetic, as there were ample supplies of he natural product, and the Government was not prepared to subsidize the necessary development work even after the start of the War in Europe. Howard tells with what sense of urgency he and his colleagues regarded the necessity for the setting up of a synthetic rubber industry and how, in the face of general apathy, his Company decided to erect the necessary plant for the manufacture of Buna *S* on a small scale.

Even after Pearl Harbour, all their efforts to get this vital material made on a large scale came to nothing time and time again, until the setting up of the Baruch Committee in August 1942; and the resulting appointment of a rubber director with absolute power cleared away all the difficulties, with the result that in a very short time the American synthetic rubber industry was among the largest in the country.

This book is so outstanding that it is unfortunate that, in Great Britain at least, the title may have the effect of limiting its readers to rubber scientists; but it is so well written and tells its thrilling story in such a clear and unprejudiced manner that it should command a much wider audience.

The printing and binding are first-rate and the only errors detected were "Briton" for "Britain" in what may be considered a controversial passage on page 110, and the spelling of the surname of Wallace H. Carothers with a 'u'. The appendix of 51 pages will be much appreciated by those readers who wish to delve more deeply into the history of Buna *S*.

C. W. Long

PROCESS HEATING IN INDUSTRY

Industrial Applications of Infrared

By James Doyle Hall. Pp. x + 201. (New York and London: McGraw-Hill Book Co., Inc., 1947.) 21*s*.

IN 1938 publicity was first given to the use of radiant heat from electric lamps for the acceleration of paint drying. Since then the technique has been developed and extended, and now radiant heating is being used in many different industrial processes. Other sources of heat have been introduced. The present book, written by a lamp engineer, is concerned primarily with the use of electric lamps; and it describes in some detail the properties and design of lamps, reflectors, conveyors and other associated equipment for a very wide range of applications. A most notable feature is the inclusion of more than a hundred illustrations of working installations.

A few pages are devoted to 'radiant cup' gas burners; but no mention is made of the radiant plate type of oven which is quite common in Great Britain; nor is there any reference to the industrial use of electric heaters with nickel–chromium elements for giving higher intensities of radiation than are possible with lamps.

Within the limitations which the author has set, the book presents the case for radiant heating in a clear, attractive and readily usable manner, and it should be of considerable help to production engineers. It does, however, suffer to some extent from its own limitations. The case for lamp heating might have been stronger if the book had included a balanced comparison with other methods of process heating which are widely used in many of the fields discussed in the book.

M. R. Gavin

The Journal of the Institute of Metals

Vol. 72, 1946. Edited by N. B. Vaughan. Pp. lvii+732+80 plates. (London: Institute of Metals, 1946.) £3.

VOLUME 72 of the *Journal of the Institute of Metals* contains 721 pages of text together with an index occupying another ten pages, and fully maintains the high standard expected from this publication. Practically every aspect of non-ferrous metallurgy coming within the scope of the Institute is represented in the twenty-six papers, together with the discussions and correspondence upon them. To the metallurgist, the engineer, and the physicist concerned with the fundamentals of the metallic state alike, there is a direct appeal. The presidential address of Col. P. G. J. Gueterbock is of more than normal interest to those concerned with the health of the metallurgical industry as a whole, and the thirty-sixth May Lecture by Prof. N. F. Mott illuminates the relationship between atomic physics and the strength of metals. Of the remaining papers, the effects of residual stresses are considered in relationship to the fatigue of aluminium alloys; and Lunt and MacLellan give a detailed mathematical treatment of the wire-drawing process. H. W. L. Phillips deals at length with the alloys of aluminium containing magnesium, silicon and iron, and has an interesting account of the application of some thermodynamic principles to the liquidus surfaces of these materials. Corrosion problems, which have always interested the Institute, are dealt with in four papers, of which one may perhaps particularly mention that of Dr. Cuthbertson on the resistance to sea-water corrosion of some α-tin bronzes. The structure of ingots and castings is the theme of three papers; ageing effects of three more, and fatigue problems crop up repeatedly. There will, in fact, be few concerned with non-ferrous metallurgy to whom some of the contributions are not of direct appeal.

Considering present-day difficulties, the editor and his staff are to be congratulated on an admirably produced volume, and on the illustrations, which, as usual, attain a very high standard.

Swelling and Shrinking

A General Discussion by the Faraday Society held at the Royal Institution on 24th, 25th and 26th September, 1946. (Transactions of the Faraday Society, Vol. 42B.) Pp. 304. (London and Edinburgh: Gurney and Jackson, 1946.) 20*s*.

THIS publication brings together the series of thirty-four papers read at the Royal Institution meeting in 1946, together with summaries of the discussion which took place and some subsequent communications. An account of the discussion appeared in *Nature* shortly after the meeting (**158**, 571; 1946), and need not be duplicated here. It is only necessary to commend this volume as a most useful reference book for all who are interested in any aspect of the physical interaction of polymers with liquids. The field covered is extremely wide, ranging from aqueous systems possessing a well-defined structure which can be studied by X-ray methods to non-polar systems in which the components show a close approximation to random mixing.

As usual in the Faraday Society discussions, the subject is covered in an extensive rather than an intensive manner. This volume will therefore be found extremely useful as a first source of information, and it serves this purpose the more admirably in view of the fact that specialists from so many different fields have contributed, thus bringing together under a single cover papers which might otherwise have been scattered through a wide diversity of journals.

Visages de la mathématique

Essai de semi-vulgarisation de quelques aspects fondamentaux de la pensée mathématique. Par Dr. Pierre Defrise. Pp. 126. (Bruxelles: J. Lebègue et Cie., n.d.) 60 francs.

MATHEMATICAL research has two aspects. The more obvious is the solution of problems which arise in the branches of the subject already known. But there is also the logical and philosophical study of the foundations of mathematics, and of the relation between its different branches. Strangely enough, it is the second aspect as well as the first which is indispensable for a full understanding of modern physical theories, such as relativity and quantum mechanics. Dr. Defrise believes that a real understanding of science is impossible without at least a general idea of this second aspect. He has therefore tried to give a treatment of non-Euclidean geometry, the 'axiomatic method', the theory of groups, invariance and transformations, in a form requiring no knowledge of mathematics beyond the ordinary school course and suitable for the non-specialist reader. But this reader must possess a logical mind and a capacity for abstract thought which are not characteristic of 'the man in the street' in Great Britain, whatever is the case in Belgium and France. However, the reading of this little book would be very profitable, if not always very easy, to teachers of elementary mathematics in Britain, as Dr. Defrise's emphasis is on that aspect of geometry which is entirely omitted from our ordinary school course. H. T. H. PIAGGIO

A Picture Book of the Whole Coast of England and Wales

An Account of Variety in Scenery and its Causes. By J. A. Steers. Pp. vii+36+148 plates. (Cambridge: At the University Press, 1948.) 10*s*. 6*d*. net.

THE first Minister of Town and Country Planning commissioned Mr. J. A. Steers to carry out a personal survey of the whole coast-line of England and Wales and to present an assessment of its varied scenery which might serve as a guide should legislation to conserve the coast from further spoliation be regarded as necessary. The results of the survey were published as a large volume, "The Coastline of England and Wales", issued by the Cambridge University Press. In order to make the unique collection of 115 photographs available to a wider public, the publishers have reproduced them, together with thirty-one others and two colour-photographs, in this attractive picture book. A map shows the position of each picture, and there are brief notes on each; while in fifteen informative pages the author has dealt with the chief types of coast and the origin of each. The photographs are remarkable in that they avoid hackneyed subjects and often present well-known views from an unusual angle. The Royal Geographical Society has permitted the reproduction of the map assessing coastal scenery, and Dr. Fraser Darling contributes an introductory essay. The result is a book which can scarcely fail to whet the reader's appetite for a taste of the larger volume.

L. D. S.

COLOUR VISION

DURING the last few years, an air of dissatisfaction has become apparent in some quarters over the adequacy of the orthodox colour vision theories to explain the facts. There has even been some dispute about the facts themselves; but there is at least agreement that since one wave-length can be distinguished from another by its colour, some mechanism of colour discrimination must exist in the retina. All the theories have something in common, in that they all assume that there must be more than one type of receptor in the retina, the types differing, *inter alia*, in their spectral sensitivity. Given these different receptor types and assuming that they can send messages to the brain which give rise to distinctive colour sensations, then we evidently have the essential ingredients for a colour discrimination mechanism. Current argument is largely concerned with the probable number of these distinctive receptors, ranging from the two anatomically distinct types as suggested by Dr. E. N. Willmer on histological grounds to seven as postulated by Prof. H. Hartridge in his polychromatic theory. Three has previously been the most popular figure—a choice stemming from colour-mixture experiments.

This question was the subject for a full-day discussion in Section I (Physiology) of the British Association during the recent meeting at Brighton. The discussion was opened by the presidential address to the Section given by Prof. H. Hartridge, in which he elaborated the arguments in favour of at least seven different receptors. He referred to a number of phenomena which he felt were inadequately explained by existing theories, among them the suppression of the colour fringes which must be formed around the image of a point source of light according to reliable data on the chromatic aberration of the eye, and also the changes in colour which occur when the angular size of a test object is reduced, particularly the change from yellow to white and blue to black. The suggestion that this was due to the blue-blindness of the central fovea could not, he said, be upheld, since similar changes were observed all over the retina; moreover, the changes could be reversed by increasing the intensity of the stimulus.

Another piece of evidence which was difficult to reconcile with the trichromatic theory was the notch in the luminosity curve in the yellow part of the spectrum, as observed by Sloan and by Wright under certain conditions of reduced field-size and reduced illumination. The explanation, as he conceived it, was the existence of a yellow receptor which, when the stimulation was reduced, became inactive and consequently left a dent in the luminosity curve. He also felt that the colour-mixture curves—the dichromatic coefficient curves—obtained by Willmer and Wright under small field conditions were so different from the normal trichromatic coefficient curves that they could not be interpreted merely in terms of the inactivity of only one receptor out of three.

One difficulty faced by any theory postulating a number of different colour receptors was the close similarity in the value of the visual acuity obtained both for white light and for various monochromatic lights. It might be expected that stimulation with monochromatic light would leave a considerable proportion of the retinal receptors either inactive or with greatly reduced activity, so that there would in effect be considerable gaps between the receptors actually functioning. This might be expected to lead to a marked loss of resolving power, and Prof. Hartridge was not prepared to accept the idea that involuntary eye movements caused the image of an acuity test object such as a Landolt ring to be scanned by the retinal mosaic, in much the same way as a television picture is scanned. He considers that the evidence on eye movements at present available does not support the idea that any such scanning takes place.

Moreover, when he studied the question of the fixation areas of the retina used for different colours, he has found from experiments with his microstimulator that different areas appeared to be used for different colours, and he claimed to be able to map out such fixation areas on his own retina. Also, as had been suggested many years ago by Holmgren and by Fick, a small white point of light appeared in different colours according to the point on the retina used to view it.

For these and other reasons, Prof. Hartridge believes that the different colour receptors tend to be arranged in clusters and that while there are three main types of receptor—orange, green and violet receptors—there are in addition a smaller proportion of red, yellow, blue-green and blue receptors. He visualized them as having fairly narrow spectral sensitivity curves on the lines of the modulator curves reported by Prof. Granit, and although he conceded that foveal vision might be nearly trichromatic, he believes that the peripheral retina is certainly polychromatic.

Following the presidential address, shorter papers dealing with different facets of the same problem were given by Dr. K. Tansley, Dr. W. D. Wright and Dr. E. N. Willmer. Dr. Tansley reviewed the electrophysiological evidence provided by Prof. Granit's experiments. She emphasized that the existence of a receptor mechanism with a sensitivity which varied with wave-length was not in itself evidence for a colour perception mechanism, and she also pointed out that although the nerve impulse records obtained by Granit were single fibre records, the condition of stimulation in which a large area of the retina was illuminated made it virtually certain that the response was, in fact, the integrated and interacting resultant from a number of receptors. Studies on a variety of retinæ—snake, frog, cat, etc.—had revealed not only the scotopic sensitivity curve associated with the rods and the photopic sensitivity curve associated with the cones, but also much narrower curves described by Granit as modulator curves. These curves were sometimes recorded as humps on the broader sensitivity curves, sometimes as individual narrow curves; they had also been derived from a comparison between the sensitivity of the retina before and after light adaptation. Some seven modulator curves had been reported altogether, although only in the case of the cat had all seven been found in the same type of retina.

As a result, however, of the development of a polarizing technique in which records were obtained from a retina while a polarizing electric current was being passed across the retina in a given direction, Granit now appeared to be of the opinion that these seven modulator curves were in reality the result of interaction between three groups of receptors the maximal sensitivity of which occurred in the spectral regions of 450, 520 and 610 mμ.

Dr. Tansley acknowledged that these conclusions could only be extended to human vision, particularly human foveal vision, with some hesitancy; because whereas the cat's retina, for example, exhibits elaborate cross-connexions, the human fovea has much more direct connexions between receptors and optic nerve fibres. It was also true, as was mentioned in the discussion, that the animals investigated by Prof. Granit were not believed to possess colour vision; but Dr. Tansley explained that the micro-electrode technique had in practice proved much more difficult to apply to a retina such as that of the pigeon, which was capable of colour discrimination.

Dr. Wright dealt with the elements of colour-matching phenomena, and showed that, even if there were a yellow receptor, the sensation of yellowness could not be uniquely associated with its stimulation, since yellowness can also be produced by a mixture of monochromatic red and green radiations and therefore by the combined activity of the red and green receptors. It followed that any phenomenon observable with a yellow pigmented surface as test object must certainly involve the red and green receptors, since such a surface reflects light over a wide band of wave-lengths from the red to the green region of the spectrum, and the yellowness of the surface would arise primarily from the simultaneous activity of the red and green receptors. Thus the change from yellow to white with field-size could not be associated either with the presence or absence of a yellow receptor and could provide no evidence for or against such a receptor.

Again, the fact that the additive mixture of red, green and blue radiations produced colours which were too desaturated for an exact match of the colours in the spectrum was easily explained on the assumption that no physical stimulus, particularly no green stimulus, was capable of stimulating only one receptor and therefore of giving a physiologically pure response. This would naturally be the case if the sensitivity curves of the trichromatic theory were broad curves overlapping to some considerable extent. It was, in fact, quite easy to explain the calculations associated with colour-mixture experiments by analogy with an alloy having only three constituent metals.

Three processes were thus adequate to explain colour-matching phenomena and gave the simplest picture of a suitable mechanism, although trichromatic colour matching did not in itself prove conclusively that more than three types of receptor were impossible. The strongest positive argument for only three processes came from the stability of a colour match under a wide range of light and colour adaptations. If more than three processes were involved, then it would not be expected that as their relative sensitivities were changed in various ways by different adaptations, the same combination of only three stimuli would continue to provide a match of any given test colour.

Dr. Willmer approached the subject from the histological and anatomical point of view, and had been led to his hypothesis in an endeavour to explain colour perception in terms of the two types of receptor known to exist in the retina—the rod and the cone. He accepted the need for three mechanisms to satisfy the requirements of colour-matching data; but regarded the third process as arising from a distinction between the sensitivities of more centrally placed high-threshold rods and peripheral low-threshold rods, and from high-threshold rods working in combination with cones, as rod-cone units. He referred to the three chief types of bipolar cell as described by Polyak, namely, the midget, the flat and the mop bipolar, and suggested that these might be associated with the three processes. The absence of the mop bipolar in the central fovea would fit in with the dichromatism and tritanopic character of this area of the retina; but the validity of his theory hinged very much on the question of whether the fovea was populated purely by cones, or whether receptors that he has described as high-threshold rods were also present. On this point he considered the evidence was inconclusive. He also referred to Prof. W. E. Le Gros Clark's work on the lateral geniculate body where, from studies of the degeneration following lesions or damage to the optic nerve, three distinct cell groups had been observed. From considerations of their anatomical association with particular areas of the retina, Willmer suggested that group *a* of larger cells might be linked with the blue receptors (low-threshold rods) outside the central fovea, while groups *b* and *c* of smaller cells were linked with the green (rod-cone units) and red (cones) receptors both in the fovea and extra-fovea.

In the general discussion which followed, the merits of these arguments were considered at length, and it was apparent time and again that the impossibility of linking a given subjective phenomenon with a specific physiological process left the door wide open for speculation. This was illustrated, for example, by a reference to the Stiles–Crawford effect of the directional sensitivity of the retina. Until the origin of the directional sensitivity is known, the variation of the effect with wave-length can scarcely be used as very strong evidence for either this or that theory.

Prof. R. A. Morton brought the discussion to earth when he described the possible photochemical substances which might exist in the retina; and while he suggested, for example, that it was possible that retinene could exist in different ionic states in the retina, yet it was hard to believe that more than three, or at most four, light-sensitive substances could co-exist there at the same time. He pointed out that since these three or four substances might fade at different rates, the different combinations that might occur at different times could give the illusion of more than three or four primary substances. In reply to a specific question from Prof. Morton, Prof Hartridge hesitated to claim that there were sever distinct light-sensitive substances in the retina; yet if the polychromatic theory were correct, there would presumably have to be some distinctive chemica characteristics which differentiated one receptor from another.

Prof. Morton admitted that the photo-chemists had been given a clear challenge to discover what light-sensitive substances were to be found in the retina, and we have probably to become reconciled to the idea that until the more objective methods of histology, chemistry and electro-physiology have unravelled more of the secrets of the retina, theories of colour vision must remain more or less speculative. So many odd phenomena have to be explained, some quite trivial, some of fundamental importance, that the protagonist of any theory would have a hard task to convince the sceptics that his theory was complete in every respect, and he would probably be unwise to attempt it.

MARINE FISHERIES OF GREAT BRITAIN

ON September 13 a symposium on fisheries was held by Section D (Zoology) of the British Association, under the chairmanship of Prof. H. Graham Cannon.

Mr. Michael Graham opened with a paper on the theory of fishing, as it had developed since T. H. Huxley's common-sense dictum of 1883. This was that if natural mortality took more fish than the fishermen did, it was useless to regulate fishermen, whose efforts had no appreciable effect on the number of fish in the sea. In the meantime, history has shown that, in the demersal fish stocks near the British Isles, there is a persistent downward trend in catch per unit of effort, culminating in a chronic state of no profit in the 1930's. Marking experiments gave returns of 36 rising to 40 and 55 per cent of plaice returned within one year of marking. In order to put the facts in their places, it has been necessary to develop a theory of fishing. Now that eleven nations have signed the agreement of 1947, by which they will take a variety of useful measures as a start, it is necessary to state the theory in the universal language of mathematics, so that all parties can assess precisely what is advocated. The theory, as developed by the Ministry of Agriculture's Fisheries Laboratory at Lowestoft, began with Huxley's dictum about natural mortality and mortality by fishing; and added the factor of growth, because it is a fall in weight rather than in numbers that hurts the fishermen. The latest form of the theory is an equation by Beverton and Holt, which enables conservative measures, such as mesh regulation and control of fishing power, to be measured against each other in terms of the steady yield that would be obtained under different conditions. Attention was directed to Huxley's attack on any regulations that were not supported by strong evidence, and it was emphasized that the onus for showing the need for regulation should always lie on those who advocate it.

It was, therefore, quite in keeping that Mr. E. Ford should follow with a paper directing attention to the strong individualism of fishermen, as perhaps their most marked common trait. He has found the same individualism in fishery research workers, and said he suspects that it is also characteristic of fish! Mr. Ford made it clear that he regards these manifestations as important, and pleaded against their submergence in team-work. The chairman supported him in this; the present writer had not the opportunity of pointing out that strong individualism is characteristic of the members of all good teams, as may be checked by observations in any cricket pavilion. Probably Mr. Ford and also the chairman meant to attack petty hierarchies. It was clear that, as Mr. Ford sees it, the main problem of organisation of research, or of any other activity, is the use and encouragement of individuality, not its smoothing or repression. As it was put to 'Alice', "What does 1 + 1 + 1 . . . make?"; and Mr. Ford sees each 1 different from the others. It is respectfully suggested that the answer to this problem is the team, as properly understood.

In refreshing contrast to the preceding two papers, Mr. G. A. Steven gave a straightforward account of a piece of descriptive fishery research, namely, the elucidation of the seasonal cycle in the mackerel of the Celtic Sea. Contrary to general belief, the main spawning ground of the mackerel is in an area as big as Cornwall, lying over the edge of the continental shelf south of Ireland. Spawning takes place in summer, shifting to the eastward from April to June; but the movement of fish successively joining it is westerly. During the winter, the mackerel is a demersal fish, lying near slopes in the depth contours, for some reason as yet unexplained. Turning to races of mackerel in other parts of the world, Mr. Steven has found evidence of a similar behaviour pattern, correlated with depth, but naturally producing superficially different appearances where the depth contours are differently orientated. Thus, spawning in the Skagerak is crowded in to the coast, and so on. Prof. W. Garstang expressed the pleasure of the meeting at listening to Mr. Steven's vivid account of this work, and referred to his own interest in the subject more years ago than he claimed to remember. As a fishery naturalist at Plymouth, he had found that while all the European mackerel populations resemble each other closely, the North American mackerels are distinguished clearly, in samples of as few as a dozen, by having more spots in their pattern, and in other meristic characters.

Prof. J. E. G. Raymont gave an account of the now famous experiments on fertilization of Loch Sween, especially of the effects in increase of fauna of the loch bed—Chironomids, *Cardium*, etc. Bar the possibility of the effects being by ill-chance due to natural fluctuations—a point raised later by Dr. Cole in discussion—the results showed very clearly how fertilization with nitrate and phosphate had led to notable increases in benthos, time-lagged compared with the increases in plankton, and persisting for a year or so after fertilization had ceased. Increased growth of flounders and plaice followed, achieving values equal to the best natural areas. Prof. Raymont called for extension of the work to an inshore area of the more open sea; but in the discussion that followed, doubt was expressed whether a suitably self-contained area could be found.

For Mr. A. R. Margetts and himself, Mr. S. J. Holt read a paper on the effect of the War on the stock of plaice. Using Beverton and Holt's equation, already given by Mr. Graham, they had worked out what the density of plaice at the end of five years rest from fishing should be, on the basis of data of growth and mortality from the inter-war period. The estimate agreed fairly well with the actual density in 1945, obtained by back extrapolation from 1946, in which year the series of observations was renewed. However, not all the plaice in the North Sea enjoyed a respite from fishing. The younger fish on the eastern side of the North Sea suffered increased fishing from an augmented Danish fleet. The resulting thinning probably accounted for the increased growth-rate found in the younger fish, and it was only after the necessary allowance had been made that the theory gave precisely the same result as the actual, namely, five-fold. In order to take account of changes in growth-rate with changed density of stock, resulting from changed fishing-rates, the authors had used conclusions from Dr. Ben Dawes' experiments on growth of plaice in relation to food supply, supported by Margaret Brown's work on trout. With these they again applied the equation for the yield of a fishery, but with the plaice in the position of the fisherman, and the food of the plaice as its 'fish'.

In the symposium as a whole, the present writer got the impression that many zoologists preferred the more robust factual papers, and regretted the necessity for mathematical theory—useful as it has been in the more delicate and abstract sciences of physics and chemistry. MICHAEL GRAHAM

INBREEDING AND HYBRID VIGOUR IN CROPS AND LIVESTOCK

AT the British Association meeting in Brighton, Sections M (Agriculture), K (Botany) and D (Zoology) held a joint discussion on September 10 to discuss "Inbreeding and Hybrid Vigour in Livestock and Crop Improvement". The chair was taken by Sir John Russell.

The symposium was opened by Dr. J. M. Rasmusson, director of the Swedish Sugar Company's Breeding Institute, at Hilleshög, Sweden, with an account of his extensive work on the improvement of Swedish sugar beet. The chief effects of inbreeding sugar beet are to increase genetical homogeneity and to decrease productivity. At the same time, the adaptability of the plants to varying environmental conditions is lowered while the effects of environmental differences are increased: the plants are, in fact, less able to tolerate and adjust themselves to changes in external circumstances. The chemical constitution of the root, an important consideration in sugar beet, is scarcely affected by inbreeding.

The chief value of inbreeding is therefore to produce lines with specific and reliable features. It may also be of use in isolating lines in which troublesome associations between desirable and undesirable characters have been broken by changing the linkage relations of the genes. No practically useful types have been produced by continued self-pollination in Sweden; but a less-rigorous type of inbreeding, based on the use of maternal progenies between which selection is exercised, has given valuable lines. It has been observed, too, that rigorous mass selection, especially where the number of parent plants is kept small in each generation, produces the practically useful results of loose inbreeding.

When these various partially inbred lines have been raised, suitable mixtures of them can be used in bulk crosses. When this is done, nearly all the seed is from crossing though, of course, all the $\frac{n(n-1)}{2}$ crosses possible between the n lines are present more or less equally in the bulk. The bulk crosses are of commercial value because of their high yields and adaptability to environmental circumstances. The more different in origin were the parent lines, the greater the improvement on crossing; and crosses between lines produced by mass selection under different conditions generally excel those between lines raised by selection between maternal progenies. The effect of crossing, like that of inbreeding, on the chemical constitution is small. Sugar percentage may be slightly reduced though not to an extent sufficient to offset the increase in root yield.

Dr. Rasmusson concluded by mentioning a special case of crossing. Tetraploids, produced by colchicine treatment, yield 5–10 per cent less sugar than the comparable diploids. But the triploids from crossing diploid and tetraploid exceed the diploids by some 5 per cent. The triploid lines cannot, of course, be maintained from seed; but bulk crossing of diploids and tetraploids yields a mixture of the three chromosome types the average productivity of which sufficiently exceeds that of the diploid to make it commercially valuable.

Prof. R. A. Fisher next dealt with the genetical theory of inbreeding, which, as he pointed out, is essentially a means of manipulating the genetic materials so as to control their structure and composition. Inbreeding produces lines of predictable behaviour, particularly in their properties in subsequent crosses, even in respect of the numerous genes the effects of which are so small as to preclude their being followed by the mendelian method. Inbreeding is a tool the success of which has been so great in plant improvement that it can scarcely fail to achieve wide use in both plant and animal improvement in the future. Yet a theoretical understanding of its operation seems largely to be lacking, and very diverse opinions are held at present as to the reason for its success.

It is clear that the effect of inbreeding, particularly the production of an inbreeding depression which can be wiped out by one generation's crossing, must imply dominance of the genes concerned, and the genetical theory of the origin of dominance throws some light on how this could come about. The lines isolated by inbreeding differ greatly in their genetical qualities, and selection can be exercised among them at three stages in their production, namely, in the choice of individuals with which to start the inbreeding, in the choice of individuals for continuing the lines during the inbreeding, and in the choice of lines, once established as true-breeding, for use, especially in subsequent crosses. Of these, selection among the established lines is the most valuable, because the true-breeding nature of these lines permits selection based on extensive testing of a wide variety of them. Indeed, this facility offered for increasingly accurate selection is the essential advantage conferred by inbreeding. The rapid improvement in the accuracy of variety trials, made possible by replicated and randomized field designs, has played an important part in refining the selection which has been so successfully practised in the production of hybrid maize.

Mr. G. M. L. Haskell, who followed Prof. Fisher, gave an account of the theory and practice of hybrid maize production. Hybrid maize represents so great an advance over the open-bred varieties which preceded it that it has now replaced the latter virtually completely in the corn belt of the United States. Maize is naturally a cross-pollinator, and genetically the plants are mostly heterozygous. Ordinary methods of selection had shown themselves incapable of materially improving the open-bred varieties of maize before the new methods were introduced. The introduction of the inbreeding technique has led to the production of a great variety of lines which, though all showing inbreeding depression in greater or lesser degree, are uniform and virtually true-breeding and have satisfactory plant characters. Hybridization of inbreds, which is made easy by the monœcious habit of the plants, produces offspring the hybrid vigour of which is often such that they surpass in yield not merely the inbreds themselves but also the open-bred varieties from which these inbreds were produced. Every one of the hybrid plants is a potential yielder, and the hybrid families are uniform in appearance, time of maturity and disease resistance. The more diverse the parentage of the inbreds, the more likely they are to combine well in giving high-yielding hybrids. Combining properties vary from inbred to inbred and represent a character for which breeding can deliberately be practised.

Mr. Haskell described the commercial methods used in the United States for inbreeding and hybridizing maize, both in sweet corn where first crosses are used for commercial production, and in field corn where double crosses, made between two first crosses, are preferred. The special problems of breeding maize suitable for Great Britain in regard to photoperiodism and cold-hardiness were mentioned in conclusion. A feature of Mr. Haskell's paper was the wealth of lantern slides with which all its points were illustrated.

In the fourth contribution to the discussion Dr. H. P. Donald dealt with the use of inbreeding and crossbreeding in livestock production. Breed crossing is not an uncommon practice in animal husbandry. Sometimes it is indiscriminate, particularly where, as in Britain, many breeds are kept. Such crossing is not intrinsically undesirable though it must always indicate a lack of purpose in the breeding aims. Other crosses are made deliberately for purposes such as that of distinguishing the sexes at hatching in poultry. Crossbred animals may also be better fitted to particular environments. For example, the Zebu-cattle crosses in northern Australia combine good heat tolerance and quick growth; but have lost some popularity because of their intractability in handling. In the extreme case breeds might be kept as inbreds solely for the purpose of producing crossbreds. A further type is cyclical crossbreeding, where successive generations are mated to two, three or four breeds in turn. This should conserve the greatest part of any heterosis that the crossbreeding could give without the necessity of always going back to the pure breeds for crossing; but it has yet to be shown that the heterosis so obtained is worth while.

Inbreeding has not so far been widely tested as a preliminary to crossbreeding in livestock, because of the great experimental expense. It is known, however, to result in depression of such characters as viability, fertility and milk production. Many defects like scrotal hernia and cleft palate also appear. Slow inbreeding under selection might help to overcome these troubles, but many of the lines must in any event be discarded. The exploitation of inbreeding followed by crossbreeding is too expensive for the ordinary farmer and must require a new breeding organisation. This has been developed for the 'Hyline' poultry in the United States. These birds resemble double-cross maize in their method of production and they cannot be successfully bred on by the farmer. They show hybrid vigour more in the rate of survival than in the egg production of surviving hens.

The complementary use of inbreeding and crossbreeding in animals has potentialities in three ways: to exploit hybrid vigour, to fit the requirements of new territories, and to improve breeds within their own limits when simple selection ceases to be effective. It remains to be demonstrated, however, in each case whether the gain in production will pay for the labour and expense of the method.

The final paper of the meeting was given by Dr. K. Mather, who discussed the genetical principles and problems of inbreeding and crossbreeding as a method of plant and animal improvement. In inbreeding plants, such as wheat, peas and tomatoes, homozygous lines of uniform excellence can be maintained by the natural breeding system of the crop. This is not possible with crossbreeders, in which varieties and breeds, though in equilibrium from generation to generation, must always consist of a heterogeneous collection of heterozygous individuals. Genetical variation is inevitable and the average of the variety must in consequence always be below the best. The homozygotes produced by inbreeding are always poor in such species. Uniform and predictable groups of heterozygotes can, however, be obtained by artificially crossing these homozygous lines. Thus it is the aim of the method of inbreeding and crossbreeding deliberately to produce heterozygotes uniformly approaching the best individuals of the open-bred varieties and so, as groups, excelling the average of the varieties; and further to produce these heterozygotes consistently generation after generation.

Five problems arise with this method of breeding. First, there is the great multiplicity of inbred lines which can be raised and must be tested. In the past the desirable inbreds have been discovered by trial and error. Those which give the best hybrids are not, in fact, always themselves the most productive inbreds. Combining ability is the critical character of the inbreds, and it is on this character that they must mainly be selected. Quicker methods are needed for sorting out the lines with valuable combining properties from the mass of their less useful fellows.

The second problem is raised by the poverty of the inbreds themselves. They are expensive to keep, and their immediate yield of hybrid offspring when crossed is low, so that hybrid production is costly. Various methods, such as double-crossing and top-crossing, are used to overcome this latter difficulty without sacrificing the chief benefits of the system of breeding.

The method of convergent improvement has also shown itself capable of raising the vigour and productivity of the inbreds themselves.

Thirdly, there is the problem of making the necessary controlled crosses. This is easy in diœcious animals and in monœcious maize; but plants with hermaphrodite flowers require special methods. Cytoplasmically controlled male-sterility has been used for this purpose in onions, and bulk crossing is being exploited in sugar beet.

The fourth problem is raised by the very uniformity of the inbreds and their hybrids. Where only inbreds are maintained there is a risk of loss of the valuable reservoir of genetical variation which is to be found in the open-bred varieties, and in maize special collections of the old types have become necessary to provide sources of future breeding material. In the hybrids the danger of complete genetical uniformity is that it may result in total loss of the crop through a short period of adverse weather, the effect of which on a more variable stand would be much less serious. The production of double-cross hybrids goes some way to overcome this difficulty.

Finally, there is the question of whether the raising and crossing of inbreds pays for itself. In maize and sugar beet it certainly does; but elsewhere the answer is less clear. It seems, in fact, that the answer will not be the same for all species in all circumstances, and any investigation of the practical possibilities of inbreeding and crossbreeding must therefore pay due attention to the economic aspect.

K. MATHER

THE WORLD FEDERATION OF SCIENTIFIC WORKERS

THE first General Assembly of the World Federation of Scientific Workers was held in Czechoslovakia during September 21–25, as guests of the Czechoslovak Association of Scientific Workers. It was attended by thirty-three delegates and observers from thirteen countries (Austria, Britain, Bulgaria, Canada, China, Czechoslovakia, Denmark, France, Greece, Hungary, Poland, South Africa and the United States). Observers on behalf of Unesco and the World Federation of Trade Unions were present.

The business sessions were held in the Castle Dobřiš, the magnificent country palace belonging to the Czechoslovak Syndicate of Writers, which is about forty kilometres from Prague.

The Assembly was opened by the president of the World Federation of Scientific Workers, Prof. F. Joliot-Curie. Messages of welcome and greeting were received from the Czechoslovak Ministers of Foreign Affairs, Education and Information, Unesco, the World Federation of Trade Unions, the Czechoslovak Trade Unions, the Czechoslovak Academy of Sciences, and other personalities and institutions.

The chief business of the second session was the presentation and discussion of the secretary-general's report. The secretary-general, Mr. J. G. Crowther, reviewed the activities of the World Federation of Scientific Workers during the two years of its existence. He described how, at the end of the Second World War, associations of scientific workers had spontaneously come into existence in various countries. The formation of a Federation was desirable for the exchange of views, and the formation, so far as possible, of agreed opinions on all questions affecting scientific workers as such.

The World Federation now contains eighteen affiliated organisations, in fifteen countries drawn from all the five continents. The total membership of individual scientific workers is more than twenty-four thousand.

The World Federation has been recognized by Unesco as one of the non-governmental international bodies interested in its work. Accordingly, it was invited to send representatives to the Second General Conference at Mexico City, and to Unesco Commissions on the Popularization of Science and its Social Relations. These representatives proposed that Unesco should found fellowships for research on the social relations of science, an innovation that has been accepted.

The World Federation has initiated a new kind of international ceremony. These are celebrations of great men of science not in the country of their origin. The first was the London celebration of Langevin, the second was the Paris celebration of Rutherford. The third will be in 1949, on the centenary of the birth of Pavlov. The Langevin proceedings have been published, and those of the Rutherford ceremony are in the press.

The resolutions and proposals submitted to the first Assembly were analysed and discussed by four working commissions, dealing respectively with: (*a*) The Organisation and Social Responsibility of Scientists; (*b*) Atomic Energy, Secrecy and Peace; (*c*) Reconstruction, Colonial Countries, and Natural Resources; (*d*) A World Federation Journal, and Finance.

The reports of the four commissions, after amendment and verbal improvement, were accepted by the Assembly in plenary session. The resolutions dealt with the persecution of scientific workers, the unity of men of science against war, the co-ordination and improvement of abstracting services, international holiday camps for scientific workers, the control of atomic energy, secrecy in science, distribution of radioactive isotopes, scientific development in colonial countries, utilization of world resources, the foundation of a Federation journal, and other topics.

A special resolution was passed welcoming the formation of the Permanent International Committee for Peace by the Wroclaw Cultural Congress, and wishing it all success in its struggle for a peaceful world.

The decision to launch a World Federation journal was one of the most important. It is hoped that publication will begin soon, and that the first number will be devoted mainly to a report of the proceedings of the Assembly.

The draft "Charter for Scientific Workers" was discussed in plenary session, and emendations from affiliated associations were incorporated. The Charter was then adopted. The Czechoslovak Minister of Education, M. Z. Nejedlý, who is also president of the Czechoslovak Academy of Sciences, was present at this session. The chairman, Prof. J. Bělehrádek, remarked after the vote that the occasion was historical, for it was the first time in the history of science that scientific delegates from all quarters of the globe had agreed on a definition of their duties and rights as scientific workers.

On the night of September 22 a public meeting on "Science in the Modern World" was held in the Lucerna Hall in Prague. Two thousand persons bought tickets for this meeting. Speeches were delivered by Prof. F. Joliot-Curie (France), Mr. C. M. Liu (China), Prof. S. Maximos (Greece), Dr. K. Z. Bratanoff (Bulgaria), Prof. J. D. Bernal (Britain) and Prof. A. Kolman (Czechoslovakia). Several brilliant speeches were made; but one of the most remarkable was by Prof. Z. Nejedlý, in moving the vote of thanks to the speakers. He revealed an equal understanding in addressing the men of science on one hand, and wit and humour in speaking to the general audience on the other. After the meeting he gave a reception in honour of the Assembly, which was attended by Czechoslovak personalities, the British Ambassador and other members of the Diplomatic Corps.

The Czechoslovak Association of Scientific Workers entertained the members of the Assembly to a two day tour of their country, in which no less than six hundred kilometres were covered by bus. The main visits were to the Bata works at Zlín, and to Hradec Králové. The famous boot and shoe factory, now nationalized, is at the base of high wooded hills. The architecture is in the most modern functionalis style. Extensions are being built at a great speed floors being added to buildings at the rate of one a fortnight. The roof of the newest factory is to be a helicopter landing stage. Bata has its own twelve-story hotel. Many of its workers are housed in cubic villas on garden-city lines, and in flats. More than one thousand new flats are under construction. It was stated that Bata employs thirty-two thousand workers, and has a daily output of a hundred thousand pairs of boots and shoes—ninety per cen for export. There is a considerable research organisation, including consumer research. New styles ar tried out on a large scale by employees, who are given the footwear free, and are then asked to report on attractiveness, comfort, wear, etc.

Members of the Assembly also visited the new Medical Faculty, created at Hradec Králové in 1945. The building, which had been a military school, and had been occupied by the Red Army, was vacated by the Soviet Commander in order to provide accommodation for the new school, with the comment that it was fitting that Mars should make way for Athene.

After visiting the Medical Faculty, the members were received at the Institute of Glass Technology, a research and consulting centre for one of Czechoslovakia's chief industries. J. G. CROWTHER

NEWS and VIEWS

Experimental Zoology at Manchester :

Dr. Ralph Dennell

THE science of zoology underwent a profound change at the end of the First World War. The orthodox approach to the subject through a study of comparative anatomy was largely abandoned, and all energies were devoted to the new outlook afforded by experimental zoology. Despite this complete change-over, no new academic posts were created to cater for this new method of approach. For a short time, there was a readership at Cambridge, but that was all. Now, to fill this obvious want, the University of Manchester has established a full chair in experimental zoology, to which Dr. Ralph Dennell has been appointed. Dr. Dennell has the advantage of having made his name first of all as a functional morphologist. He commenced work on the feeding mechanism of various Crustacea, and later turned his attention to the luminous organs of certain deep-sea prawns. During the Second World War, he undertook a study of the feeding mechanism of the grain weevil, and this led him to an experimental investigation of the process of hardening of the insect cuticle, a problem which he is extending to the whole of the Arthropoda. At present, he is in Bermuda, with a Leverhulme fellowship, studying deep-sea luminous forms.

Assyriology at the British Museum :

Dr. Sidney Smith, F.B.A.

IT has been announced that Dr. Sidney Smith has retired from the post of keeper of the Department of Egyptian and Assyrian Antiquities at the British Museum, and has been succeeded by Mr. C. J. Gadd, formerly deputy keeper of the Department. Dr. Sidney Smith entered the British Museum in 1914 and has been keeper since 1930. There are probably few living Assyriologists who can speak with authority, as he does, not only on textual and philological matters, but also on every subject connected with Near Eastern and Egyptian archæology. He was one of the first to correlate the complicated stratigraphical and epigraphical data yielded by recent excavations in Syria and the Hatay, and his new scheme of chronology published in 1940 is being accepted by an increasing number of scholars. He is a controversialist who does not tolerate loose thinking; but serious students have always had reason to be grateful to him for his constant readiness to place the fruits of his learning at their disposal. It is understood that as professor of ancient Semitic languages and civilizations at the School of Oriental and African Studies, University of London, he hopes to have more time in future for his own researches.

Mr. C. J. Gadd, F.B.A.

MR. C. J. GADD, who in terms of service in the British Museum is only five years junior to Dr. Smith, is an Assyriologist of no less eminence than his predecessor, and is a profound and erudite scholar, whose deep understanding of the ways of thought of the Babylonians and Sumerians is exemplified in his Schweich Lectures, recently published under the title "Ideas of Divine Rule in the Ancient Near East". With his generous and self-effacing personality, he brings to his new appointment the goodwill of his staff and of all who know him.

Festival of Britain, 1951

GENERAL LORD ISMAY, chairman of the Council of the Festival of Britain, 1951, presided at a meeting on October 14 to announce progress in the plans for the Festival. Mr. Gerald Barry, director-general, emphasized that it is hoped to mark 1951 in three ways: by events centrally organised and financed by the Festival organisation itself; by events organised by other interests, which may be associated with and assisted by the Festival authorities; and by unofficial events throughout Great Britain. There is to be a central exhibition in London on the south bank of the Thames between the County Hall and Waterloo Bridge; the river front is to be cleared and a concert hall built on the site. The exhibition itself will be in temporary fabric structures of a new type; it will be on a small scale and an attempt will be made to tell the story of British life and achievement. It was emphasized that it will not be a trade fair. The Council of Industrial Design will be responsible for selecting contemporary industrial exhibits. A Council of Science and Technology, specially created for the Festival, will ensure that scientific achievement will be adequately represented both in the central exhibition and in other ways. An Architectural Exhibition, elsewhere in London, will take the form of a full-scale cross-section of a residential area in various stages of building, which can be completed and handed over for actual use after the Festival closes. There will also be one or more travelling exhibitions visiting the principal cities of the country; and it is hoped to co-operate with bodies holding annual meetings, such as the British Association. Finally, the Vice-Chancellors of the Universities of Oxford, Cambridge and London have been invited to arrange special vacation courses in the summer of 1951 in subjects relevant to the main theme of the Festival. In this way, it is hoped to demonstrate the contribution of British thought in philosophy, literature, religion and science to the progress of civilization.

Research and Recovery

MR. HERBERT MORRISON, Lord President of the Council, addressed the chairmen of councils and directors of the industrial co-operative research associations at a conference in London on October 15. The express purpose of this conference was that the delegates should acquaint the Government of their progress and difficulties in research so that the findings could be integrated into Great Britain's overall economic programme. Mr. Morrison believes that the first problem of economic recovery is one of increased productivity, and the key to this is to be found in more knowledge—knowledge both of technical processes and also of human relationships. The Government is fully aware of the importance of the issue and is prepared to support State and private research with every financial help; thus the trend of increase in cost—£470,000 in 1938, £2 millions last year and an estimated £2½ millions next year—is not a matter for concern but a sign of the ever-growing importance of research and a pointer to bigger things to come. Recent material results have convinced Mr. Morrison that the money is well spent, and he referred, for example, to the technical advances made in pottery firing operations, infra-red drying of paints, fitting of shoes, adjusting of peak electrical loads, production of linen, improvement of iron foundries and development of 'nodular cast-iron', design of more efficient domestic grates, scientific research into better houses, and the improvement of road surfaces. It is important that manufacturers should bear in mind the improvement of quality and lowering of costs in addition to increased productivity. All these problems can be solved by more scientific investigation, and Mr. Morrison considers that research is the spearhead of the advance of industry by which we will determine whether we are going to hold our place in competitive world industry or degenerate into a third-rate Power. Not only must the value of research be recognized, but also the conditions of scientific workers must be improved and their status acknowledged. Responsible people do realize these points, but are they fully understood by the general public? The research associations must publicize their activities and see that the world knows of the excellent results being obtained by British research effort.

Operational Research Club

About a year ago, a number of men of science interested in operational research began meeting together in the rooms of the Royal Society to discuss the development of methods and the application of this field of science. Papers were read and discussed in connexion with road traffic, productivity in the cotton industry, use of fertilizers by farmers, the organisation of inspection in the steel industry, etc. An "Operational Research Club" has now grown out of these meetings, and a healthy programme of papers for this session has been planned. In order to maintain the informal nature of the meetings, it has been necessary to limit the membership; but it is intended to include representatives from most of the operational research teams working in industrial and other civil fields, together with some from the defence services. The honorary secretary of the Club is Mr. D. Neville-Jones, 24 Rutland Gate, London, S.W.7.

Motor Industry in Britain

A clear picture of the British motor industry is presented in a broadsheet prepared by Political and Economic Planning (No. 284). The broadsheet traces first the development of the industry before the War, examining factors such as taxation which influenced demand in the United Kingdom and the growth of the Nuffield Organisation, the Ford Motor Co., the Austin Motor Co., Vauxhall Motors, the Rootes Group, and the Standard Motor Co. The effect of conversion to war demands and subsequent reconversion is then described, and, after a review of the post-war structure and home demand, the labour force of the industry is analysed, and its trade organisations and export markets are considered. The broadsheet makes no recommendations as to future policy, but indicates that if the shortage of foreign exchange could be left out of account, there is sufficient shortage of vehicles in the world to give both Britain and the United States ample scope for some time to come. Such comparison with pre-war figures as is practicable suggests that the industry's labour force is about 25 per cent greater than before the War.

The Original Wright Aeroplane

The original Wright aeroplane of 1903—the first power-driven man-carrying aeroplane to make a free, controlled and sustained flight—was lent by Mr. Orville Wright in 1928 for exhibition in the Science Museum, London, for an initial period of five years. On October 18 it was taken down for packing in crates in readiness for its return to the United States. This machine was designed and built by the brothers Wilbur and Orville Wright at Dayton, Ohio, in 1903, and was flown at Kitty Hawk, North Carolina, on December 17. The first flight lasted 12 sec. and was made in a wind of about twenty miles per hour, the machine being piloted by Mr. Orville Wright; altogether four flights were made on the morning of that day. The last flight was one of 59 sec., when the distance covered was 852 ft.; the machine was then overturned by a gust of wind while left unattended, and the damage caused prevented further experiments at that time. After these first flights, the aeroplane was preserved in the Wright Laboratory at Dayton. Certain parts which were damaged were replaced by Mr. Orville Wright himself, and the machine was restored to its original condition. An exact replica of the aeroplane has now been made and will be exhibited in its place at the Science Museum. Dr. H. Shaw, director of the Museum, is to accompany the machine to the United States, where it will be preserved in the National Air Museum, Smithsonian Institution, Washington, D.C. It should arrive there in good time for the forty-fifth anniversary of its first flight on December 17, 1903.

Economics and State Control

Prof. G. C. Allen's inaugural lecture at University College, London, on March 4, 1948, which has now been published (London: H. K. Lewis and Co., Ltd. Pp. ii+18. 2*s.* 6*d.* net), emphasizes that while the trend of economic opinion in pre-war days was in favour of a more active intervention by the State in economic affairs, such intervention was not inconsistent with the preservation of the system of private enterprise; it was deemed necessary for improving the operation of the system. Present policy, however of State intervention goes much further than the achievement of 'full employment', an acceptable distribution of the national income, and the promotion of structural adjustments in industry by fiscal or financial measures. Prof. Allen devotes mos of his lecture to an examination of the economic implications of the policy at present being pursued both in the nationalization of industry and in the guidance of private industry by substitutes for the compulsion of the market. He points out the importance in industries that depend to any extent upon innovation of being able to attract the outstanding personalities with initiative and organising capacity the administration and efficiency of such industrie will suffer under nationalization if such men are no longer attracted by the conditions of service. Similarly, he discusses the difficult question of effective Parliamentary control over the operation of public monopolies, and suggests that the safeguard of publicity can and should be made fully effective.

Prof. Allen offers no answer to the fundamental question whether it is possible for the State to formulate far-reaching plans for the disposition of economic resources intended to promote objectives of which men in their political capacity approve, and at the same time to afford adequate opportunities in the industrial sphere for the free movements of the mind and will, without which progress is in jeopardy. Certain dangers and problems, such as those of economic discipline, of the transfer of important categories of decision from the individual to the bureaucracy, and the establishment of an administrative machine capable of reaching speedy and wise economic decisions in those fields, and the danger of perpetuating the *status quo* in circumstances inherent in 'gentlemen's agreements' between the Government and organised bodies in industry, are indicated. Prof. Allen, while indicating the limits and dangers of such methods, believes that we are likely to be so hard put to it to find help in pursuing the middle way that we should not reject any method which offers even moderate prospects of success.

Permanence of Residence as a Social Factor

A PAPER by Dr. H. M. C. Luykx, "Family Studies in the Eastern Health District: IV. Permanence of Residence with Respect to Various Family Characteristics", reprinted from *Human Biology*, is one of several studies in a district of the city of Baltimore. Its findings are summed up in a table showing the family characteristics associated with the highest and lowest proportions of families remaining in the district between the triennial censuses of 1933, 1936 and 1939. The highest proportion of permanence was found among whites, owning their houses or paying the highest rent, with children and several wage-earners in family, where the family head was a skilled worker or foreman, middle-aged, foreign born, and not highly educated. With the present concern over labour mobility between industries, this study has considerable 'social significance'. Education, and renting rather than owning houses, seem indicated as favourable factors that social policy can control.

Directory of Natural History Societies

IN December 1943 the Committee of the Amateur Entomologists' Society agreed to compile a Directory of Natural History Societies. Quite independently, Miss R. S. Shove suggested in *School Nature Study* of January 1944 that a list should be prepared of school natural history societies and field clubs. As a result it was decided to trust the entire work to the Amateur Entomologists' Society, the School Nature Study Union agreeing to assist in the preparation of a schools section. In its early stages the compilation was directed by W. G. Rawlings; he was later succeeded by H. K. Airy Shaw. The Directory has now been completed and contains a list of all organisations with any biological interests, excluding bodies of an economic or professional nature. All societies, past and present, of which the Society could find any record in the British Isles, have been included. These have been arranged first to give information about national societies and then local societies, arranged in order of counties. The material arranged under each entry in the Directory is sufficient to guide naturalists in a distant county to a group of like-minded individuals. Not the least important parts of the Directory are the particulars of so many school natural history societies. The Directory can be obtained from the Secretary, Amateur Entomologists' Society, 1 West Ham Lane, London, E.15.

Nairobi Scientific and Philosophical Society

IN spite of the speed of modern communications, the sense of isolation arising among scientific men working in the Colonies and elsewhere overseas is still very real; one way of mitigating the difficulty is the formation of local scientific societies. The Nairobi Scientific and Philosophical Society is such a body, which arose from the need for co-operation between various scientific and technical officers working in Kenya. A meeting was held at Nairobi on April 9, 1947, at which the chairman, Mr. A. Walter, stressed the need for a central meeting place for scientific men, and the first formal meeting took place a month later. Now the Society has been able to issue vol. 1, part 1, of its *Proceedings*, and to claim a membership of fifty within six months of formation; this shows a very creditable interest among the necessarily small number of scientific and technical workers within reach of Nairobi. The *Proceedings* includes accounts of five meetings held by the Society; the subjects dealt with include *radio-sonde* in meteorology, the sociologist in industry, primitive agriculture in the modern world, development planning for the African and hormone weed-killers. The sociological bias shown is accounted for by the facts that advantage had to be taken of the availability of visiting guest speakers, and that the Society itself has arisen in a country where the development of a primitive people is taking place at an unprecedented pace. The Society is to be congratulated on the progress it has made as a centre for the discussion of problems of broad scientific and technical interest in Kenya. The officers of the Society are: *President*, A. Walters; *Vice-Presidents*, Dr. E. B. Worthington and V. A. Beckley; *Joint Honorary Secretaries*, W. A. Grinstead, P.O. Box 931, Nairobi, and H. E. Watson, P.O. Box 560, Nairobi; *Honorary Treasurer*, Dr. D. Harvey; *Honorary Librarian*, Dr. H. C. Pereira.

Earthquake in Iran

ON October 5, a great earthquake shook large areas in the province of Khurasan in north-eastern Iran, together with parts of Russian Turkestan. The large area of destruction appears to indicate either that the depth of focus of the shock was greater than normal, or that there was more than one shock. Two hundred people are reported killed and thousands injured at Meshed, with two hundred killed at Dereges. Askhabad, a Russian town with 150,000 inhabitants, suffered severely, four hundred people being reported killed. Six thousand injured people have been evacuated by air, and a temporary water supply has had to be organised to replace the town's water supply disrupted by the earthquake.

The area is a particularly seismic one, 140 earthquakes of varying intensity having been experienced during the last seventy years, and large earthquakes having occurred, according to Sir Arnold Wilson, at Kuchan in 1852, 1871, 1872, 1893 and 1895, at Meshed in 1673 and 1895, and in the whole area in 1929. This latter shock was also reported in *Nature* of May 11, 1929. On May 1, 1929, twelve distinct shocks were felt within twenty-four hours at widely separated points, running from Bandargaz to Kalat. The towns of Shirvan, Bujnurd and Jajarm were severely damaged, and a thousand people were killed in Askhabad. A cleft three yards wide is reported to have been opened between the towns of Khaki and Bagham, to a distance of eighteen miles. The total Persian casualties were 3,253 killed, 1,121 injured, 88 villages destroyed and 6,542 cattle injured. Further news is awaited concerning the present earthquake.

International Council of Scientific Unions

THE annual meeting of the Executive Committee of the International Council of Scientific Unions was held at Brussels in September, Prof. E. Borel presiding in the absence of the president, Dr. J. A. Fleming. A resolution from the Royal Society was adopted, that all adhering bodies, national academies and scientific unions be consulted before the Executive Committee accepts any new union. A resolution from the United States asking the Council to consider its constitution and the distribution of subjects covered by the Unions was referred to a committee in the hopes that a report might be available for discussion at the next General Assembly of the Council at Copenhagen during September 14–15, 1949. New joint commissions between the unions were agreed upon to deal with standards and units of radioactivity, spectroscopy, and high-altitude research stations. The adhesion of one new country, Pakistan, was reported. The recommendation from the Committee of Science and Social Relations that a journal should be started by the Committee was referred to the General Assembly. Dr. Establier was reappointed liaison officer with Unesco; representatives of Unesco present at the meeting were Prof. P. Auger and Dr. Wang-hsi-chin.

International Commission on Glass

THE International Commission on Glass held its first post-war meetings at Sheffield and Buxton during September 30–October 2 under the presidency of Prof. W. E. S. Turner. Decisions were taken to revise the constitution of the Commission, and arrangements were made for the preparation of scientific and technical reports on subjects of fundamental importance in glass technology. Until the adoption of the new constitution, the following comprise the International Commission: Prof. A. H. M. Andreasen (Denmark); Prof. J. A. de Artigas (Spain); Dr. B. P. Dudding (Great Britain, *honorary secretary*); Dr. M. Fanderlik (Czechoslovakia); Prof. P. Gilard (Belgium); Dr. J. C. Hostetter (United States); Dr. B. Long (France); Dr. H. Maurach (Germany); Dr. Atma Ram (India); B. Simmingsköld (Sweden); Dr. J. A. Stevels (Holland); Prof. W. E. S. Turner (Great Britain, *president*).

American Physical Society: Division of Fluid Dynamics

THE Division of Fluid Dynamics of the American Physical Society, which was established by the Council of the American Physical Society in June 1947, has been organised, and the following have been elected members of the Executive Committee: Jesse W. Beams, Howard W. Emmons (*secretary-treasurer*), Theodor von Kármán, Hugh L. Dryden (*vice-chairman*), Paul S. Epstein, Raymond J. Seeger (*chairman*), and John G. Kirkwood. The first meeting of the new Division took the form of a one-day symposium on June 23, when the Division joined with the University of California at Los Angeles, the University of Southern California, and the California Institute of Technology as part of a three-day meeting to discuss heat transfer and fluid dynamics.

British Museum (Natural History)

THE southern half of the Invertebrate Gallery (which used to be known as the Starfish Gallery) in the Zoological Department of the British Museum (Natural History) has now been re-opened. The Gallery was dismantled during the War, and an entirely new arrangement of starfishes and other Echinoderms has been prepared, showing many species in their vivid natural colours. Their usefulness to man and their methods of feeding and breeding are among the subjects illustrated in the new exhibit. In addition to Echinoderms the Gallery is being used temporarily to house a full-sized model of a giant squid, and a small selection of shells. These have been chosen mainly for some interesting peculiarity; there is, for example, a display of venomous cone shells. A series of common British shells is also exhibited. Certain groups of small invertebrates are also on view here, notably the great group of worms, including earthworms, leeches, many marine forms and parasites. Another new feature is a large-scale relief map coloured to indicate the main movements of the oceans, and the zoo-geographic regions into which the land masses are usually grouped for purposes of biological study.

National Certificates in Textiles

THE Textile Institute, which is jointly responsible with the Ministry of Education for the award of national certificates in textiles, announces that this year there were 131 entrants for the ordinary certificate, of whom 109 passed, and 85 for the higher certificate, of whom 82 were successful. Fifteen distinctions were obtained in the Higher National Certificate examination. Of the 191 successful candidates, 125 studied cotton subjects, 46 woollen and worsted, and 20 studied general textile subjects.

University of Sheffield: Appointments

THE following appointments have been made in the University of Sheffield: Dr. William Hobson, senior lecturer in preventive medicine in the University of Bristol, to the newly instituted chair of social and industrial medicine; Miss Ellinor I. Black, senior lecturer in the Department of Social Science, University of Liverpool, to be director of the newly instituted Department of Social Studies; S. Armstrong, lecturer in civil engineering; Dr. A. E. Beet, at present demonstrator in fuel technology, to be lecturer in fuel technology; A. W. Nicholls, assistant lecturer in glass technology; P. H. Price, research assistant to the professor of fuel technology; James S. Hough, research demonstrator in botany; P. Wright, Glass Delegacy research fellow.

Announcements

SIR WALTER MOBERLY, chairman of the University Grants Committee, will deliver the Rede Lecture in the University of Cambridge on November 18. He will speak on "Universities and the State".

FOR the future, the Universities Bureau of the British Empire will be known as "The Association of Universities of the British Commonwealth". Its new address is 32 Woburn Square, London, W.C.1 (Telephone No.: Museum 4578/9).

Multiplication of Bacteriophage

As part of a study of how viruses grow, we have been making series of electron micrographs which demonstrate essential steps in the multiplication of the virus-like bacteriophages.

This multiplication has been most easily seen in certain experiments with the *T*(2) bacteriophage against *E. coli.* Frequently transferred bacterial cultures less than two hours old were mixed with filtered bacteriophage suspensions of high titre and incubated for periods ranging from 0 to 30 minutes. At the end of the desired interval, interaction was arrested by chilling the mixture in ice water. The sediment obtained from it by centrifugation was formalinized and washed by repeated sedimentation. In final aqueous suspension it was mounted on collodion-covered grids and shadowed[1] with chromium or palladium.

Electron microscopic observation showed that young bacteria are lysed very soon after coming in contact with the particles of bacteriophage. All studies were carried out with an RCA Type EMU 2 microscope. Ruptured bacteria are common from cultures chilled immediately after mixing. In photographs such as that of Fig. 1, their protoplasm can be seen flowing out and engulfing the infecting particles. Foci of bacteriophage multiplication are apparent as dark clumps in similar cellular residues if incubation has proceeded for a few minutes before chilling. These foci, seemingly developed from the infecting particles, are at first few in number (Fig. 2). They are more numerous after longer incubation and after about 15 min. separate, presumably; newly formed particles are also seen distributed throughout the remains of the bacterial protoplasm. Both clumps and single particles increase still further with incubation, and eventually the regions of lysed protoplasm are more or less completely covered by the bacteriophage particles that have, through their growth, used up most of the protoplasm. As Fig. 2 suggests, detail cannot usually be discerned in the opaque clumps. Where, however, protoplasm has been washed or eaten away, they can be seen to consist of groups of particles (Fig. 3). These particles are commonly smaller than the average and are associated together in ways that suggest developing forms. Many of the free particles seen after short periods of incubation resemble the particles of these groups and, like them, are small.

Information from such electron micrographs, of which several hundred have now been obtained, indicates that these bacteriophage particles increase in number at the expense of bacterial protoplasm by a process that in many ways resembles the multiplication[2] of coccoid bacteria. Apparently most of this growth and multiplication takes place in the protoplasmic masses liberated by lysis rather than in bacteria which are still intact. In these respects bacteriophage can be thought of as a parasite living on bacterial protoplasm. It has been, and will continue to be, difficult to observe many details of this multiplication, because it necessarily occurs within masses of bacterial protoplasm the molecular texture[3] of which is not much finer than that of the developing bacteriophage.

Particles of bacteriophage resemble micro-organisms in other ways. Thus they have a complex organisation that includes a flagellar appendage and a head consisting of particles enclosed in a well-defined membrane. The amino-acid composition of bacteriophage protein is significantly different from that of its host[4]. Additional evidence about the 'living' nature of bacteriophage can be obtained from studies of its rate of diffusion. A number of years ago Northrop[5] found that a sufficiently dilute staphylococcus bacteriophage suspension seemed to diffuse faster than would be expected from its particle size. Recent measurements by Polson and Shepard[6] in this Laboratory, by a different method, have indicated that dilute coli bacteriophages also diffuse abnormally rapidly. The new data, however, are not entirely satisfied by Northrop's assumption of dissociation into small active fragments, and it is conceivable that they point to an independence of particle movement

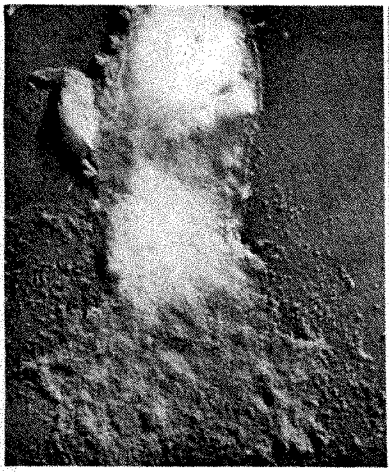

Fig. 1

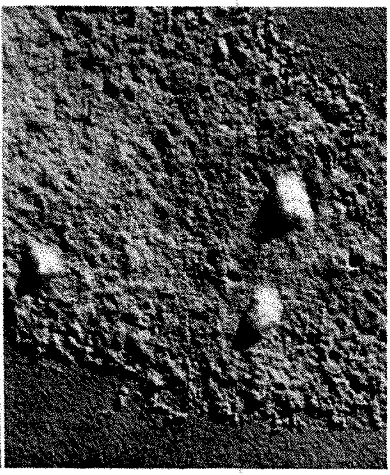

Fig. 2

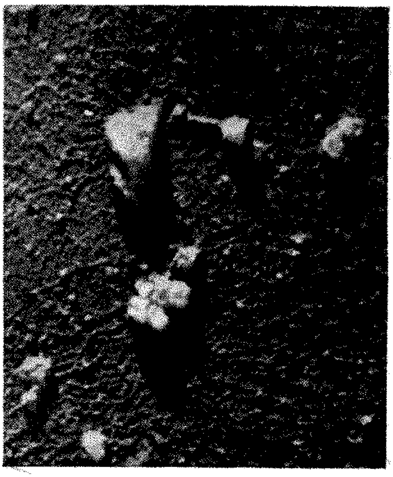

Fig. 3

Fig. 1. A colon bacillus being lysed under the action of *T* (2) bacteriophage. Granular protoplasm flowing from the lower part of the organism has partly engulfed a bacteriophage particle at the left. (× *c.* 17,000)

Fig. 2. Protoplasm from part of a lysed colon bacillus showing three opaque centres of multiplication. (× *c.* 17,000)

Fig. 3. Two clumps of developing bacteriophage particles free of enveloping protoplasm. The several developing particles in the lower clump and the single mature particle to the right of the upper clump are essentially clear. (× *c.* 40,000)

that presumably would be sustained by some kind of metabolic activity.

Bacteriophages are known which have diameters as small as *c.* 100 A. If they multiply in the autonomous fashion observed for the $T(2)$ bacteriophage, then 'living' self-reproducing objects exist which are considerably smaller than the molecules of such well-defined proteins as the hæmocyanins and erythrocruorins.

These studies are being described in more detail in papers appearing in the *Biochimica et Biophysica Acta.*

Ultra-Violet Microscopy of Living Malignant Cells

PREVIOUS work on the ultra-violet microscopy of living cells has led to conflicting conclusions as to the value of this technique in cytological research. Thus, Wyckoff, Ebeling and Ter Louw[1] reported that Feulgen staining, which demonstrates desoxyribose-nucleic acid in fixed cells, duplicates the results obtained by the ultra-violet microscopy of living cells. "Ultra-violet microscopy can be considered as the equivalent of a vital staining specific for formed chromatin" was their conclusion. More recently, in *Nature*, Brumberg and Larionow[2] maintained that desoxyribose-nucleic acid is present in the nucleus of living cells in a form which does not absorb irradiation in the 2600 A. region, and that absorption only occurs in injured and dead cells.

We have explored the possibility of investigating living cells by ultra-violet microscopy and have utilized for the purpose several strains of rapidly growing malignant cells which have been maintained for some years by serial transplantation in inbred strains of mice at the laboratories of the Imperial Cancer Research Fund (Ludford and Barlow[3,4]). Fibroblasts from subcutaneous connective tissue and mesothelial cells have also been included in the study. The apparatus used was that designed by Barnard, and the technique employed the same as described by him and Welch[5,6]. It has the considerable advantage in that dark-ground illumination with visual light is employed for selecting objects for ultra-violet micrography. By this procedure cells receive the minimum exposure to ultra-violet irradiation—only the few seconds during exposure of the photographic plate. A preliminary study of the cells was made by phase-contrast photomicrography so as to establish a standard for comparison with ultra-violet micrographs, in order to be able to detect any indication of cellular injury that might be revealed in the latter. It was found possible to obtain pictures of living cells by employing objectives computed for working with wave-lengths of 2570 A. and 2750 A., without any appreciable injury to cell structure. Microspectrographic analysis of living cells as carried out by Caspersson[7] with fixed tissues was not possible. Living cells would not tolerate the necessary series of exposures to irradiations of different wave-lengths. For reasons adduced by Caspersson, we have therefore assumed, without unequivocal evidence, that structures exhibiting strong absorption in micrographs taken with wave-lengths of 2570 A. and 2750 A. are of a nucleotide nature.

Numerous observations in cytopathology point to the mitochondria as sensitive indicators of cell injury. They react rapidly to ultra-violet irradiation. They first become distorted and then disintegrate, leaving vacuoles in the cytoplasm. In the sarcoma cell shown in Fig. 1 (2750 A.) are seen well-defined filamentous mitochondria characteristic of actively growing cells. The nucleus of this cell contains several large nucleolar masses with the "nucleolar associated chromatin" of Caspersson[8]. The cytoplasm contains a considerable amount of absorbing substance, which has been a conspicuous feature of all our rapidly growing malignant cells. A very pronounced change in the distribution of nucleotides takes place during cell division. About the time the nuclear membrane breaks down at prophase the mitochondria become rounded and are seen to bear peripheral deposits of nucleotides. Much smaller granules, most of which are below the limits of resolution (probably the microsomes of Claude[9]), are distinguishable among the much larger rounded mitochondria. The 'ground cytoplasm' is almost completely depleted of absorbing substance; but the chromosomes exhibit strong absorption throughout mitosis. These features are apparent in the sarcoma cell at telophase seen in Fig. 2 (2570 A.). Towards the end of the cleavage process the mitochondria become filamentous again,

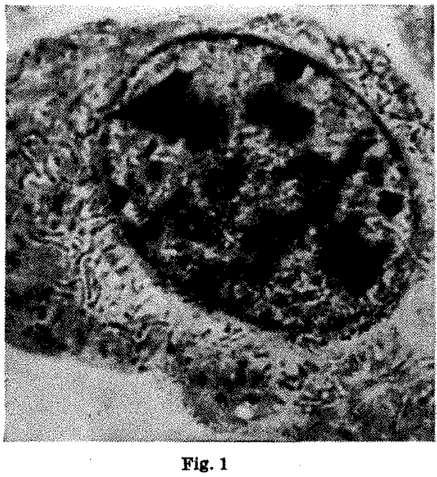

Fig. 1

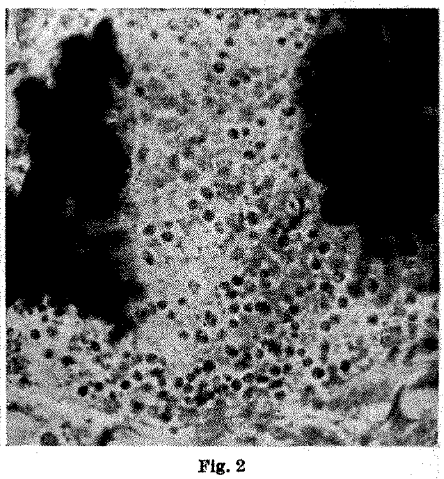

Fig. 2

Fig. 1. Living sarcoma cell with numerous filamentous mitochondria characteristic of active growth. From tumour *Rb* of the Imperial Cancer Research Fund. 2750 A.

Fig. 2. Dividing sarcoma cell from the same tumour as Fig. 1, showing the changed form of the mitochondria and altered distribution of nucleotides during mitosis. 2570 A.

and at the same time nucleotides reappear in the cytoplasm even though the chromosomes are still clearly distinguishable in the reconstituting nuclei, and no nucleoli have been reformed. In none of our micrographs of recently divided cells is there any suggestion of a greater concentration of absorbing substance directly surrounding the nuclear membrane which might imply a nuclear origin of cytoplasmic nucleoproteins. On the contrary, the nucleus is often surrounded by a relatively clear area. Our observations implicate the mitochondria rather than the nucleolus in cytoplasmic nucleoprotein synthesis.

Ultra-violet microscopy affords unique opportunities for studying the internal structure of the living nucleus. Some micrographs of dividing cells at late anaphase show the chromosomes already divided longitudinally, and this double thread-like structure persists in the 'resting' nucleus. Under appropriate conditions, nuclei can be seen to be composed of attenuated double threads upon which are disposed parallel pairs of minute granules that are not properly resolved with a wave-length of 2570 A. These would seem to be chromomeres or possibly gene loci.

Comparison of micrographs of fibroblasts from connective tissue with malignant fibroblasts (sarcoma cells) reveals a definite correlation between the amount of nucleotides and the rate of cell-growth. Particularly striking is the intense cytoplasmic absorption of rapidly growing sarcoma cells in comparison with the relatively clear cytoplasm of 'resting' fibroblasts.

Additional ultra-violet micrographs illustrating the various observations reported here will be published in subsequent communications.

Cytochemistry of the Gonadotropic Hormones

DESCRIBING the histological demonstration of mucin after periodic acid, McManus[1] states that a positive reaction is given, *inter alia*, by "certain pituitary cells" and "the colloid of the pituitary stalk". According to Chow[2], the follicle-stimulating and luteinizing fractions of the anterior pituitary secretion are glycoproteins, and Evans *et al.*[3] confirm that the former contains 10·3–13·1 per cent carbohydrate and 8 per cent glucosamine. According to K. Meyer's classification, it is thus a mucoprotein, that is, it contains more than 4 per cent hexosamine. Furthermore, Gurin[4] has shown that chorionic gonadotropin is also a mucoprotein, containing galactose (10–12 per cent) and hexosamine (5–6 per cent) as an integral part of its molecule, and Gey *et al.*[5] have demonstrated the production of this hormone by cytotrophoblast cells in tissue culture. On the contrary, Fraenkel-Conrat *et al.*[6] have shown that the growth-hormone fraction of the pituitary contains only 0·25 per cent sugar and less than 0·9 per cent glucosamine.

The technique I have used is that described by Hotchkiss[7], which is essentially like McManus' and gives positive results with a wide variety of carbohydrate substances; but of these, after ordinary aqueous fixatives, only mucopolysaccharides, mucoproteins, glycoproteins and traces of glycogen remain. If it is true that the gonadotropic hormones are produced by the basiphil cells of the pituitary, these should be stained by the McManus–Feulgen technique, with the acidophils remaining colourless.

This has been found to be the case. The colloid of the stalk, the colloid of the acini and the granules of the basiphils are stained positively. In addition, a variable proportion of the chromophobes contain vesicles and granules which are stained bright red, and these are occasionally present in mature basiphils. It is concluded (*a*) that the secretion of the basiphils is the gonadotropic hormone, and (*b*) that some chromophobes are, as Severinghaus[8] has postulated, predestined basiphils.

Similar granules are found in the Langhans' cells of the chorionic villi and of chorion epithelioma. It is suggested that these granules may be the chorionic gonadotropin.

Relative X-Ray Sensitivity of Metaphase and Interphase Chromosomes

MANY investigators have studied the problem of radio-sensitivity of cells in different stages of mitosis and meiosis in a wide range of plants and animals. Much disagreement still exists, however, as to which stages of the nuclear cycle are stages of high sensitivity to chromosome breakage and which stages are relatively resistant.

It is generally acknowledged that radio-sensitivity varies inversely with the degree of tissue differentiation, and that the change in sensitivity during differentiation is relatively high. However, it is not generally realized that the extent of sensitivity changes which may occur within a single cell-generation is also very high. A preliminary report is given here of the range of sensitivity of chromosomes to X-ray breakage during microsporogenesis in *Trillium erectum*.

Rhizomes of *Trillium erectum* were stored at 4–6° C. for several weeks before irradiation. Shortly before treatment a test slide was made from one or more anthers from each flower bud to determine the stage of division. Due to the high degree of synchronization of meiotic divisions, it may be assumed that the remaining anthers contained mostly microsporocytes in a similar stage. After exposure to 160 kV. X-rays, the plants were again placed in cold storage until microspore division, and then smears were taken.

Sensitivity was determined by counting the number of fragments present at microspore metaphase following irradiation with 50 r. at either first meiotic metaphase or early post-meiotic interphase. Examination of first or second anaphases after irradiation at first metaphase revealed very few fragments or bridges. However, after such cells had passed through post-meiotic interphase, a high degree of fragmentation was evident. (In *Trillium erectum* there is no regular interphase between first and second meiotic divisions. The chromosomes go from first anaphase directly into second metaphase without the usual resting period.)

Average number of fragments scored at microspore metaphase after a dose of 50 r. at first metaphase and at early post-meiotic interphase in *Trillium erectum*

Number of plants irradiated	Stage irradiated	Number of microspores scored	Average number of fragments per 100 pollen mother-cells
7	Metaphase I	2300	556
4	Early post-meiotic interphase	735	11·2

The average number of fragments per 100 microsporocytes (or per 400 microspores) is given in the accompanying table. The data show first metaphase to be a stage of high sensitivity to X-ray breakage, and early interphase a stage of very low sensitivity. Treatment at metaphase produced approximately fifty times as many fragments as the same dosage at early interphase. Since these two stages do not necessarily represent the stages of highest and lowest sensitivity, it is considered that a fifty-fold increase is a conservative estimate of the actual sensitivity change which occurs during the nuclear cycle. This range is considerably higher than that previously reported[1,2] for *Trillium*, mainly because the interphase had not been sufficiently studied to establish the point of lowest sensitivity. A comparable order of change has been reported by Conger[3], who found metaphase to be approximately thirty-seven times as sensitive as resting nuclei in onion root-tip cells. Failure to examine for aberrations in the succeeding divisions may be responsible for previous claims[4-6] that metaphase chromosomes are not damaged by X-rays. It should also be pointed out that measurements of sensitivity based on the percentage of rejoining of broken ends do not agree with a sensitivity value based on fragmentation only[7]. This also may have contributed to conflicting claims[8] as to stages of high *versus* low radio-sensitivity.

This investigation was begun in the Biological Laboratories of Harvard University. Financial assistance was received from the American Cancer Society and from the Cancer Research Division of the Donnor Foundation.

Production of *i*-Erythritol by *Aspergillus niger*

CERTAIN strains of *A. niger*, as is well known, ferment sugar to citric acid to the virtual exclusion of any other acid. Strong citric acid fermentations, however, are often accompanied by the production of mould starch[1] and a dextrin-like substance[2]. The present communication directs attention to the formation also of *i*-erythritol. Though this tetrahydric alcohol has already been found in two species of *Penicillium*, namely, *P. brevi-compactum* Dierckx and *P. cyclopium* Westling[3], and in one species of *Aspergillus*, *A. terreus*[4], rather surprisingly no one has hitherto reported its occurrence in cultures of *A. niger*.

The citric acid of the fermented solution and washings from the mould mycelium is first precipitated as the calcium salt and removed by filtration. The filtrate, which may contain some residual reducing sugar in addition to the starch and dextrin, is concentrated by evaporation. During this operation, most of the calcium citrate still in solution is thrown out and is filtered off. The filtrate is treated with two or three volumes of alcohol and the precipitate which forms is removed. The alcohol is evaporated off and the syrup remaining crystallizes on standing. The crude crystals are separated and purified by treatment with decolorizing carbon and recrystallization.

The aqueous solution of these crystals is neutral, shows no optical activity and does not reduce Fehling's solution. It has a sweet taste. Solubility in water rises rapidly with increasing temperature.

The crystalline substance gave m.p. 119·5–120·5° C.; mixed with a sample of authentic *i*-erythritol, m.p. was 119–120° C. Analysis:— found (Weiler); C, 39·57; H, 8·24 per cent; calculated for $C_4H_{10}O_4$: C, 39·34; H, 8·25 per cent. The acetyl derivative had m.p. 85–86° C.

I desire to acknowledge the assistance of two colleagues, Mr. G. H. Gossop and Mr. L. G. Manchester, in the work here reported.

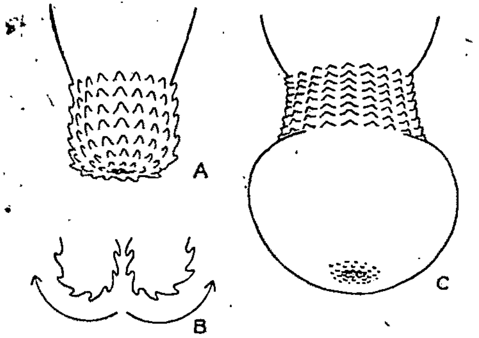
Thixotropy, and the Mechanics of Burrowing in the Lugworm (*Arenicola marina* L.)

Chapman and Newell[1] have recently published the following argument:

(1) Lugworms can burrow into a particular beach whether covered by sea-water or not. The total downward thrust which a worm can exert is limited by its weight. If one divides the immersed weight of a worm by the area of its front end, one finds "that the maximum pressure which can theoretically be exerted cannot exceed 16 g./sq. cm.". (2) A man can walk across the same beach without sinking in, though his feet exert a pressure of about 150 gm./sq. cm. (3) "The explanation of this apparent anomaly must be sought in the physical properties of the wet sand." The authors demonstrate that the sand is thixotropic by "stepping five times with the weight of the body on the foot"; this causes the

sand to liquefy, after which it fairly rapidly sets again. They suggest that "when a worm begins to burrow in the sand, its resistance is first reduced by alternating extrusion and withdrawal of the proboscis and then the anterior end of the worm is thrust into the softened sand".

It will be noted that the demonstration of thixotropy was made by using pressures considerably greater than those the lugworm can produce. But, in any event, I am unable to see any real contradiction between the first two observations, and do not believe that it is necessary to invoke thixotropy at all.



Action of the proboscis. *A*, Incomplete extrusion of the buccal mass. *B*, Section through the advancing buccal mass. *C*, Extrusion of the pharynx

As the worm burrows, it repeatedly extrudes and withdraws its proboscis. This proboscis consists of two main parts. The first part to emerge is the buccal mass, which is set with strong, conical teeth, directed as shown in the diagram (*A*). As it comes out, the thrust on the sand will first be sideways to the line of advance, then backwards towards the animal's tail, as shown by the arrows in (*B*). The latter (backwards) thrust is assisted by 'flanging' movements of the more anterior chætigerous annuli[2], which occur during burrowing. If one causes a worm to burrow into an artificial sand consisting of very small glass spheres (Messrs. Chance Bros.' 'Ballotini') —which it can and sometimes will do—then these movements of the chætigerous annuli may be seen.

After its extrusion, the buccal mass shortens considerably as the second part of the proboscis, the pharynx, is violently thrown out (*C*). The pharynx is a soft balloon, with numerous very small papillæ. Its ejection rather suggests the sudden blowing of a bubble by the worm. It may serve to drive out the sand from the hole rasped by the buccal mass, and perhaps to shape it.

The front end of the worm narrows and lengthens as the buccal mass is extruded, as if to drive it further into the sand. In the second stage, when the buccal mass shortens and widens, the front end of the worm does so too; so the pharynx is thrust out more or less into the area already worked upon by the buccal mass.

These facts show that the lugworm is not at all comparable to a body sinking into the sand under its own weight. It is more like a digging rabbit, which scratches and shovels the earth away. The actual disruption of the structure of the sand must be done by the teeth of the emerging buccal mass. Unhappily, it is not easy to assess the force with which the worm could make them diverge from each other. Chapman and Newell[1] give a number of valuable data on the hydrostatic pressure in the body cavity under various conditions; they recorded pressures up to 27 cm. of sea-water in worms "actually engaged in burrowing". But other factors play a part; if one transects a worm immediately behind the first chætigerous annulus, the very small front end so isolated can still extrude and withdraw its buccal mass, though it seems unable to throw out its pharynx.

Some Geometrical Considerations Regarding Imbricate Æstivation

IN connexion with some anatomical investigations now in progress, an occasion has arisen for reviewing the evidence for a possible affinity between the Ranales and the monocotyledons. A critical consideration of certain floral features reveals that a number of phenomena on which considerable stress has been placed are not, in fact, independent results, but may be deduced as geometrically inevitable consequences of the nature of imbricate æstivation.

Imbricate æstivation may be defined as the arrangement of flattened organs in a ring so that each edge of each member of the ring overlaps with one of the edges of an adjacent member. It will be convenient to distinguish three types of member: external, with both edges outside those with which they overlap; internal, with both edges inside; and oblique, with one edge inside and one edge outside. Let the numbers of members in each category be denoted by e, i and o respectively. Then the total number of outside edges is $2e + o$ and the total number of inside edges is $2i + o$. But, from the nature of imbricate æstivation, there are as many outside edges in a ring as inside ones, so that $2e + o = 2i + o$ and $e = i$. There follow two important corollaries: first, the number of oblique members is odd or even according as the total number of members in the ring is odd or even; secondly, a ring with an odd number of members must have at least one oblique member.

Now suppose that a ring is being built up by placing members in position one at a time. If the first member is to be external, the one next to it cannot be external. It can be either internal or oblique. If it is oblique its free edge (that is, the one farthest from the first member) will be an outside edge. The third member can then be either internal or oblique, but not external. Obviously, it is impossible, moving round the ring from an external member, to reach another external member without first passing an internal one. A similar train of argument can be used to prove the converse. We have therefore established the proposition that: the internal and external members of any ring of imbricating organs will occur in equal numbers and will alternate regularly all round the circumference.

In other words, any ring of imbricating organs may be regarded as consisting of two equal alternating whorls, with the addition of a varying number of oblique members which do not belong definitely to either whorl, and which may be distributed in various ways. The appearance of two independent alternating whorls can be regarded as the special case arising when o is zero; and contort æstivation as that arising when e and i are zero.

Consider a ring of organs in which the position of any edge (that is, whether inside or outside) is independent of the position of the other edge of the same member. Clearly, it is to be expected that, of the total number of members present, one quarter will be external, half oblique and the remaining quarter internal.

It is interesting to reconsider some of the observed facts in the light of these theoretical results. The commonest number of petals in *Ficaria verna* is eight, as stated by Salisbury[1]. In most cases this number is made up of three internal petals, three external and two oblique. Obviously the position of one edge of a petal markedly influences that of the other edge; conditions are unfavourable for the production of oblique members. Salisbury concluded that the corolla was derived from one with two alternating trimerous whorls, the oblique members having arisen by division of the members of these whorls. But it is not difficult to find flowers in which the 'whorls' are dimerous, while in flowers with more than eight petals there are often four external and four internal petals.

Hitherto, it has not been sufficiently appreciated that any condition unfavourable to the production of oblique members automatically brings about the appearance of alternating whorls. In *Ficaria* the elimination of oblique members is incomplete, but has gone far enough to give, in most flowers, an appearance of alternating trimerous whorls.

It has been shown that complete elimination of oblique members is not possible when the total number of organs is odd. The pentamerous plan does not permit elimination of oblique members beyond the condition seen in the familiar quincuncial arrangement. The observation (ref. 1, p. 54) that, in plants with variable numbers a hexamerous calyx or corolla may consist of two trimerous whorls while a pentamerous one is quincuncial, is therefore only to be expected, and does not justify the conclusion that the oblique member in the quincuncial arrangement is the result of the fusion of one external member with one of the internal ones.

It is not my purpose to belittle the significance of evidences of trimery in the Ranalean flower, or to deny the conclusions reached by Salisbury and others as to increase or decrease in the number of floral parts, but merely to point out that peculiarities of æstivation are often only expressions of geometrical necessity, and are therefore not available as evidence for determining the course of floral evolution.

Initiation of Explosions by Grit Particles

EARLIER work[1,2] has shown that the initiation of liquid and solid explosives by impact or friction is due to the formation of localized hot spots. These hot spots may be generated by adiabatic compression of small entrapped bubbles, by friction and shear at solid surfaces, and, in extreme cases, by the viscous heating of rapidly flowing explosive. It was found that for nitroglycerine the minimum temperature of the momentary hot spot necessary for initiation by friction was *c.* 400–500° C.

It is known that explosives are made more sensitive both to impact[3] and to friction[1] if small particles of grit are mixed with them. The early work showed that the rise in the surface temperature of a solid under friction is usually limited by its melting point. If initiation is due to the development of hot spots on the grit particles, we should therefore expect that the effectiveness of a particle would depend on its melting point. Some experiments have been carried out to investigate this.

A few small solid particles of known melting point were added to the solid explosive, which was spread as a thin layer between flat steel surfaces. In one series of experiments the explosive was then subjected to rapid shear, while in another series it was subjected to an impact just strong enough to give very occasional explosions (*c.* 2 per cent) in the absence of any grit. Over the range used the hardness of the particle was relatively unimportant, but its effectiveness in initiating an explosion depended on its melting point.

Initiation of P.E.T.N. in the presence of foreign particles

'Grit' added	Hardness (Moh scale)	Melting point (° C.)	Explosion efficiency % (friction)	Explosion efficiency % (impact)
No grit	—	—	0	2
Ammonium nitrate	2–3	169·6	0	~2·5
Potassium hydrogen sulphate	3	210	0	~2·5
Silver nitrate	2–3	212	0	2
Sodium dichromate	2–3	320	0	0
Sodium acetate	1·5	324	0	0
Potassium nitrate	2–3	334	0	0
Potassium dichromate	2–3	398	0	0
Silver bromide	2–3	434	50	6
Lead chloride	2–3	501	60	27
Silver iodide	2–3	550	100	—
Borax	3–4	560	100	30
Bismuthinite	2–2·5	685	100	42
Glass	7	800	100	100
Chalcocite	3–3·5	1100	100	50
Galena	2·5–2·7	1114	100	60
Calcite	3	1339	100	43

The hardness of P.E.T.N. is *c.* 1·8 and its melting point 141° C.

The friction experiments gave the results with P.E.T.N. shown in the fourth column of the accompanying table. All the substances melting above 430° C. were effective in initiating this explosive, while all those melting below 400° C. had no effect. Similar results were obtained for the frictional initiation of lead azide, but in this case the limiting temperature was somewhat higher. Silver iodide melting at 550° C. and all substances of higher melting point were effective, but lead chloride, melting point 501° C., and lower melting solids were not.

The last column of the table shows the impact sensitivity of P.E.T.N. under similar conditions, and again it will be seen that only substances melting above 430° C. were effective. Impact experiments on lead styphnate and mercury fulminate gave similar results, but the limiting melting point was about 500° C.

High-speed camera studies confirm that initiation occurs at the grit particle, and that the first stage of propagation is usually a slow burning[4]. These simple experiments indicate that the initiation of explosives containing grit is due to the formation of hot spots on the grit particle. Under the conditions of these experiments, the minimum effective hot-spot temperature for the explosives studied was again about 400–500° C.

We thank the Ministry of Supply (Air) and the Royal Society for grants for equipment, and Imperial Chemical Industries, Ltd. (Explosives Division), for the research maintenance of one of us (O. A. G.).

Note added in proof (*October* 8). Recently, Ubbelohde *et al.*[5] have published results on the effect of grit. Under the conditions of their experiments they did not observe an increase in sensitivity unless the hardness of the grit exceeded 4 on the Moh scale. They find supporting evidence for hot spot initiation in that the sensitivity with hard grit particles is influenced by the melting point of the anvil.

Dielectric Properties of Mixed Barium and Strontium Titanates at 10,000 Mc./s.

Measurements have been made of the complex permittivity ($\kappa' - j\kappa''$) of a series of mixed barium and strontium titanates at 9,450 Mc./s. and 20° C. by a technique, already described[1,2], which employs a wave-guide containing a multilayer dielectric slab.

The variation of κ' and $\tan\delta$ ($= \kappa''/\kappa'$) at 9,450 Mc./s. is shown in Fig. 1, and also that of κ' at 1·5 Mc./s., for purposes of comparison. The value of $\tan\delta$ at 1·5 Mc./s. is of the order 0·01 throughout.

It is well known that the addition of strontium titanate to barium titanate lowers the temperature of the Curie point by an amount proportional to the percentage of strontium[3]. The Curie point occurs at 20° C. for the composition 72 per cent $BaTiO_3$, 28 per cent $SrTiO_3$. The marked variation in permittivity which occurs at 1·5 Mc./s. for 72 per cent $BaTiO_3$ is considerably modified at 9,450 Mc./s. and results for the compositions 66 and 75 per cent $BaTiO_3$, lying closely on either side of this point, suggest that there is no great perturbation in the dielectric properties, although this has not been closely investigated. The dispersion in permittivity suddenly becomes appreciable, and the loss tangent rises rapidly for concentrations of barium titanate well below that at which the material becomes permanently polarized.

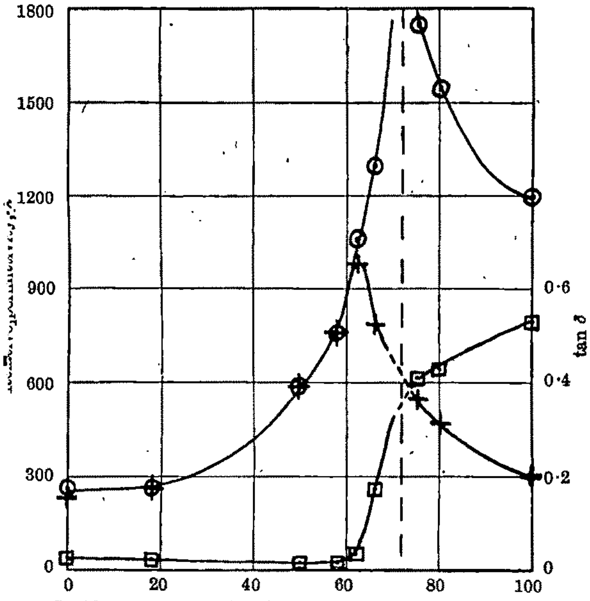

Fig. 1. Barium-strontium titanate mixtures at 20° C. ⊙, κ' at 1·5 Mc./sec.; +, κ' at 9,450 Mc./sec.; □, $\tan\delta$ at 9,450 Mc./sec.

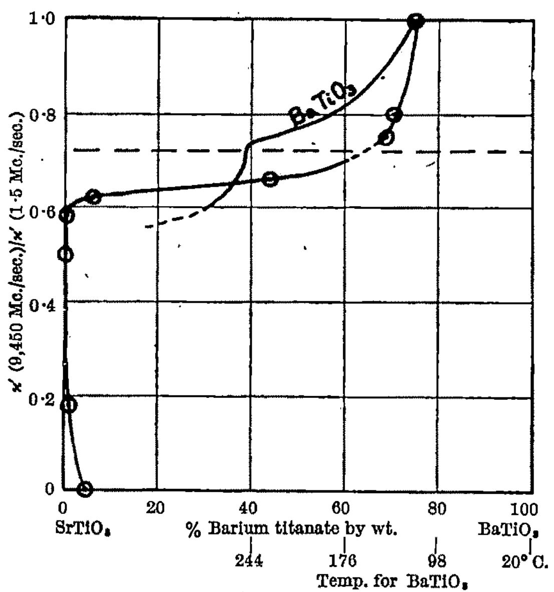

Fig. 2

An alternative way of showing the dispersion is to plot $\frac{\kappa' \text{ (at 9,450 Mc./s.)}}{\kappa' \text{(at 1·5 Mc./s.)}}$ versus composition as in Fig. 2.

On the same figure is plotted the result for barium titanate alone, at variable temperature[2], where the temperature scale is related to the composition of the mixed titanate by the shift in the Curie point mentioned above. The essential similarity of the two curves may be noted, and also the fact that in both cases the dispersion is closely associated with the permanently polarized condition.

Incidentally, the material with composition 56 per cent $BaTiO_3$ 44 per cent $SrTiO_3$ having $\kappa' = 760$ and $\tan\delta = 0·02$ at 9,450 Mc./s. and 20° C. should be of considerable technical importance in microwave work. The maximum permittivity value observed was 990 with $\tan\delta = 0·04$ at a composition of 62 per cent $BaTiO_3$ 38 per cent $SrTiO_3$.

I wish to thank Mr. Popper, of Philips Electrical, Ltd., for providing suitable ceramic materials.

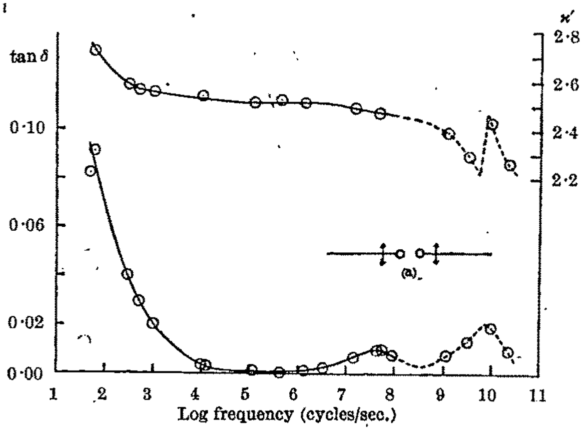
Dielectric Behaviour of Methyl Palmitate: Evidence of Resonance Absorption

THE complex permittivity $\varkappa = \varkappa' - j\varkappa''$ of methyl palmitate, $C_{15}H_{31}COO.CH_3$ (melting point (sharp) 29·7° C.), has been determined at room temperature (17–20° C.) over the frequency-range 50–3 × 10^{10} cycles/sec., with the results shown in the diagram, in which $\varkappa''$ is presented in terms of the tangent of the dielectric loss angle, $\tan \delta = \varkappa''/\varkappa'$. The 50–$10^4$ c./s. measurements were made on a Schering bridge; the 10^4–10^8 c./s. ones by a reactance variation resonance method[1], and the higher-frequency measurements by use of a number of cavity resonators[2].



The results reveal three absorption regions in the spectrum investigated, and in seeking an explanation of the mechanism of these the following possibilities must be considered: normal (D.C.) conduction; anomalous conduction arising from the presence of aggregations of conducting impurity; dipole relaxation; and the occurrence in this frequency-range of a natural vibration frequency of the dipolar molecules or of parts of these molecules. The measured D.C. conductivity was found to account for no more than 1 per cent of the low-frequency value of $\tan \delta$, and the material tested was of such purity as to exclude the second possibility. In connexion with the third, if there exist two positions of equilibrium corresponding to opposite dipole directions with a transition probability of p per sec., then energy absorption will occur around the frequency $p/2\pi$ c./s. With methyl palmitate there appear to be two such possibilities, involving rotation of the molecule about its axis and about an axis perpendicular to this. Since the probability of the latter type of rotation would seem to be small, the absorption between 50 and 10^3 c./s. may perhaps be accounted for on this basis. Unfortunately, in the absence of measurements at still lower frequency, the peak of this absorption is undetermined; but there is reasonable correlation between the observed changes of $\varkappa'$ and $\tan \delta$ in this region, and they indicate an effective resolved component of dipole moment of the order of 1·3 Debye units.

On this basis the second absorption is presumably due to a rotation of the molecule about its axis, though, since it has been concluded by Malkin[3] from X-ray studies that methyl esters crystallize as double (end-on) molecules, the moving unit may be the double molecule. It can be estimated from the variation of $\tan \delta$ in the region of this second absorption that $\varkappa'$ should decrease by 0·06, which is consistent with the observed variation of $\varkappa'$, and suggests an effective resolved part of the dipole moment, in this case, of about 0·4 Debye units.

The variation of $\varkappa'$ associated with the third, ultra high-frequency, absorption region would seem to identify this as a resonance phenomenon; although, if a curve be drawn through the four available experimental points, this variation appears as the inverse with respect to frequency of what is to be expected. This suggests that the four points at which measurements have thus far been made are inadequate to afford full resolution of the dispersion and absorption, and measurements at additional frequencies and at low temperatures are essential for clarification.

A resonance absorption in solids in the electrical spectrum has not previously been reported; but the prospect of this occurrence with compounds of the type under consideration within the 1/10 to 1/100 cm. wave-length band (3 × 10^{11} – 3 × 10^{12} c./s.) has been predicted by Fröhlich[4]. The evidence that methyl esters crystallize in double molecules suggests, as one possibility, that the resonance may be due to oscillation of the component single molecules about an axis perpendicular to their length, in the manner indicated at (*a*) in the diagram. If this be so, the frequency of vibration would presumably be lower than for the type of oscillation discussed by Fröhlich.

It is desired to emphasize the tentative nature of the explanations suggested above pending the completion of further work now in progress.

Our thanks are due to Dr. L. Hartshorn, of the National Physical Laboratory, for help in connexion with the low-frequency measurements, and of one of us for a studentship provided by the Australian Council for Scientific and Industrial Research.

Velocity of Sound in Free Air

A PREVIOUS communication[1] described an oscillographic method for measuring the velocity of sound in air. Further experiments have been made during the past four years, with the aid of a grant from the Research Committee of King's College, Newcastle-upon-Tyne, and during 1947 a series of 940 determinations was made in the Bute Hall of the University of Glasgow.

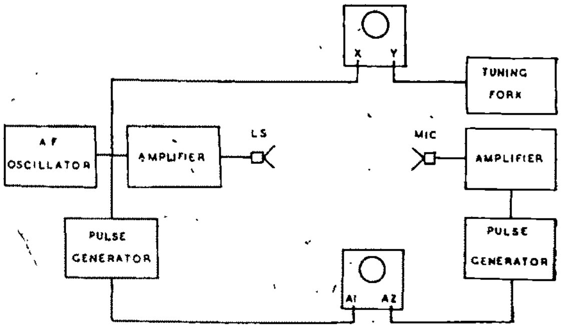

Fig. 1. General arrangement of apparatus

The object of these experiments was to measure the velocity of sound in free air with an accuracy of the same order as that which has been achieved in the best supersonic measurements. The general arrangement of the apparatus is shown in Fig. 1. Sound, at 13,500 c./s., was emitted by a small moving-coil loud speaker connected through an amplifier to an audio-frequency oscillator, and was detected by a receiver, consisting of another loud speaker, identical with the first, mounted on a screw mechanism, permitting it to be moved relative to the source, along the line joining their centres. The output from the receiver was amplified and passed to a pulse-generating circuit, which delivered a train of pulses, each about a microsecond in duration. These pulses were used to deflect one beam of a double-beam oscillograph, which had an internal time-base, synchronized by the audio-frequency oscillator output.

If the microphone was moved relative to the source, the pulses travelled across the screen, and the distance between two successive positions of the microphone at which a pulse coincided with an arbitrary reference mark on the screen was equal to the wave-length of the sound. The reference mark was obtained by connecting the audio-frequency oscillator to a pulse-generating circuit, and applying the resulting pulses to the other beam of the oscillograph.

At a frequency of 13,500 c./s., the wave-length of sound at normal temperatures is about one inch. The screw was six feet long and was fitted with a scale calibrated in thousandths of an inch. By moving the microphone, simultaneously observing the oscillograph screen through a telescope, and counting the transits of the receiver pulses, a length equal to 40 wave-lengths was measured 940 times, under varying atmospheric conditions. The frequency of the oscillator was checked continuously against that of a 1,000 c./s. valve-maintained tuning fork (which had an accuracy of a few parts in a million), using a Lissajous figure on the screen of a subsidiary oscillograph; after the apparatus had been operating continuously for a fortnight, the frequency drift was very small and could easily be corrected. The temperature was found by observation (through a telescope several yards away) of two mercury thermometers suspended between the source and the receiver. The humidity of the air was found from readings with a whirling hygrometer, and the carbon dioxide content was measured with a Haldane carbon dioxide apparatus. The room in which the experiments were conducted was 115 ft. long, 69 ft. wide and 67 ft. high; it was empty of furniture and was free from serious draughts. The apparatus was placed in the centre of the room, well clear of the floor, and no reflexions from walls or ceiling were detected.

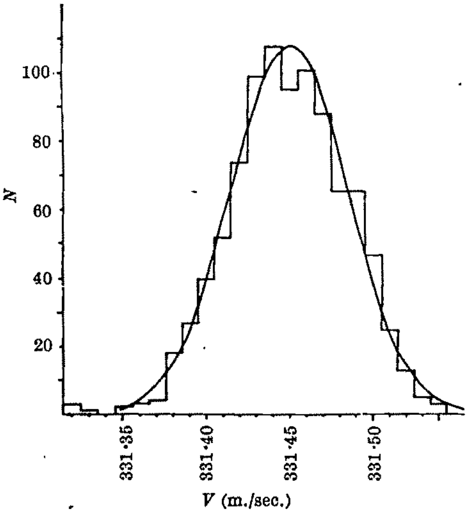

Fig. 2. Distribution of the 940 results, with normal error curve superimposed

Corrections were applied to the results for the influence of the following factors: (1) temperature, which affects (*a*) the density, (*b*) the specific heat C_v, and (*c*) the imperfection of the air; (2) presence of water vapour, which affects (*a*) the density and (*b*) the specific heat C_v of the air; (3) the known error of the screw and the thermometer.

The mean value found for the velocity of sound at a frequency of 13,500 c./s. in dry air at temperature 273·16° K. and pressure 1013·2 mb., containing 0·03 per cent of carbon dioxide, was 331·45 ± 0·04 metres per second. The distribution of the 940 results is shown in Fig. 2, with the normal error curve for the same number of results and the same standard deviation superimposed for comparison.

A fuller account of this work is being prepared for publication elsewhere.

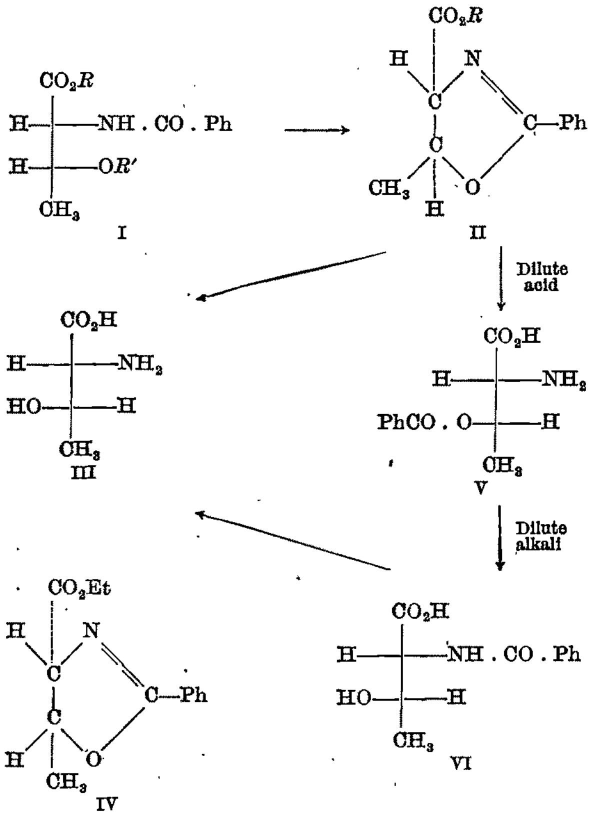
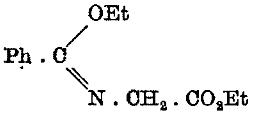
Studies in the Synthesis and Isolation of Threonine

IN a communication to the editor of the *Journal of the American Chemical Society*[1] which has just been received are described the conversion of DL-N-benzoyl*allo*threonine methyl ester (I, R = Me; R' = H) into the corresponding oxazoline (II, R=Me) by the action of thionyl chloride and hydrolysis of the oxazoline with acid to give DL-threonine (III). This discovery was anticipated by Attenburrow, Elliott and Penny[2], who described not only the thionyl chloride method of inverting the configuration of DL-N-benzoyl*allo*threonine ethyl ester (I, R=Et; R'=H), but also a second and closely related method consisting of the treatment of the *p*-toluenesulphonyl derivative (I, R=Et; R'=Ts) with potassium acetate in boiling alcohol, followed by acid hydrolysis. The same oxazoline (II, R=Et) was produced in both cases, and the view was advanced that inversion of configuration took place simultaneously with ring closure. The *trans* structure was therefore assigned to the oxazoline on the basis of the known configuration of threonine[3].

It has now been found that the reaction of DL-threonine ethyl ester hydrochloride with benzimido-ethyl ether constitutes a third method of preparing the oxazoline (II, R=Et). In this type of reaction, which was first applied by Barber *et al.*[4] to ethanolamine, the configuration of the threonine molecule is retained. In a similar way the *cis*-oxazoline (IV), which yielded pure DL-*allo*threonine on acid hydrolysis, was prepared from DL-*allo*threonine ethyl ester hydrochloride. The *cis*-oxazoline, when boiled with aqueous alkali, was rapidly converted into the *trans* form with simultaneous hydrolysis of the ester group. The resulting *trans*-2-phenyl-5-methyl-Δ^2-oxazoline-carboxylic acid (II, R=H) was also obtained by hydrolysis of the *trans*-oxazoline ester (II, R=Et) in the same way. This interconversion, which must be the result of an equilibrium reaction favourable to the *trans* form, probably occurs via the anion of the oxazoline ester. The *trans* structure was assigned to the carboxylic acid because it was converted successively into DL-O-benzoylthreonine (V) and DL-N-benzoylthreonine (VI) by the action of dilute acid and alkali respectively. It seemed scarcely possible that any configurational changes could occur in these reactions.





VII

As a result of these discoveries, the separation of stereoisomers described in an earlier synthesis of DL-threonine[2] has been rendered unnecessary. Crude DL-ethyl-α-benzamido-β-hydroxybutyrate, an intermediate product in the synthesis, was converted into a mixture of the oxazolines II and IV by the action of thionyl chloride and then into pure DL-N-benzoylthreonine by the series of changes already described. The overall yield was about 60 per cent. Details of this work have already been submitted for publication in the *Journal of the Chemical Society*. It follows from these experiments that the interconversion of D- and L-threonine should be readily achieved, and this is being investigated.

The reaction of benzimidoethyl ether with threonine ethyl ester hydrochloride has been used for the isolation of threonine from casein. Commercial casein was hydrolysed with hydrochloric acid, and after removal of the glutamic acid and the basic amino-acids the remaining mixture was esterified and subjected to the action of benzimidoethyl ether. It was known that glycine ethyl ester hydrochloride would be converted into the derivative (VII) by this reaction[5] and also that compounds of this type, when treated with alkali, would be converted into the corresponding acylamino-acids[6]. It was assumed that other monoamino-acids would behave similarly.

The product was hydrolysed with alkali and acidified to *p*H 1. The acid-insoluble N-benzoyl compounds were removed by extraction, leaving in solution only the acid-soluble O-benzoyl derivatives of serine and threonine. These were converted into the N-benzoyl derivatives when the solution was again made alkaline. As was expected from stereochemical considerations, the N-benzoylserine was racemic. It was separated from the L-N-benzoylthreonine in a pure condition as the sparingly soluble β-phenylethylamine salt. The L-N-benzoylthreonine remaining in the mother liquors as a soluble salt was purified as the free acid by counter-current distribution between ether and water. The yield of L-N-benzoylthreonine was about 10 per cent of that to be expected from the threonine content of the casein hydrolysate.

Experiments are being continued and will be published in full at a later date.

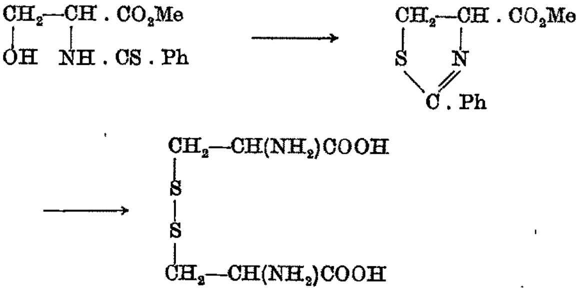
Conversion of DL-Serine into Inactive Cystine

In a previous paper[1] it was shown that DL-N-benzoyl*allo*threonine ethyl ester was converted into the corresponding oxazoline ester with inversion of configuration at the β-carbon atom by the action of thionyl chloride.

This reaction has now been used for the replacement of the hydroxyl group in serine by a thiol group. DL-Serine methyl ester hydrochloride was converted into DL-N-thiobenzoylserine methyl ester by the method of Holmberg[2]. The latter substance, on treatment with thionyl chloride, afforded the corresponding thiazoline in almost quantitative yield. Hydrolysis of the thiazoline and oxidation of the product gave inactive cystine in good yield. Similar reactions have



been carried out on DL-*allo*threonine ethyl ester hydrochloride.

These investigations are being continued.

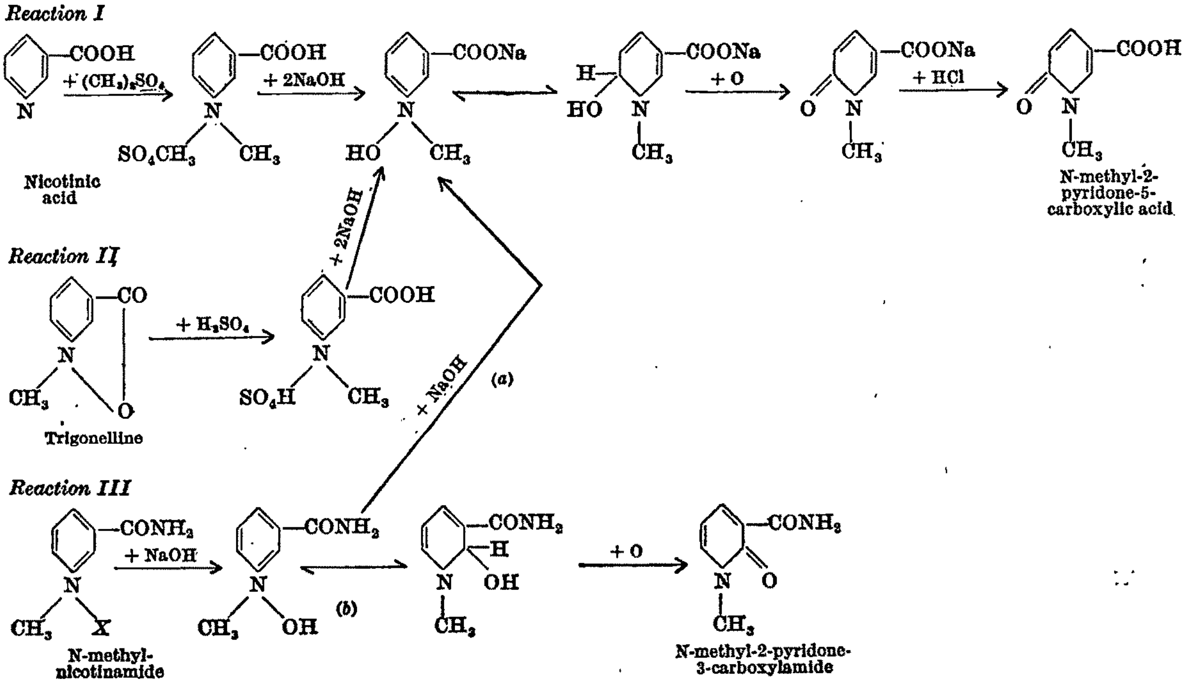
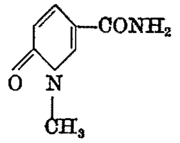
Synthesis of Derivatives of N-Methyl-2-Pyridone from Nicotinic Acid and Nicotinamide

IT is well known that N-methylnicotinamide is formed from nicotinamide by methylation in the human body, and Knox and Grossman[1,2] have shown that N-methylnicotinamide is itself capable of being metabolized. These workers not only demonstrated that N-methylnicotinamide could be oxidized to N-methyl-2-pyridone-5-carboxylamide by an enzyme present in rabbit liver; but they also succeeded in isolating the latter compound from human urine after the ingestion of doses of 0·6–0·9 gm. of nicotinamide per day.

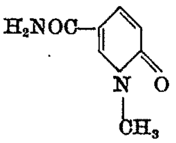
Knox and Grossman described the compound as 1-methyl-3-carboxylamide-6-pyridone, and the corresponding acid as 1-methyl-3-carboxy-6-pyridone. Their nomenclature is similar to that adopted by Beilstein (1-methyl-6-pyridone-3-carboxylic acid), but differs from that used by the earlier workers in this field[3-6], who invariably used the name N-methyl-2-pyridone-5-carboxylic acid.



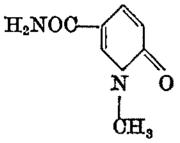
Both names are acceptable, but we prefer to regard the compound as N-methyl-2-pyridone-5-carboxylamide, not only because the earlier workers used this nomenclature, but also because it seems to us to show more clearly the relationship of the compound, from the point of view of chemical structure, to the isomeric N-methyl-2-pyridone-3-carboxylamide (see later). No confusion exists in the literature as to the nomenclature of the latter compound.



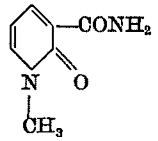
1-methyl-3-carboxylamide-6-pyridone



N-methyl-2-pyridone-5-carboxylamide



N-methyl-2-pyridone-5-carboxylamide



N-methyl-2-pyridone-3-carboxylamide

We have studied[7] the reactions which occur *in vitro* when nicotinamide or nicotinic acid is methylated and is then oxidized by the method of Decker[8,9]. It was found that nicotinic acid gave N-methyl-2-pyridone-5-carboxylic acid after methylation and oxidation, but that nicotinamide gave the amide of the isomeric acid, namely, N-methyl-2-pyridone-3-carboxylic acid. These results provided the first evidence that the course of the Decker conversion may be influenced by the nature of the substituent in the 3-position. They also indicated either that the methylation and oxidation of nicotinamide follows a different course *in vitro* from that *in vivo*, or that nicotinamide is converted to nicotinic acid before being methylated and oxidized in the animal body.

After this work was completed, a recent paper of Huff[10] came to our notice, in which he described the preparation of N-methyl-2-pyridone-5-carboxylic acid by the oxidation of either trigonelline acid sulphate or N-methylnicotinamide. Since Huff provided no explanation for the reactions which occurred, and since his results might appear to conflict with our findings, it seemed desirable that the position should be clarified. His findings and our own have therefore been combined in the accompanying diagram.

The methylation of nicotinic acid with dimethyl sulphate and the oxidation of the methylation product with alkaline ferricyanide by our method proceeds according to reaction I. The preparation of trigonelline acid sulphate from trigonelline and its oxidation with alkaline ferricyanide, as described by Huff, is shown in reaction II. It is clear that these reactions are very similar. In both cases there is a free carboxylic acid group in the 3-position before oxidation occurs.

The oxidation of N-methylnicotinamide is shown in reaction III. Since the amide group in the 3-position can be easily removed by saponification, the reaction can follow two courses (*a* and *b*). If N-methylnicotinamide is oxidized by our method, saponification does not occur, since a low temperature is maintained and the alkali and ferricyanide are added simultaneously. Only N-methyl-2-pyridone-3-carboxylamide is formed (reaction III *b*), which may be isolated by repeated extractions with chloroform. In the method of Huff, however, the alkali is added at room temperature, and before the ferricyanide. In this case reaction III *a* also occurs. Huff isolated only N-methyl-2-pyridone-5-carboxylic acid from the reaction mixture, and did not attempt to isolate N-methyl-2-pyridone-3-carboxylamide.

The following experiment confirms our previous results and clarifies those of Huff. Two 10-gm. portions of N-methylnicotinamide iodide were oxidized side by side, one according to our procedure and the other by a method similar to that of Huff. In the latter case the alkali was added to the solution of N-methylnicotinamide at room temperature, and the ferricyanide was added half an hour later. In both cases N-methyl-2-pyridone-3-carboxylamide was isolated from the reaction mixture; but the yield was greater by our method. No trace of N-methyl-2-pyridone-5-carboxylic acid could be found in the mother liquor when the oxidation was arranged to take place as described by us; but, when Huff's method was used, 0·5 gm. of crude N-methyl-2-pyridone-5-carboxylic acid was obtained. After further purification, by crystallization from water, the melting point was 238°, which agrees well with the value of 237–238° reported by von Pechmann and Welsh[5].

It is clear that only in method III *b* is the amide group present in the 3-position before oxidation, and that only in this case is the 2,3-isomer formed. It is also apparent that the method of Huff for the preparation of N-methyl-2-pyridone-5-carboxylic acid from N-methylnicotinamide represents a side-reaction, and does not indicate the true course of the oxidation of N-methylnicotinamide *in vitro*.

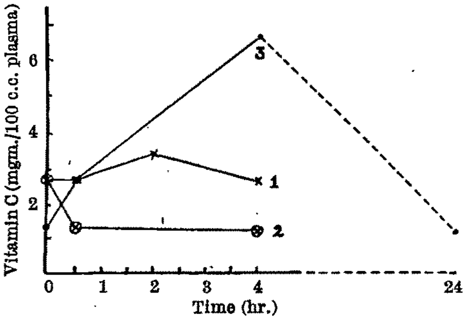
Species Difference in the Biosynthesis of Vitamin C and Response to Diabetogenic Substances

Tidwell and Axelrod[1] have recently confirmed the views of Nath and Brahmachari[2] regarding the initial stimulation of islet cells and excess production of internal insulin in the experimental animals by injection of intermediary fat metabolites, especially sodium aceto-acetate. Their findings that the condition of hyperglycæmia cannot be developed in rats even after the injection of sodium aceto-acetate for 28 days (daily dose 18 mgm. per 100 gm. body-weight) also confirm the recent findings of Nath and Brahmachari[3], who observed a 50 per cent increase in the potency of the pancreatic insulin of the treated guinea pigs in about twenty-five days, and a marked decrease in the activity of internal insulin only on prolonged injection for about seventy days.

In their three-day injection experiments, however, Tidwell and Axelrod observed that rats are far less susceptible to the action of aceto-acetate, especially towards the degree of increase in blood sugar, than the rabbits used by Nath and Brahmachari[2], and they (Tidwell and Axelrod) have pointed out that species difference might play an important part in the response to diabetogenic substances. Thus, though alloxan is known to cause marked diabetogenic effect on rats, Scott *et al.*[4] find little evidence of injury produced by it in islet cells in various species of birds, while Ruben and Yardumian[5] have shown that mere enteric absorption of alloxan is quite sufficient to injure the β-cells of the islets of rabbits.

Attempts were therefore made to see if such difference in behaviour could be accounted for through differences in the capacity for immediate biosynthesis of vitamin C, which is known to be highly beneficial in improving carbohydrate tolerance of diabetics[6]. Mosonyi[7] has shown that animals which produce ascorbic acid react to the administration of chemicals, especially of some ketones, by increasing the ascorbic acid excretion; though chloroform was ineffective in causing increase in the biosynthesis of vitamin C in rats, chloreton, a condensation product of acetone and chloroform, has been found by Ghosh[8] to exert great influence in the process.

In order to investigate the degree of biosynthesis in different animals (rats and rabbits) by means of a sudden shock caused through the injection of some intermediary fat metabolites, the following experiment was undertaken. Sodium aceto-acetate in the dose of 18 mgm. per 100 gm. body-weight was injected intramuscularly into some groups of animals



Curve 1 : rabbits, 6 mgm. sodium aceto-acetate per 100 gm. body wt.
,, 2 : ,, 18 ,, ,, ,, ,,
,, 3 : rats, ,, ,, ,, ,,

of each kind, and the quantity of vitamin C in 100 c.c. of plasma was estimated colorimetrically (by means of a photo-electric colorimeter) according to the usual method with the indophenol dye. The results of the preliminary observation are represented graphically.

This figure shows that the rabbits are unable to adjust themselves with the biosynthesis of their high requirements of vitamin C in order to cope with the situation, but that rats can go on synthesizing it even with such a high dose of the keto compound. 6 mgm. of the keto acid per 100 gm. of the body-weight (that is, one-third of the previous dose) can, however, excite the mechanism of biosynthesis of vitamin C to some extent in rabbits.

Work has also been undertaken to study the influence of vitamin C in accelerating the process of ketolysis, as well as in checking the process of glycogenolysis by perfusion experiments with kidney and liver slice respectively in the Ringer's solution modified by Krebs[9]. 5 mgm. of vitamin C per c.c. of the reaction mixture is found to accelerate ketolysis by 70 per cent in thirty minutes in a solution containing 200 mgm. of sodium aceto-acetate per c.c.; and 2 and 5 mgm. of vitamin C have been found to inhibit the degree of glycogenolysis by 37 per cent and 60 per cent respectively in one hour.

Further work is in progress.

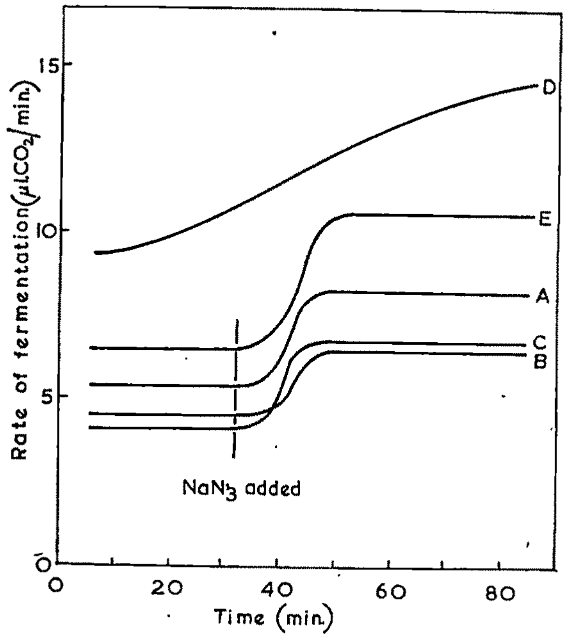
Use of Certain Growth-Inhibitors as Tools in Metabolic Investigations

CULTURES of *Saccharomyces carlsbergensis* grown in the presence of sub-optimal amounts of vitamin B6, biotin, or pantothenic acid, and containing in each case less than one tenth of the normal quantity per mgm. of the growth-factor, possessed reduced rates of fermentation, which could be increased within a few minutes at most by addition of the latter. A rapid and marked stimulation was produced also by the addition of sodium azide in suitable concentrations; typical results are shown in the accompanying figure.

Sodium azide did not increase the rate of fermentation of the normal yeast in the medium containing ammonium sulphate (*D*). Growth of each yeast, in contrast, was strongly inhibited by the same concentration of azide.



Influence of vitamin deficiencies and sodium azide upon rate of fermentation by *S. carlsbergensis*. *A*, B6-deficient; *B*, pantothenic acid-deficient; *C*, biotin-deficient; *D*, and *E*, grown in medium containing all essential growth-factors. The liquid in the manometers contained glucose (3 per cent), KH_2PO_4 (*M*/30), $(NH_4)_2SO_4$ (2·5 mgm./ml.), and usual amounts of other mineral salts; $(NH_4)_2SO_4$ was omitted in *E*. Sodium azide was added at the points indicated; effective concentrations were 5×10^{-5} *M* for *A* and *E*, and 10^{-5} *M* for *B* and *C*. All fermentations were run at 30° C. in an atmosphere of nitrogen. 1 mgm. (dry weight) of yeast was used in each experiment

Sodium azide, 2 : 4-dinitrophenol, and possibly certain other cell-poisons appear to release fermentation and respiration from the controlling influence of endergonic processes, exercised through the transphosphorylation mechanisms[1,2]. In view of this, the above results appear to indicate that vitamin B6, biotin, and pantothenic acid do not participate directly in the reactions involved in alcoholic fermentation; but influence the latter only indirectly by probable functions in the anabolic activities of the cell.

Retinene₁ and Indicator Yellow

Ball, Collins, Morton and Stubbs[1] have found that retinene$_1$ may combine with various proteins and amino-acids to give compounds with the properties of Lythgoe's indicator yellow. This is an interesting advance in the chemistry of vision; but, as stated by Dartnall[2], does not prove that indicator yellow is a "fortuitous artefact having no direct relevance to visual chemistry".

However, Lythgoe's statement[3] that he was unable to extract retinene from bleached visual purple solutions, using petroleum ether alone as a solvent, has recently been shown by me to be erroneous[4]. Lythgoe failed probably because he did not shake his extract with enough vigour to compensate for the slow diffusion of the liberated retinene through the aqueous phase to the petroleum ether. Furthermore, even in the presence of an 'active agent' such as alcohol, retinene is not released to petroleum ether during a period of 2–10 min. after the solution is bleached[4]. This supports Dartnall's view that retinene itself is not split off the visual purple molecule by light. The actual photo-product is probably Lythgoe's transient orange[5].

Dartnall states "that when one quantum of light is absorbed one chromophore is altered, but there is no evidence for the statement, often occurring in the literature, that the secondary process following activation of the chromophore is a loosening, that is, a dissociation of the chromophore-protein bond". A similar conclusion[6] was reached on the basis of a comparative study of the squid visual purple, cephalopsin[7]. This substance is a retinene$_1$ compound which is chemically almost identical with vertebrate visual purple, but is not normally dissociated by light, either in solution or in the most sensitive preparations of living retinas[8]. An increase in retinene release from illuminated squid retinas has been reported[9], but has been shown to be an artefact[8].

Ball, Collins and Morton[10], in their answer to Dartnall, state that there are three materials in bleached solutions of rhodopsin: retinene, and the acid and alkaline forms of indicator yellow. However, according to Lythgoe[3] there are two forms of acid indicator yellow: a stable form with adsorption maximum at 450 mμ below *p*H 4 and an unstable form with absorption maximum near 445 mμ between *p*H 4 and 6. The unstable form of acid indicator yellow readily releases retinene when its solutions are shaken with petroleum ether[4], and thus probably corresponds to the "loosely bound retinene" mentioned by Ball, Collins and Morton.

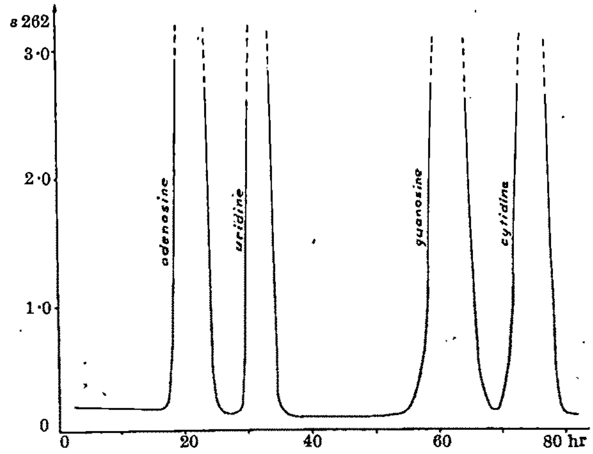
Partition Chromatography on Starch of Ribonucleosides

DURING work on ribonucleic acid turnover with nitrogen-15 in this Department, we found it necessary to isolate the different nitrogen-containing substances from small amounts of ribonucleic acid. It was thought that partition chromatography on starch as introduced by Elsden and Synge[1] might give a possible solution to our problem. Vischer and Chargaff[2] have applied partition chromatography on paper to the purine-bases; Edman, Hammarsten, Löw and Reichard[3] have worked out a method for separating guanine and adenine on a starch column. Tinker and Brown[4] have recently applied Craig's counter-current distribution technique to purines and pyrimidines and related compounds.

In regard to the pyrimidine bases, it seemed to be difficult to prepare them in a good yield from ribonucleic acid without destruction and conversion of cytosine to uracil during hydrolysis. The preparation of the ribonucleosides, however, was thought to be a simpler task, and a method for separating them from a mixture of the pure compounds on a starch column has been worked out.

The solvent chosen was butanol saturated with water. The starch was prepared by extracting ordinary commercial potato starch with methanol for 24 hours in a Soxhlet apparatus. The starch column was 200 mm. long and had an inner diameter of 23 mm. About 5 mgm. of each of the four pure ribonucleosides were dissolved in about 3 ml. of butanol–water and added to the top of the column. The butanol was run continuously for about three days; a sufficient head of liquid was kept in the column so that 5–7 ml. of fluid ran through the column per hour. The effluent was collected each hour by a simple apparatus constructed by Edman[5], and analysed in the Beckman spectrophotometer at 262 mμ. In this way the nucleosides may be easily localized (see graph). The different nucleosides have specific light absorption maxima around 262 mμ and may be characterized by comparing the light absorption at 262 mμ (maximum for uridine and adenosine), 248 mμ (guanosine) and 270 mμ (cytidine). Under these conditions, the values of *R*, according to Martin and Synge[6], for the different nucleosides were as follow: adenosine, 0·80; cytidine, 0·21; guanosine, 0·28; uridine, 0·52.



Separation of 4 mgm. of adenosine, uridine, guanosine and cytidine on a starch column 200 mm. long with butanol-water as the mobile phase

Samples containing the same nucleoside were combined, the solvent evaporated off and the residue dissolved in 0·1 *N* hydrochloric acid. The purity of the different compounds after chromatography was established by determining the ratio ε max./γ nitrogen per ml. These values obtained were: adenosine 0·196 (ε = 257 mμ); cytidine, 0·295 (ε = 280 mμ); guanosine, 0·164 (ε = 255 mμ); uridine, 0·332 (ε = 262 mμ).

The yield with about 5 mgm. of each nucleoside was 90–100 per cent. This method has been successfully applied in tracer experiments to hydrolysates of ribonucleic acid. The hydrolysis of ribonucleic acid to nucleosides was carried out with a pyridine–water mixture by a modification of Bredereck's method[7]. The results of these experiments will be published elsewhere.

EIGHTEENTH SESSION OF THE INTERNATIONAL GEOLOGICAL CONGRESS

An outline of plans for the eighteenth session of the International Geological Congress was given in *Nature*, August 7, p. 232. The proceedings lasted in all for a period of seven weeks during August and September. Much of the time was occupied by a series of thirty-seven long geological excursions, which visited important localities throughout Great Britain and eastern Ireland. Some 250 British geologists acted as organisers, directors and secretaries for these excursions and for an extensive series of additional short excursions centred on London. Despite indifferent weather, the excursion programme was extremely successful; it was clear that the excursion parties, which consisted predominantly of geologists from abroad, found interest and enjoyment in visiting the classic areas and type localities of the British Isles under the guidance of British specialists.

The formal and scientific meetings of the Congress, with an associated programme of receptions and entertainments, were held in South Kensington during August 25–September 1. The total membership of the session, including non-attending members, was more than 1,760; the total attendance of members and relatives was about sixteen hundred, including some nine hundred from overseas. Seventy-six different countries were represented; sixty-four Governments and 360 universities, societies and institutions sent official delegates.

This widely representative assembly provided the first full-scale opportunity for international geological discussion for eleven years—since the seventeenth session in Moscow; and throughout the Congress members made good use of the opportunity. The attendance at all the meetings and functions was very large. At times five sectional meetings, each with an attendance of some two hundred members, were simultaneously in progress. Audiences of nine hundred filled the lecture theatre of the Royal Geographical Society to hear special addresses by Prof. O. T. Jones and Sir Edward Bailey on "The Structural History of Britain". Colour films of the Mexican volcano Paricutin, presented by Dr. J. G. Reyna and Dr. F. H. Pough, and of the Virunga volcanoes of Africa, presented by Prof. T. W. Gevers, were shown twice because the same theatre could not hold at one time all who wished to see them. More than fourteen hundred members attended a reception by H.M. Government on the first day of the session, and a similar number were present at a reception by the Geological Society on August 31. Some six hundred official delegates and relatives were received by the Vice-Chancellor of the University of London on August 30, and many other receptions and entertainments were also successfully arranged. In addition to the formal items of the programme, members made full use for informal meeting and discussion of extensive lounge accommodation in the Geological Survey and Museum, which was the headquarters and registry of the Congress.

At the inaugural meeting in the Royal Albert Hall, Prof. H. H. Read, president of the Geological Society of London, was elected president of the Congress. Viscount Addison, Lord Privy Seal, welcomed the assembly on behalf of H.M. Government, and Sir John Anderson, honorary president of the General Organising Committee, explained how, under the ægis of the Geological Society and with active Government support through the Geological Survey and Museum, professional and amateur geologists throughout Britain had worked in face of considerable difficulties to make the Congress a success. From speeches by the heads of Government delegations at the final meeting of the general assembly on September 1, and from much informal comment, it can be judged that the delegates and members were, in fact, well pleased and satisfied with the arrangements which had been made.

During the session, the Council of the Congress arranged for the reconstitution of many of its international commissions, the work of which had been interrupted during the War. A full account of the proceedings of the Council, and of the sectional meetings, to which some 350 papers were offered, will be published in the report of the Session, but at least twelve months must necessarily elapse before this can be issued. Meanwhile, summaries of the more important decisions of the Council, and of the sectional proceedings, will appear in forthcoming numbers of the *Geological Magazine*. Further articles will also appear in *Nature*.

The Congress accepted with pleasure an invitation from the Government of France to hold the nineteenth session in Algiers in 1952. At the same time it expressed its gratitude for an invitation from the Government of India, and it is hoped that the invitation to meet in India may be renewed at the nineteenth session.

SCHOOL OF PHARMACY, UNIVERSITY OF LONDON

The Dean of the College of the Pharmaceutical Society announced at the 107th inaugural meeting on October 6 that the College is to be reconstituted on an independent basis and renamed the School of Pharmacy, University of London. It will be financed mainly from University funds.

This event marks the end of a phase of pharmaceutical education in Britain which was identified with the efforts of the members of the Pharmaceutical Society, who from their foundation in 1841 proceeded energetically to raise the status of their calling by promoting a modern system of professional education. Their aim was reaffirmed in the charter which the Society obtained in 1843, the objects of which included "the advancement of chemistry and pharmacy and the promotion of a uniform system of education". In pursuance of this policy the Society founded in 1842 what was at first known as the School of Pharmacy, the name being changed in 1926 to "The College of the Pharmaceutical Society".

The history of the School is a record of an attempt by a professional body to carry the burden of its own educational advancement, and all will join in paying tribute to the Society for success in that aim. The School from its inception has made outstanding contributions to our knowledge of pharmacy, chemistry, materia medica and medicine. The record of more than a century of endeavour is one which must redound to the credit of the Pharmaceutical Society. In 1842, with the prescience of enlightened educationists, the Society equipped and staffed a pioneer establishment on a scale which ultimately yielded rich dividends. A chemistry laboratory was established in that year which was one of the first of its type in Great Britain and which would at that time bear comparison with the best of its kind in Europe. It has housed a long list of distinguished professors, each of whom added an important quota to his science. Thus in chemistry we see the names Aufield, 1862; Tilden, 1865; Palmer Wynne, 1896; Collie, 1902; Crossley, 1904; and Dunstan, 1905; and in botany those of such figures as Robert Bentley, 1849, and Reynolds Green, 1887. In pharmacy and materia medica came Pereira, Redwood, Ince, Greenish and Wallis. The early days of the School saw the development of the use of the microscope by Greenish in the evaluation of powdered drugs. Its latter years saw the establishment, by Burn, of pharmacological laboratories for research work in methods of biological assays, and the years between had a record of steady achievement which was marked in 1926 by the recognition of the School by the University of London as a School of the University and by the establishment of a degree in pharmacy.

The reconstitution of the School brings to an end a fruitful regime of a hundred and six years, and inaugurates a new era which it is hoped to make even more productive of benefit to pharmacy than the old. Under its new title, the School will have an independent existence with a new governing body, a Council which will consist of the Dean (Prof. H. Berry), together with the following members: (*a*) nominated by the University of London: Dr. O. L. Brady, Sir Archibald Gray, Mr. John Hunter and Dr. G. B. Jeffery; (*b*) nominated by the Academic Board of the College: Prof. G. A. H. Buttle, Dr. Katharine Coward, Dr. J. W. Fairbairn and Prof. W. H. Linnell; (*c*) nominated by the Pharmaceutical Society: Mr. W. S. Howells, Mrs. J. C. Irvine, Mr. H. N. Linstead and Mr. C. W. Maplethorpe; together with three co-opted members: Sir Henry Dale, Mr. W. J. C. Quarrell and Sir Harry Jephcott, who becomes chairman of the new School Council. Mr. S. R. Curtis has been appointed secretary to the School.

BRITISH EMPIRE CANCER CAMPAIGN

THE twenty-fifth annual report of the British Empire Cancer Campaign covers the work done during the latter half of 1947. To those not acquainted with the ramifications of modern cancer research, much of the work in the report will occasion surprise, owing to its apparent lack of connexion with the subject. But the fact is that the problem of malignant growth is inextricably bound up with peculiarities of cellular respiration, nutritional requirements, hormone balance and interaction of enzyme systems; and its study demands contributions from almost every branch of science.

In the sphere of radiation physics, work has been mainly concerned with preparing the way for the future use of high-voltage radiation and of radioactive isotopes. To this end refinements of methods for accurate measurement of dosage, which becomes of increasing difficulty and importance under these conditions, have been developed. Measurements of extraneous radiations likely to harm personnel engaged in radiation therapy have also been carried out. During the year, further studies have been made on the biological effects of radiations. The extreme rapidity with which cellular changes occur is astonishing. Thus Prof. J. S. Mitchell has shown that within seven minutes of exposing cultures of chick embryo fibroblasts to X-irradiation, alterations occur in the amount of substances in the cells which cause absorption of ultra-violet light of wave-length 2537 A. Ribose nucleic acid is believed to be largely responsible for such absorption; but the possibility that other substances may be concerned is receiving attention. By standard histological methods pycnotic changes in the cell nuclei of the membrana granulosa of large ovarian follicles can be demonstrated within four hours of irradiating rats (L. Halberstaedter and M. Ickowicz). By the use of radioactive phosphorus (P^{32}) uptake as a measure of thymonucleic acid formation, Mrs. B. E. Holmes has adduced evidence that therapeutic doses of X-rays reduce the synthesis of this substance, and that this reduction may be an integral part of the damaging effects of radiations. On the clinical side, an important practical outcome of A. Glücksmann and L. G. Spear's histological method of assessing the progress of radiation therapy in cancer of the cervix uteri has been that, on the strength of it, several cases have been submitted to radical surgery, irradiation having been abandoned although in some cases the clinical response seemed favourable. In every case examination of the operation specimens showed the malignant process to be active.

Among the clinical reports is an analysis from Birmingham of survival-rates of 1,367 cases of cancer of the breast observed between 1936 and 1942. The accepted clinical opinion that the results of surgery combined with radiotherapy are superior to those of either form of treatment alone receives statistical confirmation. Owing to the small numbers, however, it is not possible to decide whether pre-operative or post-operative irradiation is the more effective method; though in the series quoted, post-operative treatment gave the better results. From St. Mark's Hospital come some important figures relating to cancer of the rectum. Of 716 cases treated between 1928 and 1941, just under half survived five years or more. But the five-year survival-rate of cases with disease confined to the rectum was more than 80 per cent, whereas those in which lymphatic metastases were present had a five-year survival-rate of just over 25 per cent. The correlation between the histological appearance of the growths and the extent of metastases was high in this series. Lymphatic spread was present in 80 per cent of cases in which 'high grade' malignancy was reported histologically; but in only 20 per cent of those reported as 'low grade'. In a very full report by the Clinical Cancer Research Committee on malignant disease of kidney, bladder and prostate, the figures concern cases treated before œstrogen therapy had been introduced for the last-named disease, and will therefore be useful for comparison with similar figures when the results of such treatment are available.

Sir Ernest Kennaway's study of the effect of circumcision on the subsequent development of cancer of the penis has already excited comment in the medical Press. He finds that the operation protects against cancer if performed at eight days but confers no protection when carried out after the fourteenth year. "The failure of the operation deferred until the 14th year to give the protection given by it when carried out on the 8th day suggests that the train of events leading to malignant growth is set going early in life, and that removal of the cause does not then avert the development of cancer at a much later age." In the experimental field the component processes which constitute "the train of events leading to malignant growth" have been characterized with greater clarity during the last fifteen years. Dr. I. Berenblum and Dr. P. Shubik have now placed such studies on a quantitative footing. Dr. Berenblum had earlier shown that croton oil, itself non-carcinogenic, would cause growths to appear when painted on the skin of mice previously treated with doses of known carcinogens insufficient to provoke neoplasia. The late Dr. J. C. Mottram showed that a single painting of carcinogen was effective when followed by croton oil applications. Using different carcinogens and varying the number and frequency of croton oil applications, Berenblum and Shubik have shown that two entirely distinct mechanisms enter into the carcinogenetic process in mouse skin. The initial painting with carcinogen produces some invisible, irreversible alteration in a few of the cells of the painted area—the 'initiating' process. The 'initiated' cells remain dormant until stimulated into activity by a 'promoting' agent—in these experiments croton oil. The recognition of these two stages explains certain discrepancies which have been encountered in assessing the carcinogenic potency of certain compounds. A compound may be a powerful initiator but a poor promoter. If its activity is measured in terms of minimal dose response it will be labelled a powerful carcinogen, since this measurement is essentially that of initiating action; whereas if average latent period for tumour production is the measurement chosen, its activity will be poor, average latent period indicating promoting action.

Of medical interest is the finding of workers in Oxford that liquor picis carb. B.P., a commonly used coal-tar preparation, sometimes prescribed for long periods, contains 0·02 per cent benzpyrene, and produced papillomas in ten weeks when painted twice weekly on mouse skin. After twenty-six weeks, 50 per cent of survivors had tumours, more than half of which became malignant.

Further work on recently discovered carcinogens has been done during the year. A curious property of 2-acetylaminofluorene, namely, the production of epitheliomas of the external auditory meatal wall, is shared by 4-dimethylaminostilbene. Taking advantage of the characteristic brilliant fluorescence of the latter compound in ultra-violet light, Glasgow workers have shown that it is excreted in the cerumen, which would account for the unusual site of tumour growth.

Work on growth inhibitors at the Royal Cancer Hospital has been considerably extended. 4-N : N-di-(2 chloroethyl)-aminostilbene, which possesses the chloroethyl groups characteristic of the nitrogen mustards, has a marked but short-lived inhibitory effect on the Walker rat carcinoma. The N : N-di-2-chloroethyl side-chain was introduced into many aromatic amines, and marked inhibitory activity has been demonstrated in the aniline, *o*-, *m*- and *p*-toluidines, *o*- and *p*-anisidine, β-naphthylamine, and *p*-aminobenzoic acid derivatives.

Much work is presented on tumour viruses. Prof. R. D. Passey and his colleagues at Leeds have examined extracts of tissues from breast tumours, and normal tissues from high- and low-cancer strain mice by means of electron microscopy. Extracts made from all tissues and from the milk of high-cancer strains consistently show numerous spherical particles of the order of 250 A. diameter. These particles are absent, or only present sporadically, in similar material from low-cancer strains. Ultra-centrifugation at 60,000–120,000 *g* removes the particles from the extracts. Even after the drastic process of extraction employed, the samples in which the particles are numerous incite mammary tumours when inoculated into susceptible mice. The particles are thus closely associated with milk-factor activity; but the authors stress the need for caution in interpreting the findings.

The *British Journal of Cancer*, which is sponsored by the Campaign, has now completed a year of publication, and gives an indication of the quality and breadth of cancer research in Britain. The present report includes work from new centres, such as the University of Bristol, the Hebrew University at Jerusalem and the University of Glasgow, which indicate how the activities of the Campaign are still growing twenty-five years after its foundation.

D. A. G. GALTON

AN ELECTRON MICROSCOPE STUDY OF CELLULOSE IN THE WALL OF *VALONIA VENTRICOSA*

By DR. R. D. PRESTON and DR. E. NICOLAI
Botany Department
AND
DR. R. REED and A. MILLARD
Department of Biomolecular Structure,
University of Leeds

DURING the past thirty years or so, intensive investigation of cellulose by various physical methods has directed attention repeatedly to the possible existence of supermolecular units of structure ranging from 'fibrils'[1] some 0·4 μ in diameter and of indefinite length to small spherical or ellipsoidal particles of diameter up to 1·5 μ [2].

While this has lent colour to speculations by earlier workers based largely on microscopical observations[3], it has never been clear that the newer physical methods yielded any more precise a picture of these units than did mere microscopical observation; nor, indeed, could it be claimed that proof had ever been given of the concrete existence of any such units in the intact, untreated walls of plant cells. With the advent of electron microscopy, however, and especially following the notable advance in manipulative technique using metal shadowing and surface replication, it became at last possible to make a direct attack on this particular aspect of cellulose structure.

Few of the many existing electron micrographs of cellulose have been very informative other than to show that, under suitable treatment, cellulose can be broken down into fibrous bodies. This has been due largely to the unfortunate choice for experimental material of either drastically treated celluloses such as filter paper or of mechanically disintegrated cellular tissues which are difficult to manipulate and the photographs of which are, by their very nature, almost uninterpretable[4].

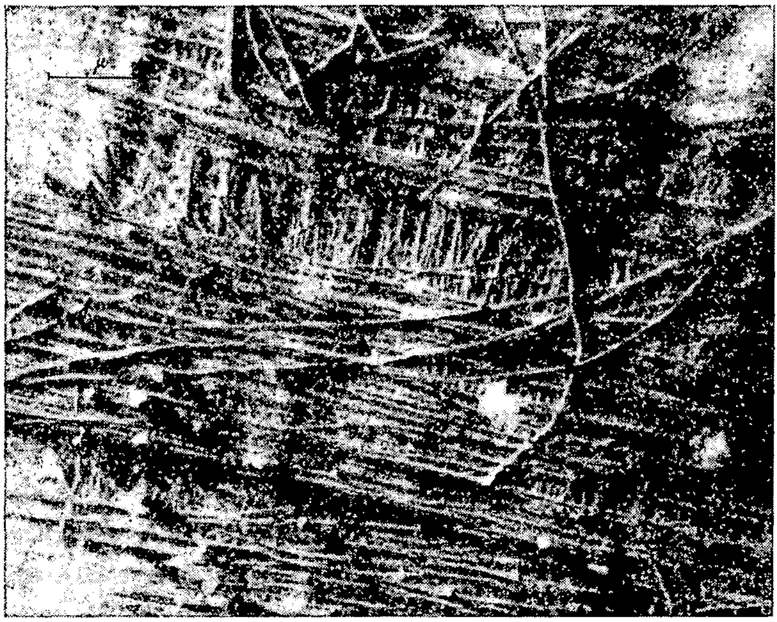

Fig. 1

The technique clearly demands a cell wall of large area, strong enough to be handled without material deformation, and the fine structure of which is already known in sufficient detail to make interpretation possible.

All these desiderata are fulfilled by the walls of the vesicles of *Valonia ventricosa*, and during the course of an intensive investigation of the cell walls of algæ initiated in the Botany Department at Leeds the organisation in this particular species, the fine structure of which is already well known[5,6], is being studied with the electron microscope. While the investigation is as yet only in the preliminary stages, the photographs obtained are already so striking that it has been thought desirable to direct attention to some of their more important features. It is not proposed to describe at this time the methods used in the preparation of the specimens examined in the microscope, except to say that all the photographs are of surface replicas, in 'Formvar' or collodion, of chromium-shadowed wall material cut from the vesicles without distortion.

Fig. 1 shows the appearance of the wall surface and Fig. 2 that of intermediate lamellæ in the wall laid bare by stripping and representing, if not the actual inner surface of the wall next to the cytoplasm, at least the condition very close to this surface.

Both photographs show a number of points of outstanding interest. First, and perhaps most unexpectedly, the wall appears to consist of fibres of indefinite length the diameters of which vary between surprisingly narrow limits around about 300 A. The uniformity alone of these fibres makes it rather certain that they are an intrinsic feature of the wall not artefacts due to intensive drying, etc., and can therefore be considered as fundamental building units of cellulose, at least as found in this particular alga. Certainly the particle hypothesis as proposed by Farr and Eckerson, upon which considerable doubt has already been cast[7], is once and for all shown invalid. The 'fibrils', on the other hand, already described for *Valonia*[8] are clearly aggregates of indefinite numbers of these fibres. At the same time, it is possibly significant to note that occasionally the clear impression is given of the presence in the wall of spherical particles, some 300 A. in diameter, linearly arranged and suggesting, therefore, a unit of smaller dimension.

Secondly, within any one lamella the fibres run closely parallel to one another, with the exception of occasional stray fibres which have probably been displaced during the preparation of the specimen. This is in harmony with the X-ray photographs[6].

Thirdly, in an adjacent lamella which can be observed through the interstices in the upper lamella, similar fibres are clearly visible which lie at an angle to the first set commonly rather less than a right angle (Fig. 1), but occasionally much less (Fig. 2), and sometimes a third orientation can be detected (Fig. 2). All this again is in harmony with the X-ray photographs, though at the moment it appears that

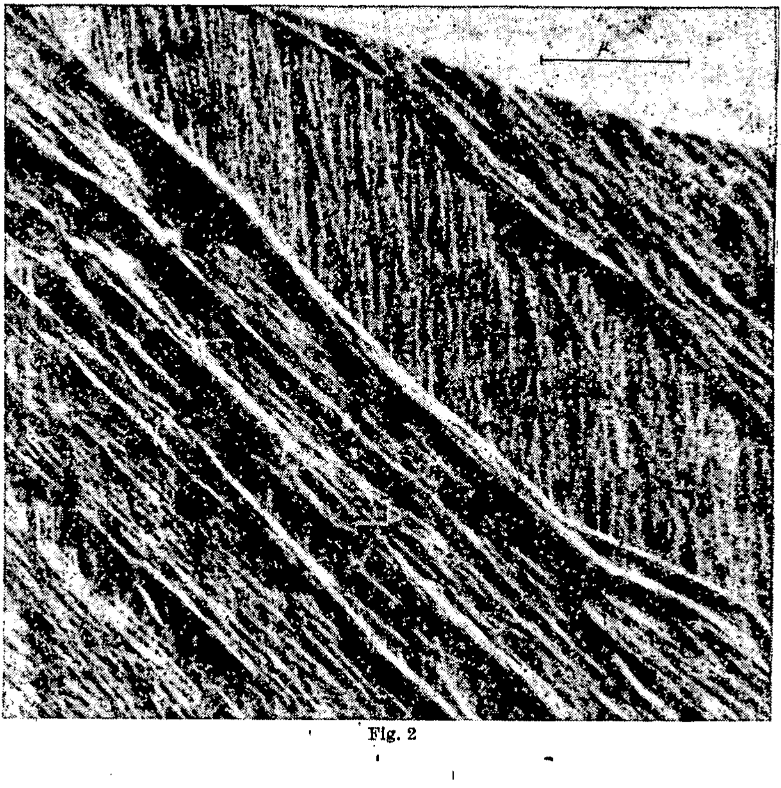

Fig. 2

the third orientation is more prevalent than these photographs gave reason to suspect.

It is clearly too early to speculate upon the precise nature of these fibres or to express any opinion as to the way in which they are produced by the plant. So far as the photographs go, however, they certainly give the impression that the fibres might be regarded as 'crystallites' of cellulose, and this would be in harmony with those properties of this particular wall which suggest a high degree of crystallinity. The density, for example, is the highest yet recorded[8] for cellulose (1·562) and suggests a crystalline/non-crystalline ratio of about 71 per cent. A determination of this ratio made for the senior author by P. H. Hermans of Utrecht (using his X-ray method), to whom our thanks are due, is on the other hand disappointingly low—lying between the values for native fibres and for wood pulp. This may, however, be due to impurities in the specimen sent to him. (A more recent determination on a purified sample is reported by Dr. Hermans to indicate a crystalline/non-crystalline ratio of 67–68 per cent.) The orientation of the fibres must be remarkably perfect, for it must be recalled that in this wall the molecular planes of 6·1 A. spacing tend to lie parallel to the wall surface. If the fibres are isodiametric in cross-section, such orientation could arise only through the prevalence of —OH groups in this plane, and would therefore presumably be initiated at the moment of deposition at the cytoplasm-wall interface, and not secondarily by changes within the mature wall. If, on the other hand, the fibres are flat ribbons (and the photographs as yet offer no evidence on this point), then the orientation could arise mechanically; though even then the orientation is not induced merely by drying, as it is in bacterial cellulose, for precisely the same condition has been demonstrated in undried algæ[9]. Finally, it should be noted that since the fibres run uninterruptedly with apparently smooth sides over distances much greater than 10 μ (width of the photographs taken), their appearance lends no support to the 'fringed micelle' hypothesis but tends rather to suggest the continuous, periodically distorted structure suggested by Meyer[10].

The senior author is indebted to Prof. W. T. Astbury, of the Department of Biomolecular Structure, for valued advice and for placing the facilities of the electron microscope at his disposal, and to the Department of Scientific and Industrial Research for a grant defraying in part the expenses of the algal research.

THE YOUNG WORKER IN INDUSTRY

AT the discussion on "The Young Worker in Industry" arranged by Section L (Education) of the British Association on September 13, the two main contributions were from representatives of industry and of the Ministry of Education. In the first paper, which dealt with recent progress in industrial education and training, the authors pointed out that the increasing scale and complexity of British industry since the industrial revolution has been paralleled by a widening appreciation of the need for industrial workers to know something of the principles underlying the industrial arts. The establishment of the mechanics institutes and, later, technical colleges, works' schools and junior technical schools was part of the practical response to this need, as was, more recently, the setting up of the system of national certificates and the part-time day release by industry of young personnel for technical study.

War-time demands for skilled personnel stimulated realistic thinking and practical developments in the fields of selection and training. War and the post-war economic difficulties have also thrown into relief the social need for maximum economy in the use of man-power. To secure this, it is essential that all young people receive the type of education and training best suited to their interests and natural aptitudes. In this, industry has an important part to play, not only in providing information regarding the types of careers available, but also in establishing training schemes, a function of which should be the assessment under practical conditions of the trainees' suitability, not with the view of 'weeding out' failures so much as of providing training for a suitable alternative occupation where one course of training proves inappropriate.

The story of national education in Britain between the two World Wars is one of the failure in the practical application of the ideals of the Fisher Act, followed by renewed planning represented by the reports of the Consultative Committee between 1925 and 1938. The trade recessions of this period also checked progress in industrial and commercial training, which was largely in the hands of private enterprise. Some enlightened firms, however, endeavoured to repair the gaps with their works' schools, some of which have a long history. The experience gained in these schools should be of value in connexion with the proposed county colleges. The interest which young workers have in further education is, in most cases, best stimulated by basing it on their work and environment. It is suggested that the initiation courses run by many firms to help young people to bridge the gap between full-time schooling and wage earning could be paralleled by wider courses, designed with the same intent, in the county colleges to be established.

Apprenticeship is an aspect of training in which appreciable progress has been made in industry since the end of the First World War, particularly in the more technical industries such as engineering. Some of the largest concerns have comprehensive apprenticeship schemes with grades according to the educational levels of entrants—craft apprenticeship for boys from secondary modern and secondary technical schools, student apprenticeship for boys from secondary grammar and from public schools, and graduate apprenticeship for young men and women graduates. The difficulty of smaller firms in supporting schemes on such an ambitious scale is one reason for the modern tendency to discuss and plan apprenticeship schemes at a regional and national level.

Attention has also been given to practical training at the professional level, particularly in the engineering industry. For example, the Institution of Electrical Engineers has published no less than three booklets on training for the electrical industry between 1942 and 1947. The report published in 1947 makes recommendations based on the best in modern training practice in this field, and lays down practical training standards designed to secure for the young professional engineer the width of experience and consequent flexibility necessary for the continued progress of the industry. One specific recommendation is that graduate apprentices should be given leave of absence by their firms to widen their experience not only in Great Britain but also overseas. This recommendation is already being carried out by some firms, and an increasing number of overseas contacts is being made. Many foreign students are coming to Great Britain for engineering training both theoretical and practical. There is no reason why an interchange of craftsmen and technicians, as well as young professional engineers, could not be arranged to give human reality to political and economic union between countries. Already the merits of British methods of training professional engineers are widely recognized. If this reputation can be extended to other industries and vocations, Britain will have made a contribution to world prosperity equal to that made by its scientific men in the field of knowledge.

The second paper, by a representative of the Ministry of Education, indicated that it has always been traditional in Great Britain for our educational institutions to provide for the educational needs and interests of the young worker rather than for the needs of industry as such, and that likewise it is traditional for industry to take responsibility for the practical training of its young workers and to look to our educational institutions for the provision of technology and general education. The needs of industry and the interests of young people are not always identical, and it was to avoid indiscriminate recruitment regardless of aptitudes that the Juvenile Employment Service—now called the Youth Employment Service—was set up. To be fully effective, this Service must have the support of parents, teachers and employers, and be staffed with officers expertly trained in vocational guidance and having a wide knowledge of industrial conditions, so as to effect good 'placing' and to 'follow up' such placing. Much research is called for in this field.

The educational needs of young workers once they are in industry are very varied, depending on their educational level at entry and on their aspirations; but that further education must be available is now an accepted need for all. Only 30–40 per cent of 'school-leavers' at present receive any further formal education.

Of these, too high a proportion can only acquire their technology at night at the expense of their leisure, and a 40-hour week for the adult should not make us indifferent to the 60-hour week of many apprentices. The larger firms which provide systematic industrial training in works' schools usually have a close link with the technical colleges and appreciate the need for day-time release—200,000 young workers are now released for such training as compared with 40,000 in 1938. In the smaller works, many are too small to provide even good practical training facilities.

The provision of the 1944 Education Act for compulsory day-time release for young people up to the age of eighteen years tries to provide a partial answer to the problem of the youth who ends his formal education at the school-leaving age of fifteen—'partial' because industry must attempt to do its share and the work in the county colleges to be set up under the Act should be complementary to industrial training. Within the past few years, some hundreds of education officers and personnel managers have been appointed by industrial employers for the specific purpose of furthering educational activities, and their influence is already having a marked effect. But such developments are limited in general to the larger industrial firms, and the problem of the smaller firms still remains. There are a number of ways in which the educational system can help to make up for the deficiencies of education and training within industry. One is to send young apprentices to the local technical college for full-time training for one or more years, and another is to release apprentices for 'sandwich' courses in colleges for full-time periods of varying length followed by part-time day release.

Pressure from industry to augment facilities for further education of the young worker is causing the Ministry of Education some embarrassment. The county colleges cannot at present be introduced. The difficulties of interesting the bulk of adolescents, who by the very nature of the industrial structure of Britain must become unskilled workers, in further education are well recognized; but if successful, the education provided by the county college will solve many problems. It will lay a foundation for adult life; develop regular habits of study and work; a pride in a job well done; a healthy interest in recreational pursuits, and fit the young people to play their part in the struggle for industrial survival.

Although not yet ready to introduce the county colleges, the local education authorities in Britain have been asked to plan their provision as an integral part of the whole field of further education. In the large cities there will be one or more central colleges for advanced studies for those over eighteen, and satellite branch colleges to meet the varied needs of those under eighteen. Vocational training and general education will not be separated. In smaller cities and towns there will be small colleges to meet the needs of day and evening courses for youths and adults.

A vital problem in educating youth in industry is to secure permanent liaison between the colleges and industry, and it is hoped that this has been effected by the nation-wide system of Regional Advisory Councils, consisting of representatives of industry and the colleges, the local education authorities and the universities.

The system of further education and training in Britain is complex and untidy; but it has achieved success largely by its voluntary nature, for it is democratic and flexible and comparatively easy to develop in the ways best suited to our people. The technical colleges employ large numbers of expert technologists from industry as teachers, and it is hoped this will continue when the training is carried on in the day-time. The Ministry has been encouraging developments by setting up three training colleges for the training of technical teachers, by facilitating the release of teachers to industry and by encouraging research.

In the discussion which followed the main papers, reference was made to the valuable assistance being given by some industrial concerns to technical education by providing materials and teaching staff. One speaker stressed the need that the selection of vocations should not be made too early; another that small firms had the one great advantage of being able to keep in closer touch with their young workers than can the larger concerns. Listening to all the contributions to the session, one was particularly struck with the obviously growing interest of industry in the education and training of the young worker, and the growing co-operation between employers, organised labour, and the education authorities.

A. P. M. FLEMING

SOCIETY FOR APPLIED BACTERIOLOGY

THE annual general meeting and conference of the Society was held during July 27–30 in the Department of Agriculture, Queen's University, Belfast. Approximately a hundred members and visitors attended the conference.

Agriculture, and particularly dairying, being the principal industry of Ulster, papers on dairy bacteriology predominated among the seventeen contributions submitted to the conference. The first session, on July 27, was devoted to four papers from Northern Ireland workers.

Mr. P. L. Clerkin, of the Bacteriology Division, described the development of the dairy industry in Northern Ireland during the past two decades with particular reference to the methods of bacteriological control. A feature of the Northern Ireland procedure for raw milk is the classification of liquid supplies into three grades designated simply *A*, *B* and *C*. Grade *A* is the produce of tuberculin-tested herds, bottled on the farm and sold raw. It must conform to fairly high bacteriological standards. Grades *B* and *C* have lower bacteriological standards and the bulk of such supplies is pasteurized. To assist the ready identification of the milk by the consumer, coloured labels, bottle-caps, etc., were assigned for each grade. This procedure was of interest since the authorities in Great Britain have consistently masked the identity of graded milk supplies under names which convey little or no information to the consumer. Legislation controlling ice-cream quality was introduced in Northern Ireland in 1938 and the Bacteriology Division advised on suitable hygienic standards. In this field, the Ulster authorities have been in advance of England and Wales.

Drs. Lamont and Kerr and Mr. McGirr, of the Northern Ireland Veterinary Division, submitted a paper on the Stormont technique of tuberculin testing. This technique was based on observations indicating that, in the tuberculous bovine, intradermal tuberculin injections exhibited increased sensitivity to a second tuberculin injection given seven days after the primary inoculation. The diagnostic feature is the increase in skin thickness and *not* the nature of the reaction. Results are now available for 590 animals subjected to the new procedure and afterwards slaughtered for post-mortem examination. The results showed that the Stormont test had a total error of 3·4 per cent, of which 2 per cent were undetected infected animals.

Lamont and his co-workers have also studied the white blood cell changes in relation to tuberculin testing with particular reference to the new technique. The most striking finding is that the blood reaction with the Stormont technique is very marked, there being a pronounced rise in the polymorph-lymphocyte ratio. The maximum alteration in the ratio appears at varying periods, hence for diagnostic purposes multiple bleeding would be necessary. Using white blood cells, Lamont and his colleagues have succeeded in passively transferring tuberculin sensitivity from the bovine to guinea pigs. These findings offer fairly concrete proof of the presence of the antibody responsible for tuberculin sensitivity. In general, this work supports the thesis recently propounded in a number of American publications that white blood cells and particularly lymphocytes play a very important part in the genesis and manifestations of many immune phenomena.

Dr. Pearson, also of the Veterinary Division of the Ministry, presented a paper on the limitations of penicillin in the treatment and control of bovine mastitis. The North of Ireland experience indicates that clinical mastitis, as encountered by the veterinary surgeon, requires much more individual consideration than is usually given, before penicillin is prescribed. The symptoms of streptococcal and staphylococcal infections are becoming more and more difficult to differentiate, and in Ulster in recent years there has been a definite increase in staphylococcal infections of the udder. In many of these cases little or no response has been shown to penicillin therapy, the organisms being invariably penicillin-resistant. This resistance may possibly have developed during previous penicillin treatment of sporadic mastitis. Strains of resistant streptococci have not become such a problem although such strains undoubtedly exist. Treatment of *Corynebacterium pyogenes* mastitis with penicillin has been found to be a waste of time and money. During recent years there has been a marked increase in the number of samples from clinically positive cases of mastitis, where it has been impossible to detect any causal organisms either culturally or microscopically.

Mr. J. G. Murray, of the Bacteriology Division, contributed a paper on ropy contamination of pasteurized milk. In a recent outbreak the principal source of such organisms was found to be contaminated milk bottles, *Bacterium aerogenes* being the principal contaminant. These organisms were frequently missed when incubated in bile salt broth at 37° C.; but at 22° and 30° C. they were readily detectable. Mixed cultures of slime-producing organisms were also occasionally present.

The second paper-reading session, on July 28, opened with a paper on factors affecting the bacterial population of lake waters by Dr. C. B. Taylor, of the Freshwater Biological Association, Wray Castle, Ambleside. The bacteria present in lake water may be considered in three categories: (*a*) those washed in from outside sources, of which a large population will ultimately perish although others may find conditions suitable for growth; (*b*) indigenous bacteria capable of existence in a dilute nutrient solution, as represented by lake water, and able to use for growth low concentrations of available organic matter, such types being probably ubiquitous; (*c*) bacteria dependent on a solid surface for their proliferation and found in connexion with plankton cells. Group (*a*) reflect the amount of pollution in the watershed, and their numbers in the inflowing water are at the maximum for a few hours after heavy rain. Normally they only mix with the lake water to an appreciable extent in winter. Group (*b*) are types with very weak physiological activity and very low powers of resistance to unfavourable circumstances. An appreciable number are pigmented, yellow being the most common colour. This group is at its most numerous during the winter months. Group (*c*) are most common during periods when algal cells are present to afford sites for attachment.

Dr. Taylor, along with his colleague, Mr. C. H. Foot, also presented a paper on the most suitable medium for growth of bacteria from water. An interesting point in their findings was the fact that sufficient available nitrogenous organic matter is present in ordinary agar to satisfy the requirements of most water bacteria. Plain agar with the addition of salts, incubated at 20° C. for ten days, reproduced 80 per cent of the colonies found on a standard medium. Beef extract, a concentration of 0·5 per cent peptone and nitrate ($NaNO_3$) were found to be restrictive to bacterial growth.

Dr. Cunningham and Mr. McLeod, of the East of Scotland College of Agriculture, presented a short paper on the occurrence of *Bact. coli* Type I coliform organisms in the bovine udder. The evidence of the occurrence of persistent coliform infection of the udder in the absence of macroscopic symptoms is weak. In the case quoted by Cunningham and McLeod the numbers of organisms varied between 25 and more than 1,000 per ml. but usually were of the order of a few hundred. The numbers varied only slightly from day to day and also in the foremilk, mid-milk and strippings. During the course of the investigation the cow went dry, and after calving the same quarter was again found to be infected. The practical importance of the finding is the fact that the coliform test is still applicable in Scotland for designated milk and, in the case in question, the milk supply failed to satisfy the required standards when the milk from the infected animal was included in the bulk milk of the herd.

Mr. A. Rowlands and Mr. W. A. Hoy, of the National Institute for Research in Dairying, Reading, presented the results of experiments with the lye (or caustic soda) method of treating milking machine teat cup clusters and milk tubes. This method is almost universal in the United States; but so far has not been given official backing in Great Britain. The Reading results were entirely satisfactory even under known unsatisfactory conditions. Chlorination of the lye solution was found to be a useful additional safeguard.

In the final paper-reading session, on July 30, Miss M. E. Sharpe, of the National Institute for Research in Dairying, discussed some of the biochemical characteristics of Group *D* streptococci isolated from infants' fæces with special reference to their tyrosine decarboxylase activity. A definite association was found between tyrosine decarboxylase activity and the biochemical characteristics on which the subdivision into species has been made. *Str. fæcalis* and its varieties *zymogenes* and *liquefaciens* show a high tyrosine decarboxylase activity. *Str. durans* has an intermediate activity and *Str. bovis* and the unclassified strains have little or no activity. No strains of Group *D* streptococci which ferment raffinose produced tyrosine decarboxylase.

Miss E. R. Hiscox, of the National Institute for Research in Dairying, Reading, dealt with some of the factors affecting the ripening of pasteurized milk cheese. Since cheese-making is now largely a factory process, pasteurization of the milk prior to manufacture affords the advantages of standardization, uniformity and elimination of many faults. The cheese, however, as a rule is slower in ripening and lacks the typical flavour of the variety concerned. In Miss Hiscox's investigations raw milk cheese had twice the volatile acidity of the pasteurized milk cheese and few lipolytic organisms were found in the pasteurized milk cheese. Since flavour is probably the combined effect of fat lipolysis and volatile acids, the reason for poor flavour development in pasteurized milk cheese is apparent. The question has now arisen whether flavour can be restored by the use of suitable inoculants, and recent American work has been directed to this end.

Mr. J. Wolf, of the University of Leeds, submitted a short paper on the germicidal properties of tar acids present in producer gas tars. The germicidal properties of these tar acids are rather low as determined by the Rideal-Walker coefficient. A marked increase in the Rideal-Walker coefficient was attained when the tar acid emulsion was chlorinated by various methods. This work suggests that tar acids from producer gas tars might provide a useful source of germicides.

The subjects covered by other papers included a review of the microbiology of composting; the survival of the microflora of milk powders at different relative humidities; a modified acidity test for use on the milk reception platform of dairies, and studies of the thermoduric bacterial flora of raw milk.

Details of the papers will be published in due course in the *Proceedings of the Society for Applied Bacteriology*, the editor of which is Dr. T. Richards, Department of Agricultural Bacteriology, University of Reading.

FREE ENERGY OF PROTEIN SOLUTIONS

THE annual general meeting and conference of the Society of Leather Trades' Chemists was held on September 17 and 18 at the University of Leeds, Mr. G. Jessup Cutbush, vice-president of the Society, presiding. Included in the proceedings was the delivery of the third Procter Memorial Lecture, by Mr. G. S. Adair, reader in biophysics, University of Cambridge, who spoke on "Recent Work on Osmotic Pressures, Membrane Equilibrium and the Generalized Free Energy of Protein Solutions in the Light of the Work of Procter". Mr. Adair remarked that this year is the centenary of the birth of Henry Richardson Procter, and the occasion was also noteworthy since the commemoration lecture was being delivered in Leeds, where his work was carried out.

Procter's theory of the swelling of gelatin in hydrochloric acid was described by Loeb as one of the most original and ingenious contributions to modern science. The theory gives a remarkably clear and simple account of the large changes in the osmotic pressures of proteins caused by acids and alkalis. Much work remains to be done to elucidate the smaller effects caused by different salts. Recent experimental observations on hæmoglobin in phosphate buffers show an increase in osmotic pressure in-the more acid and the more alkaline solutions, in general agreement with the theory; but the point for minimum osmotic pressure is on the acid side of the pH for minimum combination with acid or base. The difference may be as much as 0·2 pH units for 0·01 molar phosphates and 0·7 units for 0·05 molar phosphates.

Measurements of the membrane equilibrium of ions, if allowance is made for hydration of the protein, indicate that hæmoglobin causes relatively small changes in the activities of cations like sodium, potassium or ammonium, and relatively large diminutions in the activity coefficients of phosphate and chloride ions[1].

A reaction of the following type might cause similar changes in ion distribution and osmotic pressure:

$$-\mathrm{Pr}^{+} + \mathrm{Na}^{+} + \mathrm{Cl}^{-} = [\mathrm{PrCl}]^{-} + \mathrm{Na}^{+},$$

where $-\mathrm{Pr}^{+}$ denotes a protein double ion, $[\mathrm{PrCl}]^{-}$ a protein ion with a combined or associated chloride ion neutralizing one positive charge. Although salts tend to diminish the osmotic pressure in the range of concentrations studied by Procter and Wilson, they usually increase the pressure in the range where most of the observed pressure is due to the protein itself.

This observation might be explained if groups on the surface of the protein molecule can attract either an inorganic ion or a second protein molecule. If many inorganic ions are present, the chance of attracting a second protein molecule is diminished, and the osmotic pressure should be increased. The effect may be compared with a diminution in the term a in van der Waals' equation for gas pressure. The net excess of salt associated with a protein can be correlated with its solubility and activity.

In studies of the effects of electrolytes on swelling and osmotic pressure of proteins, reproducible results are most readily obtained by the use of relatively large volumes and several changes of the external liquid or dialysate, preferably a buffer mixture with a well-defined pH value.

The chemical potentials of salts, acids and water must be the same on both sides of the membrane in a state of equilibrium[2]. Buffer mixtures can be used to control the potentials in a series of protein solutions in a manner comparable with the control of temperature by a thermostat. Thermodynamical formulæ applicable to dialysed protein solutions may be derived from a function A_G, a revised form of the first definition[3] of which is stated as follows: the function A_G, termed the generalized free energy, of any system is equal to the total energy of the system, minus the sum of all individual forms of energy that include an intensive factor controlled by an external system.

The factors here termed intensive are the temperature, T, the pressure with a negative sign, $-P$, $(-P = \delta U/\delta V)$, and the chemical potentials. The total energy of a fluid, U, is regarded as the sum of at least three individual forms of energy, the thermal energy TS, the mechanical energy $-PV$ and the chemical energy $\mu_i n_i$ for substance i; S is entropy of the fluid; V is volume; n_i is number of molecules of i; μ_i is chemical potential of i.

In fluids with a constant mass of each substance, there are two intensive factors to consider, T and $-P$, four combinations of intensive factors, and four possible values for A_G, equivalent to the well-known functions termed energy, heat content, free energy of Helmholtz and free energy of Gibbs. If any of the potentials be controlled, an unlimited number of functions of the same type can be obtained by deducting products like $\mu_i n_i$ from the energy. All the functions are special cases of one function A_G, so that methods used in deriving thermodynamical relationships from the well-known functions[4] may be applied to more complex systems, such as dialysed protein solutions, where potentials are controlled. The formula $\mu_p = \delta A_G/\delta n_p$, for example, is valid for all systems if μ_p represents the potential of a non-diffusible substance, for example, protein. It will be remembered that Henry Procter himself was not entirely satisfied with standard forms of the second law of thermodynamics expressed in terms of entropy. A revised form of the law may be suggested as follows: the generalized free energy of any system tends to reach a minimum.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, October 25

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 5 p.m.—Prof. Frank Debenham: "The Great Ross Barrier of the Antarctic".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Hill, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "A Western European Power Network?" (to be opened by Mr. T. Graeme N. Haldane).

KING'S COLLEGE (in the Department of Electrical Engineering, Strand, London, W.C.2), at 5.30 p.m.—Mr. W. J. Gibbs: "Tensor Analysis Applied to Electrical Machines".* (Further Lectures on November 1, 8, 15, 22 and 29.)

PHYSICAL SOCIETY, LOW-TEMPERATURE GROUP (in the Lecture Theatre of the Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Prof. F. E. Simon, F.R.S.: "The Unattainability of Absolute Zero".

INSTITUTION OF THE RUBBER INDUSTRY, MANCHESTER AND DISTRICT SECTION (at the Engineers' Club, Albert Square, Manchester), at 6.15 p.m.—Mr. E. R. Thornley and Mr. G. A. Pittman: "A Dynamic Compression Test for Rubber/Cord Fabric Adhesion".

Tuesday, October 26

UNIVERSITY COLLEGE, LONDON (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. D. B. Fry: "Visible Speech".*

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Miss P. M. Kaberry: "The Position of Women in a Bamenda Tribe, British Cameroons".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Mr. F. Hoyle: "Stellar Evolution and the Expanding Universe". (Further Lectures on Tuesdays, November 2 and November 9.)

EUGENICS SOCIETY (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. Cecil Binney: "Legal and Social Implications of Artificial Insemination".*

INSTITUTION OF CHEMICAL ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. M. W. Thring: "The Construction of Models in which more than One Process is Similar to the Original".

INSTITUTION OF ELECTRICAL ENGINEERS, MEASUREMENTS SECTION (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Measurement of Phase Angle of Electric Circuits" (to be opened by Mr. Arvon Glynne).

SIR HALLEY STEWART TRUST LECTURE (at the Memorial Hall, Farringdon Street, London, E.C.4), at 6 p.m.—Prof. M. L. Oliphant, F.R.S.: "The Atomic Age—the Scientific Achievement".*

TEXTILE INSTITUTE, YORKSHIRE SECTION (at the Midland Hotel, Bradford), at 7 p.m.—Dr. H. J. Woods: "The Structure of Fibres".

ROYAL INSTITUTE OF CHEMISTRY (joint meeting with the WELWYN GARDEN CITY SCIENTISTS' CLUB, at The Cherry Tree, Welwyn Garden City), at 8 p.m.—Dr. T. S. Jones: "Polypeptide Antibiotics—Biological Polymers".

Wednesday, October 27

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY, CHEMICAL SECTION (at the Portico Library, 57 Mosley Street, Manchester), at 5.30 p.m.—Dr. E. J. F. James: "Chemistry and Education".*

INSTITUTE OF WELDING (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Dr. J. H. Paterson: Presidential Address.

Thursday, October 28

Chadwick Public Lecture (at University College, University Park, Nottingham), at 4 p.m.—Sir Arthur MacNalty, K.C.B.: "Advances in Preventive Medicine during the War of 1939–1945".*

Linnean Society (at Burlington House, Piccadilly, London, W.1), at 5.10 p.m.—Dr. Helga S. Hacker and Dr. P. H. Hacker: "Local Variations and Chances of Interbreeding in *Apodemus sylvaticus*, the Long-tailed Wood-Mouse".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Kenneth Clark: "Three 'Scientific' Painters", 1, Uccello. (Further Lectures on Thursdays, November 4 (Piero della Francesca), and 11 (Seurat).)

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Prof. K. Linderstrøm-Lang: "Micromethods in Biology".*

University of London (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 5.30 p.m.—Prof. K. de B. Codrington: "The Place of Archæology in Indian Studies".*

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—A member of the staff of Handley Page, Ltd.: "Aircraft Engineering and Production".

Royal Statistical Society, Sheffield Group of the Industrial Applications Section (in Room B1, The University, St. George's Square, Sheffield), at 6.30 p.m.—Mr. E. C. Fieller: "The Activities of the Mathematics Division of the National Physical Laboratory".

Manchester Statistical Society, Industrial Group (at the Society of Architects, 16 St. Mary's Parsonage, Manchester), at 6.45 p.m.—Mr. P. Armitage: "Sequential Methods of Sampling Inspection".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7 p.m.—Sir Robert Robinson, F.R.S.: "Strychnine, Brucine and Vomicine".

Pharmaceutical Society (at 17, Bloomsbury Square, London, W.C.1), at 7.30 p.m.—Mr. C. H. Hampshire: "The British Pharmacopœia, 1948".

Friday, October 29

Society of Public Analysts and other Analytical Chemists, Polarographic Discussion Panel of the Physical Methods Group (in the Main Chemistry Lecture Theatre, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 3 p.m.—Annual General Meeting; Discussion on "Polarography in Biochemistry".

Chemical Society, Glasgow Branch (joint meeting with the Andersonian Chemical Society and Glasgow University Alchemists' Club, at the Royal Technical College, Glasgow), at 3.45 p.m.—Prof. John Read, F.R.S.: "Chemical Personalities of a Century Ago".

Royal Astronomical Society (joint meeting with the Astronomical Society of Edinburgh, at the Royal Society of Edinburgh, 22–24 George Street, Edinburgh), at 4.45 p.m.—Scientific Papers.

Chemical Society, Newcastle and Durham Branch (in the Chemistry Department, King's College, Newcastle-upon-Tyne), at 5 p.m.—Prof. W. Baker, F.R.S.: "Recent Work on Systems of Aromatic Type" (Bedson Club Lecture).

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Prof. K. Linderstrøm-Lang: "Enzymatic Breakdown of Proteins, I".*

North-East Coast Institution of Engineers and Shipbuilders (in the Literary and Philosophical Society's Lecture Theatre, Newcastle-upon-Tyne), at 6.15 p.m.—Mr. S. S. Cook, F.R.S.: "Thermodynamics in the Making" (Andrew Laing Lecture).

Royal Statistical Society, Birmingham Group of the Industrial Applications Section (in the Chamber of Commerce, 95 New Street, Birmingham), at 6.30 p.m.—Mr. C. Wainwright: "Statistical Principles in Quality Specifications for Plastics".

Manchester Statistical Society, Industrial Group (in the Lecture Room of the Society of Architects, 16 St. Mary's Parsonage, Deansgate, Manchester), at 6.45 p.m.—Mr. P. Armitage: "Sequential Methods of Sampling Inspection".

Royal Institute of Chemistry (joint meeting with the Cambridge University Chemical and Metallurgical Societies, at the University Chemical Laboratory, Pembroke Street, Cambridge), at 8.30 p.m.—Sir Charles Goodeve, F.R.S.: "The Physical Chemistry in Iron and Steel Processes".

Saturday, October 30

Biochemical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 11 a.m.—Symposium on "Partition Chromatography and its Application to Biochemical Problems".

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 2.30 p.m.—Mr. R. D. Barnett: "Digging up Past Civilisations".*

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Deputy Director—The Director, Museum and Art Gallery, Newport, Mon. (October 30).

Principal and a Head of the Agricultural Department at Essex Institute of Agriculture, Writtle, Chelmsford—The Chief Education Officer, County Offices, Chelmsford (October 31).

Lecturers (2) in Horticultural Science—The Principal, Kent Horticultural Institute, Swanley (November 6).

Research Lecturer in the Department of Colour Chemistry and Dyeing—The Registrar, The University, Leeds 2 (November 8).

Principal Scientific Officer to control research and development of radio and radar navigation devices and aircraft approach and landing aids, a Principal Scientific Officer to control research and development of radio communication systems, airborne and ground; electro-acoustic and sound recording equipment; special test equipment for such devices, a Principal Scientific Officer to control development of general radio test equipment for Service use and special radio and electronic test equipment for test purposes, and a Senior Scientific Officer for the development of components for new radio equipment—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2300 (November 11).

Lecturer in Applied Mathematics—The Registrar, University College, Southampton (November 13).

Farm Manager at the Council's Institute of Animal Physiology, near Cambridge—The Secretary, Agricultural Research Council, 6a Dean's Yard, London, S.W.1 (November 15).

Lecturer in Pharmacology in the Department of Materia Medica, Medical School, Dundee—The Secretary, University of St. Andrews (November 30).

Professor of Veterinary Science at Makerere College, Kampala, Uganda—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (November 30).

Lecturer in the Department of Physics at Pietermaritzburg, and a Lecturer in the Department of Experimental Physics, at Durban—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (December 1).

Chair of Geology—The Registrar, The University, Nottingham (December 31).

Assistant Lecturer and Demonstrator in the Physiology Department—The Secretary, King's College of Household and Social Science, Campden Hill Road, London, W.8.

Director of the Jeremiah Horrocks Observatory—The Chief Education Officer, Municipal Building, Preston.

Entomologist to the States of Jersey—Dr. T. Small, 14 Esplanade, St. Helier, Jersey, Channel Islands.

Laboratory Technician—The Secretary, University College Hospital, Gower Street, London, W.C.1.

Lecturer in Chemistry—The Principal, Derby Technical College, Normanton Road, Derby.

Lecturer in Chemistry and a Lecturer in Physics—The Principal, Acton Technical College, High Street, London, W.3.

Mathematician to assist in theoretical research on the deformation of metals—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

Physical Chemist having some research experience in surface chemistry or in methods of examination of fine powders, and a Chemist with experience of inorganic analysis—Director of Research, British Whiting Federation, 26 Claremont Road, Surbiton, Surrey.

Research Biochemist in the Special Unit for the Study and Treatment of Juvenile Rheumatism—The Administrative Officer, Canadian Red Cross Memorial Hospital, Taplow, Maidenhead, Berks.

Research Engineer, Physicist or Metallurgist to take charge of a Rolling Mill Research Team, and a Research Engineer, Physicist or Metallurgist to initiate work on Forging, at Sheffield—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1.

Senior Geologist for Mines Department, Adelaide, to undertake and supervise geological investigations on mineral deposits in South Australia and to advise on geological aspects of exploitation—The Agent General and Trade Commissioner for South Australia, South Australia House, Marble Arch, London, W.1.

Assistant Experimental Officer (Chemist, male) for the Plant and Animal Products Department—The Establishment Officer, Imperial Institute, London, S.W.7.

Principal for Bury Technical College—The Director of Education, Education Offices, Bury.

Technicians (2) (Grade II) in the Department of Chemistry—The Secretary, University College, Gower Street, London, W.C.1, quoting Chemistry 5.

SCIENTIFIC RESEARCH AND MAN-POWER IN THE UNITED STATES

ALTHOUGH the two earlier reports on "Research—A National Resource", covering both the "Relation of the Federal Government to Research" and "Industrial Research", not to mention the more recent report from Dr. Vannevar Bush, "Science—the Endless Frontier", have to some extent prepared the British reader to appreciate the scale of the research effort in the United States—an effort in which it is estimated that 137,000 scientific workers were engaged in 1946–47, some 30,000 of them in government laboratories—it is not easy to convey a concise picture of the scope of the five reports which Mr. J. R. Steelman, chairman of the President's Scientific Research Board, has presented under the general title "Science and Public Policy"[*]. The White Paper on "Scientific Research and Development" issued in Britain is too slight to be comparable; possibly Sir John Anderson's descriptive survey of government organisation for research in his Messel Memorial Lecture last July is a more useful comparative outline of British activities. From the critical point of view, the penetrating analysis of expenditure on research and development contained in the third report of the Select Committee on Estimates for the session 1946–47 makes that report the appropriate British document to set beside the Steelman reports, although the latter also contain features in common with the White Paper on the Scientific Civil Service and with the report of the Barlow Committee on Scientific Man-power. However, nothing of quite the same scope and nothing comparable in scale has yet been published in Britain, although it is equally true that the whole subject has been discussed very thoroughly and fully as intensively, if not as quantitatively, in books and reports from both public and private sources as well as in Parliament.

The first of these volumes, entitled "A Program for the Nation", sketches the position of the United States in scientific research and development, comparing expenditure in 1930 and in 1945, and presents a budget for the future as well as discussing the limiting factor of man-power. After considering questions of personnel and the Federal organisation, it details recommendations for action by the Federal Government to meet the challenge of science and assure the maximum benefit to the nation. In the second volume, "The Federal Research Program", details of the Government's programme for research and development are analysed. The bulk of this volume consists of statements from the individual departments or agencies, indicating the range of work and its organisation; and among the appendixes is a useful note on definitions of research.

---

[*] Science and Public Policy. Vol. 1: A Program for the Nation. A Report to the President by John R. Steelman. Pp. x+73. 20 cents. Vol. 2: The Federal Research Program. By John R. Steelman. Pp. viii+318. 55 cents. Vol. 3: Administration and Research. By John R. Steelman. Pp. viii+324. 55 cents. Vol. 4: Manpower for Research. By John R. Steelman. Pp. viii+166. 35 cents. Vol. 5: The Nation's Medical Research. By John R. Steelman. Pp. x+118. 25 cents. (Washington, D.C.: Government Printing Office, 1947.)

The third volume, "Administration and Research", is concerned with the administrative problems that arise in the departments, bureaux and laboratories in executing the Government's programme, more particularly that part conducted in the Government's own laboratories. Questions of control and scientific freedom, the planning and evaluation of research activities, the 'climate' for research, and the methods of financing government research are discussed here, and recommendations for changes are made. In the fourth report, "Manpower for Research", the shortage of scientific workers and the implications of that shortage are discussed, including changes in distribution and their causes, and the action required for training more of them. The final report, "The Nation's Medical Research", discusses, first, the general problems of medical research, and next the Federal programme and its particular problems, indicating the content and distribution of research projects and describing the existing agencies and facilities for medical research.

Even this comprehensive survey, however, is not quite complete. In the first place, the social sciences are excluded, although some projects were examined in which both physical and social scientists were working. In the second place, the research programmes of the War and Navy Departments, apart from their medical programmes, were only examined very generally, because the Research and Development Board is making a detailed study of these programmes. Again, the delays in establishing the Atomic Energy Commission made impossible a detailed examination of the research programme of that Commission at the present time, apart from questions of national security. Nevertheless, sufficient investigations were made to judge the relation of these programmes to the scientific effort of the Government of the United States as a whole, and to provide a basis for administrative recommendations.

The first of these five reports is of the most general interest, to some extent summarizing the remaining four and detailing the general recommendations of the Scientific Research Board ; it is issued over the signature of its chairman, John R. Steelman. Moreover, side by side with the emphasis laid on research as the basis for an expanding economy and continued high levels of employment, as well as for progress in eliminating poverty and disease, there is in this report a remarkable emphasis laid on the importance of lending every possible aid to the re-establishment of scientific research and development in Europe. This emphasis is derived largely from the recognition that the strength of the United States has lain in the practical application of scientific principles rather than in original discoveries, and that further development must wait on the resumption of fundamental research which was everywhere largely in abeyance during the War.

The Steelman Report contends frankly that it is to the interest of the United States to make a maximum effort to restore the free exchange of ideas and the conditions of free international co-operation among men of science as it existed before the rise of totalitarian States, as well as to assist the reconstruction of the devastated countries of Europe an Asia. Such self-interest is no reason for looking askance at American generosity ; for it is equally t the national interest everywhere, as well as to tha of the progress of science, to re-establish the conditions in which the advance of science and th cross-fertilization of minds can again proceed freely across national frontiers. As the report observes the devastation of scientific work in Europe, th disruption of the normal international exchange o scientific knowledge and the suspension of fundamental work in important fields have altered ever premise upon which our thinking about scientifi research and development has been based.

This is the broad background against which th recommendations of the Steelman Reports have bee framed, and it is clear that they have been influence by very similar considerations to those which hav determined policy in Great Britain, given the difference in emphasis and development between fundamental and applied research in Britain as compare with the United States. They recommend first tha annual expenditure on research and developmen should be increased as rapidly as facilities and traine man-power can be expanded, so that, by 1957, a least one per cent of the national income, or mor than 2,000 million dollars, is devoted to research an development in the universities and industry an by the Government. Greater emphasis should b placed on fundamental research and medical research these expenditures should be quadrupled and triple respectively, in the next decade, while total researc and development expenditure is doubled. Feder support of fundamental research in the universiti and non-profit research institutions should be increased progressively to a level of at least 250 milli dollars by 1957. These figures look almost astronomical beside the estimates for Governme expenditure in Britain on research and developme of about 76·5 million pounds, the distribution which between fundamental and applied resear and between civil and military research was review by the Select Committee on Estimates in a repo for the session 1946–47. The Steelman Report m well observe that with so much public money alrea being spent in furtherance of research and develo ment, careful attention must necessarily be given the manner in which it is spent ; and while it is reco nized that the limiting factor at present is train man-power, a considerable amount of thought h been given to the way in which expenditure research should be controlled and distributed.

This is, of course, the kernel of the debate duri the last few years in the United States over a natio science foundation. There appears to be little disse from the view expressed in this report that at prese too small a proportion of the total resources of t United States is devoted to fundamental researc to health and medicine, and of its developme resources to non-military ends. The conflict opinion occurs over the means by which the balan of the research and development programme is to restored, and the manner in which Federal supp should be given.

The Steelman Report expresses the emphatic opinion that the bulk of the expansion in fundamental research must be in the universities and colleges, and be financed by Federal funds. For this purpose it recommends the establishment within the Executive Office of the President of a 'National Science Foundation', headed by a director appointed by the President and assisted by a part-time advisory board of scientific men and educationists, similarly appointed, half of whom should be drawn from outside the government service, and half from within. No restrictions should be placed upon the fields of inquiry eligible for support, and part of the funds expended by the Foundation should be used to strengthen promising colleges and universities.

The establishment of a national science foundation is not, however, in the view of the Science Research Board, all that is required. Some overall picture of the allocations of research and development functions among the Federal agencies, and of the relative emphasis placed upon fields of research and development within the Federal Government, must be available. Provision should also be made for a central point of liaison among the major research agencies to secure the maximum interchange of information with respect to the content of research and development programmes, and with respect to administrative techniques. At a single point close to the President, it should be possible to bring into the discussion of high policy the most significant problems in the research and development programme of the nation as a whole.

The idea of establishing a department of science to handle these functions was rejected, after consultation with scientific men and administrators, no doubt for similar reasons to those which have led to the rejection of the idea of a Ministry of Science in Great Britain. The Steelman Report recommends instead that a Federal committee be established, composed of the directors of the principal Federal research establishments, to assist in the co-ordination and development of the Government's own research and development programme. In addition, the Bureau of the Budget should set up a unit for reviewing Federal scientific research and development programmes, and the President should designate a member of the White House staff for scientific liaison. (This interdepartmental committee and scientific liaison officer have since been appointed.) Moreover, one of the first tasks of the interdepartmental committee would be a full analysis of the relative advantages of contracts and grants as a means of supporting research, and a careful review of the advantages arising from, and the problems connected with, the establishment of research co-ordinating bodies within large Federal agencies.

As already noted, the Scientific Research Board recognizes that the limiting factor in the expansion of research or development facilities is at present man-power; and, besides suggesting that the Federal Government, without making direct grants to industry, should encourage the expansion of industrial research by taxation incentives and other recognized methods, the Board points out that any programme of Federal assistance to the universities for research must be part of a broader programme of aid to higher education. Even a programme of scholarships or fellowships should not be established in the physical and biological sciences alone. The Board appears to lean to the support of fundamental research by grants rather than contract, and recommends that every Federal agency with major research responsibilities should have authority to make such grants, subject to the co-ordination by the suggested national science foundation. Furthermore, in time of peace, no secret or confidential research or development projects should, as a matter of policy, be placed with the universities; and the opinion of the Bush Report, "Science—the Endless Frontier", that complete freedom of inquiry must be preserved under any plan for government support of science is emphatically endorsed.

While the whole problem of university and college facilities was being examined independently by the President's Commission on Higher Education, the report of which has since been published, the Steelman Reports do not entirely pass by the question of university expansion. The section on "Manpower: the Limiting Resource", in this first report, points out that while between 1940 and 1947 United States expenditure on research and development increased by 335 per cent, the supply of trained man-power only increased by 35 per cent. It appears that the shortage of scientific man-power in the United States is even worse than in Britain, and particularly in the universities and colleges, where the urgently needed expansion of fundamental research is hampered, and there is danger that students will not receive the rigorous training required for such work. The report estimates that a further 15,000 instructors are required; but that there are enough students in the colleges and universities to double the supply of scientific workers within the next decade. Nevertheless, the balance in the research programme cannot be restored in the next year or two by expanding the programme for fundamental research or for non-military research and development without reducing expenditure on military or industrial research; and the Board, so far from being prepared to recommend such reduction, visualizes the possibility of having to increase research in the military sector.

On problems of personnel in science, the report says comparatively little, apart from stressing the importance of salary scales adequate to attract the ablest type of men, of associating the scientific worker with the formulation of policy, and of encouraging professional contacts. Appropriation by Congress of larger sums to enable scientific men in Federal service to travel to professional meetings is recommended, but the report is less searching in this respect than the Barlow report on scientific staff in Britain which was appended to the White Paper on "The Scientific Civil Service" in September 1945. The Select Committee on Estimates was also more penetrating in its report for the 1946–47 session already cited; but appended to the fourth volume of the series of Steelman Reports, "Manpower for Research", is a bibliography on scientific personnel, not confined to American publications, which is of considerable interest. A more comprehensive bibliography on the administration of research is appended to the third volume of the series.

Despite, therefore, the impressive scale of research effort in the United States, both existing and prospective, study of the Steelman Reports does not suggest that, on the whole, Great Britain has much to learn from the United States as regards the organisation of research. Indeed, Britain is free from certain difficulties which the federal system involves, and while it is clear that in both countries the risks and limitations of planning research are fully appreciated, even the Steelman Committee does not appear to be quite sure as to the means to be adopted for the control and organisation of fundamental research. Distrust of government interference goes far deeper in the United States than in Britain; but in considering medical research, the Committee does raise the question whether medical research for the Services could be pooled, and recommends the creation in the United States of an advisory Medical Research Committee for the large-scale, long-range planning of a national medical research policy.

There is thus much that is of interest to British scientific men in these five volumes, and from the immense assembly of facts, data can be selected to support arguments in favour of particular policies or action in Great Britain. The comments on the man-power situation, and especially the facts and observations presented in the appendix to the fourth volume, "Manpower for Research", deserve careful study. When the Scientific Research Board appointed by the President of the United States takes such a wide view, and can still urge generous help towards the reconstruction of scientific institutions in Europe, it is worth remembering that the progress of science in Britain is equally dependent upon the re-establishment of a world community of science.

The Steelman Reports express the view that it is essential that the aid to be given to the research laboratories of Europe should be on terms which ensure the maximum contribution towards the restoration of pre-war conditions of the free exchange of scientific knowledge across national frontiers. The assistance contemplated is not limited to actual reconstruction; it includes encouragement for students from abroad to attend American universities and colleges, as well as the establishment of scientific missions abroad. The solidarity of British and American opinion in such matters as these, the clear recognition that, in the long run, science cannot flourish in the midst of a troubled world, the insistence on those cherished freedoms of expression and association which are the corner-stones of democracy, as they are conditions of scientific advance, are among the most welcome and outstanding features of these reports. For British readers they carry the corollary that our own efforts to foster international exchange of knowledge and understanding must be no less determined, positive and even sacrificial, in the hope that the two great democracies may work together for the good of the whole world.

PLANT LIFE IN BRITAIN

British Plant Life

By Dr. W. B. Turrill. (New Naturalist Series.) Pp. xvii + 315 + 72 plates. (London and Glasgow: Wm. Collins, Sons and Co., Ltd., 1948.) 21*s.* net.

So far as coloured illustrations are concerned, this most recent addition to the "New Naturalist" series is probably the most successful. They consist of fifty-three colour photographs by John Markham, Brian Perkins, F. Ballard and others. The close-up photographs of yew, black bryony and hawthorn in fruit and the ground pine in flower are excellent: that of the fleabane is not so good, the foliage being badly blurred and the flower-heads not very distinct. Moreover, the colour of the close-up of fritillaries has registered rather badly. Perhaps the most beautiful of all the plates is that of bluebells. Among the more distant views attention should be directed to that depicting heather in the fore- and middle-grounds with Scots pine in the background, and that depicting dandelions.

Great care has obviously been taken in the choice of black-and-white photographs by such well-known Nature photographers as John Markham, Eric Hosking, Brian Perkins, Robert Adam, Anne Jackson, etc.

Among the maps are one showing the botanical vice-counties of Great Britain and Ireland, and eight others illustrating the distribution of certain selected species of plant, from the hazel (*Coryllus avellana*), which necessitates shading the map of the entire islands, to the Cheddar pink (*Dianthus cœsius*), represented only by a small shaded patch in Somerset. (Is Cheddar deliberately spelt with a lower case 'c' on the map, following the strange modern craze? If so, then the same style should have been followed in the text on p. 54.)

The aforementioned characteristics of this book will have an immediate appeal to both amateur and professional botanist, for all are excellent. But there is much more in the book than this, namely, the text, written by one of Britain's leading authorities who is keeper of the Herbarium and Library at the Royal Botanic Gardens, Kew.

In no sense is the book a Flora; it is an erudite review of the wild vegetation made from those angles with which other research botanists have come to associate the name of Dr. W. B. Turrill.

Following an introductory chapter are four dealing with the vicissitudes to which the British flora has been subjected before attaining its present composition. From the origin of life itself we come to the beginnings of plant life, and are then led up to the very important changes induced during the Ice Age and the further changes which occurred during the Post-glacial Epoch. In the last-named, the most up-to-date methods of pollen analysis and the conclusions drawn from these studies are presented in a very clear manner.

In the review of the present position of the British flora we learn that there are about 1,500 seed-bearing plants, and a very useful list is given of 91 plant families together with the number of genera and species which constitute each, from Compositæ, containing 42 genera and 114 species, to families containing only one species, such as Cucurbitaceæ—*Bryonia dioica* (white bryony); Loranthaceæ—*Viscum album* (mistletoe), etc.

From then on, the author leads up, through geographical relationships, to an up-to-date study o plant ecology, beginning with habitat factors, namely, climatic, edaphic and biotic. Then a long chapter deals with the different kinds of plant communities. Here Dr. Turrill takes full advantage of the great strides which have recently been made in ecological research, especially in Great Britain.

A study to which the author has made important research contributions is that of variation in plants, and in a chapter of 20 pages he waxes lucid and eloquent on the subject.

Adaptation, natural selection and heredity certainly have an important part to play, especially in such a comparatively crowded flora as that of Britain, and n this book these phenomena are well presented and illustrated with many carefully chosen and clear examples. This implies that the flora of these islands, ike that of many other parts, is still undergoing changes, so the author does well to consider them; for students so frequently fail to realize that though this age is experiencing the 'traditions' of the past, it is also contributing new 'traditions' for the future.

At the end of the text, a fairly full, but not indigestible, bibliography, a useful glossary and an index are appended.

"British Plant Life" has been carefully conceived and well written. It is difficult to imagine who would not benefit by reading it, for it is indeed readable; we would strongly recommend it to all academic students of botany and to the many more amateur naturalists who are making flowering plant life their special line. Not only will they see and read with nterest and enjoyment; but also they can put implicit trust in the factual material.

This is a book worthy of the author so far as text is concerned, a credit to the photographers who have contributed the illustrations and a title which will enhance the reputation of the publishers who are producing this excellent series of books.

L. J. F. BRIMBLE

EVERYTHING ABOUT THE DOG

The Book of the Dog

Edited by Brian Vesey-Fitzgerald. Pp. xviii + 1039 + 24 plates. (London: Ivor Nicholson and Watson, Ltd., 1948.) 42*s*. net.

TO begin with, one must commend the majestic appearance of this in every sense weighty volume —a worthy companion to the same combination's production, "The Book of the Horse". It is stimulating to handle a thing of substance and quality in these attenuated days. At two guineas it is good alue, and here, in material content, is what you et for it: 1,057 quarto pages of good paper, and honest-sized type; 336 illustrations, including twenty-four excellently produced coloured plates; full description and illustration of 119 breeds of dogs; forty-one articles covering practically every aspect of the dog and man's relations with it—at all events I cannot think of any more, except possibly circus dogs, an omission I for one can endure without complaint; all this done by sixty-two contributors, who in this review must mostly remain anonymous, though they are all experts in their own subject. The quantity of material is impressive; so also is the quality, chiefly, because, although a high literary standard was obviously not the target of the planner, yet, notwithstanding the total length of the book, the individual articles are generally concise, factual and clear. There is, too, a general absence of sentimentality—though lots of affection—which is most refreshing.

One of the most interesting and informative passages in the whole book is Dr. Vevers' section on worms, which forms part of his opening chapter on "The Phylogeny, Domestication and Bionomics of the Dog". The things that can go on inside a dog as the result of entertaining these parasites are not to be lightly dismissed with worm powders, and the average casual dog owner needs considerable education in this matter, if one is to judge from the general condition of the dogs one sees about. While on this subject I endorse the condemnation by R. C. G. Hancock ("Nursing and Treatment") of the amateur 'vet.'. The records of such bodies as the P.D.S.A. are witness to the immense suffering caused to dogs, and indeed all domestic animals, by ill-advised amateur attempts at treatment. The reasons for this seem to be twofold: pride—everybody likes to be considered knowledgeable on something he knows nothing about; and meanness—the number of people who will go to almost any length to avoid parting with money to a 'vet.' is positively scandalous. This is very prevalent also among amateur horse owners.

Dr. Vevers gives interesting comparisons between the dog and the cat. A theme I would like to see developed more fully is the extreme psychological divergence of the dog and the cat, which may or may not have something to do with what one might call the physical malleability of the former. Man has moulded the dog into an astonishing variety of shapes and sizes according to his moods and needs; but he has never been able to do anything with that intractable creature the cat; and, while the dog has always worshipped man, man did at one time worship the cat.

Like the horse, the dog appears first in history in pictures, usually in hunting scenes; so Mr. Croxton Smith infers reasonably enough that a very early use of dogs by man was for hunting and tracking other animals—in slight contradiction to the authorities quoted by Dr. Vevers, who suggest that scavenging was the first occupation of the friend of man *qua* friend. From my own experience of 'pi-dogs' in the East I would say that scavenging, though no doubt useful, was not the way the dog took to man's heart. The truth, however, seems to be that we know very little about the matter until we come to the pictures, the first historical record. After that it does not seem to have been long before man began to grow sentimental about the dog, and so he has remained to this day. The chapter on "The Dog in History" is particularly well done. So, too, are the other sections on working dogs, in the shooting and hunting fields, in sheep herding, in which we see the dog at his best, in guiding the blind, and in war. An omission in the latter, in passing, is mention of the training of war and police dogs in the U.S.S.R. They were trained, I believe, to attack and destroy tanks and themselves—by leaping at them with detonating charges on their backs.

John Board writes comprehensively and chattily on "Selecting a Breed", though, so impartial is he in once sense and so partial to all sorts of dogs in another, it would be difficult at the end to resist getting them all. But we are all mostly prejudiced in favour of the last dog we have owned, so I will express my own partiality and recommend my favourite, the Sydney Silky—who receives scant attention in the breed section—one of the gamest, most intelligent and lovable of all terriers, and one still unspoilt by the attentions of exhibitors.

It would be possible to go on browsing indefinitely and happily through the pages of this book. There is so much that could be mentioned: the dog in art, in literature, foxhounds, greyhounds, the Samoyed, the Kennel Club and Crufts, the excellent chapters on breeding, training, and showing, and not omitting a scholarly and scientific dissertation on that canine outcast, the pariah—though I cannot share the anxiety of the Menzels for its preservation. It must be left to others to dig in this canine mine with the certainty that they will extract both pleasure and profit from it.

C. E. G. Hope

THE FREE ELECTRON *IN VACUO*

Vacuum Tubes

By Prof. Karl R. Spangenberg. (McGraw-Hill Electrical and Electronic Engineering Series.) Pp. xvii + 860. (New York and London: McGraw-Hill Book Co., Inc., 1948.) 45*s*.

FOR many years the literature of applied physics has lacked a really up-to-date and complete account of the phenomena occurring inside valves. In consequence, students are taught very little about them, a sad contrast with the attention paid to circuit applications. To fill this void, Prof. K. R. Spangenberg has written the present bulky volume, addressed mainly to senior and graduate students, but with the needs of research workers kept in mind. The book begins with the basic physics of the subject: atomic theory, electron emission, electrostatics and the dynamics of charged particles. Potential theory is next discussed, with detailed application to triode and multigrid valves. After a brief consideration of shot effect and resistance noise, a section of 142 pages is devoted to electron optics and the cathode ray tube. Transit-time effects come next, and lead to the elementary theory of velocity modulation valves and cavity magnetrons. Then there are chapters on photo-electric devices and various special tubes, while the final chapter of sixty pages gives a résumé of high-vacuum practice, based on material supplied by C. V. Litton. Some mathematical topics, units, skin effect and Langmuir's diode tables are discussed in appendixes.

This synopsis shows the planning of the book to be logical and comprehensive. Unluckily, the execution is not up to the level of the plan, for the treatment is very uneven in depth and precision. From the point of view of the student, it is particularly unfortunate that the sections on the physical phenomena are the poorest in the book. There is only the most sketchy account of the preparation of oxide cathodes, photo surfaces, fluorescent screens and many other matters essential for the preparation of the simplest valve. On the theoretical side these sections are equally weak. For example, the oxide cathode is not discussed as a semi-conductor, and there is no attempt to derive Richardson's law for a pure metal.

The unfavourable impression made by the first few chapters is largely dispelled by the competent handling of the theory of triodes, tetrodes and pentodes, both as potential problems and in the space charge régime. Prof. Spangenberg has made original contributions to some of the questions discussed here, and on electron optical theory, so it is natural that these should be the best parts of the book. The discussion of transit-time valves is clear and correct so far as it goes; but, considering that nearly two hundred pages are used, this is not far. Some original work on velocity-modulation tubes to cover a frequency-band of more than an octave is, however, included.

A peculiarity of the book is that all the more important expressions are given as nomograms. While this device does give a very clear idea of the magnitudes involved, the accuracy is limited by the page size to a value lower than that of even a six-inch slide rule.

It is to be hoped that, in a second edition, Prof. Spangenberg will divide the work into two separate parts, a students' text-book, and a definitive reference handbook for specialists. This would reduce the bulk of the material sufficiently to allow it to be handled in a university course. In its present form the book, while welcome, will disappoint the more sophisticated readers.

A. H. Beck

PHYSICAL PROPERTIES OF RUBBER

Le caoutchouc

Matériau de construction. Par l'Institut français du caoutchouc. Avec le concours de Georges Colin, André Jarrijon et Pierre Thirion. (Etudes de synthèse et de documentation l'Actualité technique.) Pp. viii + 230. (Paris: Libr. Dunod, 1947.) 560 francs.

ALTHOUGH the remarkable physical properties exhibited by rubber are such as to commend its use for certain specialized engineering applications, it has not been easy for designers to obtain reliable quantitative information upon which to base their work. The volume under review goes some considerable way to filling the need felt by the designer for a comprehensive account of the physical attributes of rubber. The reluctance of the rubber technologist to commit himself to figures in describing the properties of this remarkable substance has been due partly to the fact that the word rubber covers materials having a tremendous range of properties. The width of this range is, indeed, indicated by the authors, although it is felt that in some sections figures are presented without sufficient emphasis on the fact that they are typical only of the compounds of particular manufacturers.

The volume includes a short account of the theories of the rubber-like state, a similar amount of space devoted to industrial processing technique, a thorough review of physical properties and finally a section giving details of the various applications of rubber, including methods of calculation. The balance as between these sections is good in view of the needs of the intended reader. There are a few errors in figures, the most serious in Table V, p. 44, where figures for internal friction are too large by a factor of 10^3.

It is a matter for regret that a book such as this to which frequent reference will be made, should be bound inadequately in paper covers which cannot stand up to a week's careful handling by the reviewer.

W. P. Fletcher

Everyman's Mathematics

By F. G. Brown. Pp. xix+748. (Sydney and London: Angus and Robertson, Ltd., 1947.) 36*s*.

AFTER fifty years of teaching in primary and secondary schools, teachers' training colleges, adult classes, and the Royal Australian Naval College, Mr. Brown is very much dissatisfied with the usual methods of teaching elementary mathematics. He considers that the few basic principles are clouded and hidden by an over-elaboration of the details, and that much time is wasted in doing too much in the wrong way. He has therefore prepared a treatment which, though mainly an attempt to interest the adult who has forgotten what he learned at school, also suggests, in the first half of the book, the minimum amount of mathematics which a school might be expected to teach to boys and girls of fifteen years of age. This part deals with arithmetic (based almost entirely on the "method of Rates"), geometry, algebra and trigonometry. The second half of the book illustrates the type of material suitable for use in an adult education study-group; it lays stress on applications to instalment systems, depreciation, decibels and phons, dynamic design, fallacies and puzzles, as well as on more conventional branches of mathematics such as graphs and calculus.

Both parts of the book are written in amusing and colloquial language, with anecdotes, historical references, and digressions, some of which throw more light on the author's opinions on things in general than on mathematics. There are many examples for solution, and the answers are given at the end of the book, in some cases with hints how to obtain them. There is a full index.

Any portion of the book, taken by itself, is very readable; but taken altogether, there is too much of everything. The publishers' claim that the book is for every man and woman raises two questions. Is every man prepared to read such a large book (more than 750 pages), and if so, is he prepared to pay 36*s*. for it? H. T. H. PIAGGIO

Plasticity in Engineering

By F. K. Th. van Iterson. Pp. ix+174. (London, Glasgow and Bombay: Blackie and Son, Ltd., 1947.) 8*s*. 6*d*. net.

AS the author rightly claims in the preface, the chief reason for writing a book on the theory of plasticity is to direct attention to its importance—from the engineering point of view equal to that of the theory of elasticity. Nevertheless, to be of real value, such a book must review the state of knowledge of the subject as a whole, or, on a smaller scale, provide an introduction to the subject, dealing only with well-established theoretical and experimental results.

This book fulfils neither function adequately, and is correspondingly of limited value to the research worker and of real danger to the student. The author has instead developed in it a group of theoretical results, which are neither based on an adequate consideration of the theoretical background, nor supported by convincing experimental evidence; in this connexion, the author has had access to a considerable field of Dutch work, but unfortunately gives only very abbreviated accounts of it. American work, other than the edition in English of Nadai's famous book, is covered in four brief references, and it is unfortunate that the author has apparently not been aware of the important work being done in Great Britain. In the past eighteen months, for example, a collection of papers has been published by R. Hill and fellow-workers, which involve conclusions very different from many of those described.

The valuable features are a considerable collection of recent references, scattered through the book, to Continental work, some illuminating introductory chapters on fundamental aspects of the subject, and a few interesting photographs and diagrams relating to observed results. G. D. S. MACLELLAN

Flowering Earth

By Donald Culross Peattie. Pp. vii+200. (London: Phœnix House, Ltd., 1948.) 10*s*. 6*d*. net.

THIS book is an unusual introduction to the study and appreciation of plant life. The theme running through it is the unity—more particularly in a symbiotic sense—of all living organisms. It is very clearly shown that plants with chlorophyll are basic to the existence of all living organisms, except a few "bacterial autotrophs". Hence, "we ought not to speak of getting at the root of a matter, but of going back to the leaf of things". The main groups and functions of plants are considered in extremely simple language and with the use of a minimum of technical terms.

The opinion may be expressed that a majority of the persons to whom this book might appeal would prefer a little more 'meat' in the eighteen chapters. On the whole, the statements concerning plants are accurate and up to date; but some corrections are necessary. The number of species of flowering plants is stated on p. 124 to be "some one hundred thousand", while on p. 152 "two hundred thousand species" of Angiosperms are said to "populate our flowering world". Kerguelen was certainly visited by Sir Joseph Hooker, but this island is usually considered as being in the southern part of the Indian Ocean and not in the Pacific. It is unfortunate that the desire for simplification of language has led to the use of such phrases as "tiny acids" and to the manufacture of such a plural as "algas". The author is obviously a sincere lover of plants and many of his philosophical ideas are admirably expressed.

W. B. TURRILL

Royal Society Empire Scientific Conference, June–July 1946

Report. Vol. 1. Pp. 828. Vol. 2. Pp. 707. (London: Royal Society, 1948.) 2 vols., 42*s*. net.

THE Report of the Royal Society Empire Scientific Conference, June–July 1946, now issued in two handsome volumes, includes the speeches at the opening ceremony, the papers presented, and recommendations and notes on the discussions (see also *Nature*, July 27, 1946, p. 136). In addition to the "Notes on Current Scientific Researches in the United Kingdom" prepared by the Royal Society, various papers on the organisation of scientific research in the Colonies, in Canada, India, New Zealand, South Africa and Southern Rhodesia give a very useful conspectus of the organisation of such research throughout the British Commonwealth of Nations. The volumes are admirably indexed, and the immense amount of information they contain is made accessible to the reader in a way worthy of the Royal Society and setting a standard that might well be followed widely. They constitute both a worthy record and a reference work on scientific research, information services and related topics in the Empire that should be valuable for several years to come.

R. B.

THE EVOLUTION OF THE UNIVERSE

By DR. G. GAMOW
George Washington University, Washington, D.C.

THE discovery of the red shift in the spectra of distant stellar galaxies revealed the important fact that our universe is in the state of uniform expansion, and raised an interesting question as to whether the present features of the universe could be understood as the result of its evolutionary development, which must have started a few thousand million years ago from a homogeneous state of extremely high density and temperature. We conclude first of all that the relative abundances of various atomic species (which were found to be essentially the same all over the observed region of the universe) must represent the most ancient archæological document pertaining to the history of the universe. These abundances must have been established during the earliest stages of expansion when the temperature of the primordial matter was still sufficiently high to permit nuclear transformations to run through the entire range of chemical elements. It is also interesting to notice that the observed relative amounts of natural radioactive elements suggest that their nuclei must have been formed (presumably along with all other stable nuclei) rather soon after the beginning of the universal expansion. In fact, we notice that natural radioactive isotopes with the decay periods of many thousand million years (such as uranium-238, thorium-232 and samarium-148) are comparatively abundant, whereas those with decay periods measuring only several hundred million years are extremely rare (as uranium-235 and potassium-40). If, using the known decay periods and natural abundances of these isotopes, we try to calculate the date when they have been about as abundant as the corresponding isotopes of longer life, we find that it must have been a few thousand million years ago, in general agreement with the astronomically determined age of the universe.

The early attempts to explain the observed relative abundances of the elements[1,2] were based on the assumption that the present distribution represents a 'frozen equilibrium state' corresponding to some very high temperature and density in an early stage of universal expansion. Such equilibrium theories lead, however, to the result that the logarithm of the relative abundance must be a linear function of the nuclear binding energy, which in its turn is known to be a linear function of atomic weight. Thus, according to that picture, we would expect a rapid exponential decrease of relative abundances all the way from hydrogen to uranium, in direct contradiction to the observed distribution, (circles in Fig. 1), which shows a rapid decrease for the first half of the natural sequence of elements, but levels up almost to a constant value in the second half.

As the result of this difficulty, I suggested[3] that the observed abundances do not correspond to any equilibrium state at all, but, quite on the contrary, represent a dynamical building-up process which was arrested in a certain stage of its development by a rapid expansion of the universe. According to this point of view, one should imagine the original state of matter as a very dense over-heated neutron gas which could have originated (if one lets one's imagination fly beyond any limit) as the result of hypothetical universal collapse preceding the present expansion. In fact, the extremely high pressures obtaining near the point of complete collapse (singular point at $t = 0$) would have squeezed the free electrons into the protons, turning the matter into the state of over-heated neutron fluid. When the expansion began, and the density of neutron gas dropped, the neutrons would be expected to begin decaying again into protons, and more and more complex nuclear aggregates could be built up as the result of the union between the newly formed protons and the neutrons still remaining. Such a building-up process must have started when the temperature of the neutron–proton mixture dropped below a few times 10^{10} °K., which corresponds to the mutual binding energies of these nuclear particles. The equations governing such a gradual building-up process can evidently be written in the form:

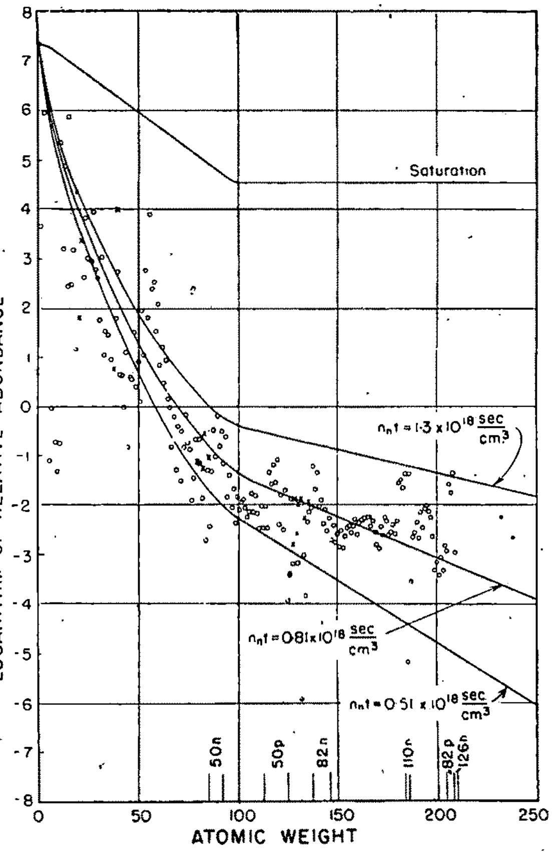

Fig. 1

$$\frac{dn_i}{dt} = \lambda_{i-1}\, n_{i-1} - \lambda_i\, n_i \quad (i = 1, 2, 3, \ldots), \quad (1)$$

where n_i is the number of atomic nuclei of atomic weight i, and λ's are the coefficients depending on the collision frequency, and the capture cross-sections for fast neutrons in the nuclei of various atomic weight.

The numerical study of these equations was carried out by R. Alpher[4,5], who used the recent experimental data on the capture cross-sections of fast neutrons. These cross-sections are known to increase very rapidly by a factor of several hundred for the first half of the atomic weights, and to remain more or less constant for the second half; a fact which is of paramount importance for understanding the general shape of the abundance curve. Suppose that the building-up process goes at a constant density, ρ, for a limited period of time, Δt; the resulting abundances will depend apparently only on the product $\rho\Delta t$, which determines the total number of collisions between the developing nucleus and the free neutrons.

The results of the computations carried out by R. Alpher are shown by continuous curves in Fig. 1, with the values of $n_n \Delta t = \frac{\rho}{m} \Delta t$ marked on each curve. It is seen that for very large values of $n_n \Delta t$, the process reaches saturation, and the number of the various nuclei becomes inversely proportional to the corresponding capture cross-sections. For smaller values of $n_n \Delta t$, heavier nuclei do not have time to build up to the saturation point, and we see from the figure that for $\rho \Delta t \cong 1{\cdot}3 \times 10^{-6}$ gm. cm.$^{-3}$ sec. ($n_n \Delta t \cong 0{\cdot}8 \times 10^{18}$ sec. cm.$^{-3}$) the calculated curve stands in very good agreement with the observational data.

The agreement obtained is amplified by the fact that the observed abundances show the abnormally high values for the isotopes containing the completed shells of neutrons or protons (as indicated along the atomic weight axis in Fig. 1); in fact, it is known that such nuclei possess abnormally small capture cross-sections, which would cause the accumulation of the material at these particular atomic weights. Since the building-up process must have been accomplished within a time period comparable with the decay period of neutrons, we have $\Delta t \cong 30$ min. $\cong 2 \times 10^3$ sec., from which it follows that during that period the density of matter must have been of the order of magnitude 10^{-9} gm. cm.$^{-3}$. On the other hand, since the temperature must have been of the order of 10^9 °K., the mass-density of radiation, aT^4/c^2, was comparable with the density of water. Thus we come to the important conclusion that, at that time, the expansion of the universe was governed entirely by radiation and not by matter.

In this case the relativistic formula for the expansion can be written in the form[6],

$$dl/dt = \sqrt{\frac{8\pi G}{3} \frac{aT^4}{c^2} l^2}, \tag{2}$$

where l is an arbitrary distance in the expanding space, and the constant term containing the radius of curvature is neglected because of the high value of the density. Remembering that for the adiabatic expansion of the radiation $T \sim 1/l$, we can integrate (2) into the form:

$$T = \sqrt[4]{\frac{3c^2}{32\pi Ga}} \cdot \frac{1}{t^{1/2}} = \frac{2{\cdot}14 \times 10^{10}}{t^{1/2}} \text{ °K.} \tag{3}$$

For the mass-density of radiation we have:

$$\rho_{\text{rad.}} = \frac{3}{32\pi G} \cdot \frac{1}{t^2} = \frac{4{\cdot}5 \times 10^5}{t^2} \text{ gm.cm.}^{-3}. \tag{4}$$

For the density of matter we must evidently write:

$$\rho_{\text{mat.}} = \frac{\rho_0}{t^{3/2}} \text{ gm.cm.}^{-3}, \tag{5}$$

where ρ_0 is to be determined from the conditions of the nuclear building-up process. It can be done in the simplest way by considering the building up of deuterons by proton–neutron collisions. Writing X for the concentration of neutrons (with $X(0) = 1$); and Y for the concentration of protons (with $Y(0) = 0$), we obtain the equations:

$$\begin{aligned} \frac{dX}{dt} &= -\lambda X - \frac{XY}{m}\rho v\sigma, \\ \frac{dY}{dt} &= +\lambda X - \frac{XY}{m}\rho v\sigma, \end{aligned} \tag{6}$$

where v is the thermal velocity, and σ the capture cross-section which (for the energies in question) can be sufficiently accurately represented by the formula[7]:

$$\sigma = \frac{2^{3/2}\pi e^2 \hbar \varepsilon^{5/4}}{m^3 c^5} \cdot \frac{1}{E^{3/2}}, \tag{7}$$

$\varepsilon = 2{\cdot}19$ MeV. being the binding energy of the deuteron. Expressing v and E through the temperature, and using (3), we can rewrite (6) as:

$$\begin{aligned} \frac{dX}{d\tau} &= -X - \frac{\alpha XY}{\tau}, \\ \frac{dY}{d\tau} &= +X - \frac{\alpha XY}{\tau}, \end{aligned} \tag{8}$$

where $\tau = \lambda t$ and:

$$\alpha = \frac{2^{13/2}\pi^{5/4} e^2 \hbar \varepsilon^{5/2} G^{1/4} a^{1/4}}{3^{5/2} m^{9/2} c^{11/2} k} \cdot \rho_0. \tag{9}$$

In order that the equations (8) should yield $Y \cong 0{\cdot}5$ for $\tau \to \infty$ (since hydrogen is known to form about 50 per cent of all matter), the coefficient α must be set equal to 0·5. The change of X and Y with time in this case is shown in Fig. 2, which also indicates the corresponding variation of temperature. Assuming $\alpha = 0{\cdot}5$, we find from equation (9) that $\rho_0 = 0{\cdot}72 \times 10^{-3}$, which fixes the dependence of material density on the age of the universe.

Once we have $\rho_{\text{rad.}}$ and $\rho_{\text{mat.}}$ as functions of time, we can follow the physical processes taking place during the further expansion of the universe, and in particular calculate the masses and sizes of the con-

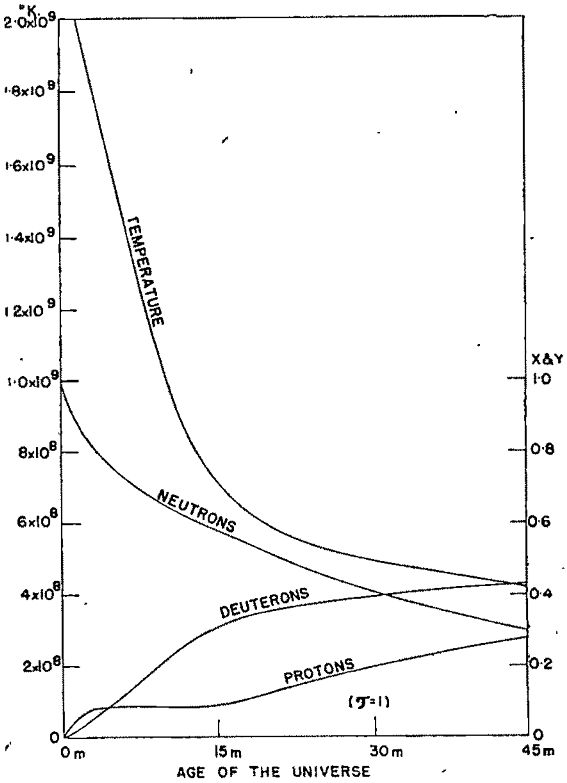

Fig. 2

densations of that primordial gas which must have originated sooner or later according to Jeans' principle of gravitational instability[8]. Jeans' classical formula gives the diameter D of the condensations which will be formed in a gas of temperature T and density ρ in the form:

$$D^2 = \frac{10\pi}{9mG\rho} \cdot \frac{3}{2} kT. \qquad (10)$$

Using the expressions (3) and (5), we get:

$$M = \rho D^3 = \frac{2^{31/8} 5^{7/4} \pi^{5/4} e \hbar^{5/4} \varepsilon^{5/4}}{3^{17/8} m^{15/4} c^{5/4} G^{7/4}} \qquad (11)$$

(where a has been expressed through other fundamental constants).

It is interesting to notice that the time-factor cancels out in the calculation of M, so that the mass of the condensations comes out the same, independent of the epoch when they were formed. It seems, however, reasonable to assume that the effect of gravitational instability became important only when the mass-density of radiation became comparable with the density of matter, since it is hard to imagine a 'gravitational condensation of pure radiation'. Using (4) and (5), we find that $\rho_{\text{rad.}} = \rho_{\text{mat.}} = 3 \times 10^{-26}$ gm.cm.$^{-3}$ at $t = 3 \cdot 9 \times 10^{15}$ sec. $= 1 \cdot 3 \times 10^8$ years, at which point $T = 340°$ K. For this value of t we obtain:

$$D = \frac{2^{45/8} 5^{1/4} \pi^{7/4} e^3 \hbar^{3/4} \varepsilon^{15/4}}{3^{27/8} m^{29/4} c^{35/4} G^{5/4}}. \qquad (12)$$

Substituting numerical values, we have:

$$\begin{aligned} M &= 5 \cdot 5 \times 10^{40} \text{ gm.} = 2 \cdot 7 \times 10^7 \text{ sun-masses} \\ D &= 1 \cdot 3 \times 10^{23} \text{ cm.} = 13{,}000 \text{ light-years,} \end{aligned} \qquad (13)$$

which must represent the masses and the diameters of the original galaxies.

The above estimate of galactic masses falls short by a factor of about one hundred from the mass-values of galaxies obtained from astronomical data. But it must be remembered that the simple Jeans' formula used in these calculations does not take into account the effect of radiation pressure, and also is applicable only to the gravitational condensations in non-expanding space. The effect of additional radiation pressure (which is quite important according to the previous considerations) and the tearing force of expansion will lead to considerably larger condensation masses. The detailed study of this question will require, however, the extension of Jeans' classical arguments for the case of a mixture of gas and radiation in the expanding space. At the present stage one should be satisfied with the fact that, by such comparatively simple and rather natural considerations, *masses and sizes comparable to those of stellar galaxies can be expressed in terms of fundamental constants, and the basic quantities of nuclear physics.*

We may add that, according to the above picture, the galaxies have been originally formed in the purely gaseous form (including a certain amount of solid dust particles), which must account for the regular shapes of rotating bodies. The formation of individual stars within the galactic bodies must have taken place at a somewhat later stage, probably along the lines of the Spitzer – Whipple theories[9,10]. When stars were formed by the condensation process within the rotating gaseous mass, their tangential velocities, being equal to the original velocities of the gas-masses, were clearly not high enough to maintain them on circular Kepler orbits, so that *the newly formed stars must have been moving along elongated elliptical orbits with the points of maximum elongation in the places of their origin.* This situation must have remained essentially unchanged even when all the material of originally gaseous galaxies was used up in the formation of stars.

These considerations give a simple explanation of the otherwise mysterious fact that the elliptical galaxies and the central bodies of spirals rotate 'as solid bodies' with the linear velocities proportional to the distance from the axis. In fact, according to our picture, the maximum Doppler displacements observed at various distances from the axis correspond to the velocities of stars passing through 'aphelion' at these particular distances, and, according to the previous argument, are equal to the velocities which the gas-masses must have had in these regions prior to their condensation into the stars.

COASTAL WAVES*

RECENT investigations by the Admiralty have shown that storm waves and the swell that leaves the storm area are composed of a mixture of wave-trains, the wave-lengths of which range from a few feet up to a maximum which depends on the greatest wind strength, and may be as much as 3,000 feet. It seems remarkable that such component wave-trains should travel independently across the ocean, and that all except the very shortest should be recognizable after travelling thousands of miles; but such close agreement with theory has been demonstrated, and the component wave-trains have been found to advance across the ocean with the theoretical velocities appropriate to their lengths.

The short waves formed at the beginning of a storm are overtaken and outdistanced by long waves formed when the wind is strongest. With the help of new wave-recording and analysing apparatus, each wave-length can be detected and its amplitude measured when it arrives at a distant coast, and the waves recorded on the coast of Cornwall are found at times to be a mixture of waves generated near the coast with swell-components from more than one North Atlantic storm, and with other swell, probably a few inches high, which was generated in a storm so far away as Cape Horn.

The visible crests and troughs are the result of the combination of trains of waves of different lengths, and since such waves travel with different velocities, the wave-pattern is continually changing. When some of the component wave-trains get into step and reinforce each other, they produce a group of typical waves with relatively high crests and deep troughs; but, when they get out of step and tend to neutralize each other, the wave-crests are low and irregular. Such interaction between component wave-trains explains the recurrence of sequences of high and low waves that is often observed; it is not necessarily the fifth, seventh or any other number of wave that is always the highest, but there is often sufficient regularity to suggest a rhythm, and to allow the coxswain of a boat to take advantage of one of the quiet periods. There is most likely to be a noticeable rhythm when a narrow range of wave-lengths is present, as in long swell from a distant storm. Although the variability of the wave-pattern on deep water and of the height of the crests that approach the beach depends on the interaction of component wave-trains, such interaction appears to be suspended when the waves reach very shallow water; here they rise into sharp crests separated by wide, flat troughs, and each crest seems to travel independently of its neighbours.

---

* An account of the symposium held at the meeting of Section A (Mathematics and Physics) of the British Association on September 9, in which Brigadier R. A. Bagnold, Mr. N. F. Barber, Dr. G. E. R. Deacon and Major W. W. Williams took part.

One of the most noticeable changes in waves entering shallow water is an increase in height. The reason, according to an explanation given by Lord Rayleigh in 1911, is essentially that the velocity of a wave decreases as the depth of water decreases, and the height of the wave increases since it must carry energy towards the shore at the same rate. The increase in height depends on the wave-length, and long swell may rise to as much as twice its deep-water height; it may become apparent for the first time when it enters shallow water, and such an emergence has earned for it the name 'ground-swell'.

When waves approach the shore obliquely, the ends which reach shallow soundings first travel slower than the seaward ends, and the waves swing round until they are nearly parallel to the beach. In this way waves can swing round headlands and islands, and enter bays not directly exposed to their original direction; the effect is more marked with long waves, and a long swell may round a headland that offers complete protection against shorter wind-waves. A shallow spit extending out to sea tends to focus the wave-energy; but a deep gulley pointing into shallow water causes the wave-energy to be refracted towards the sides and offers quieter water in the middle. Waves are also affected by tidal streams, and Mr. N. F. Barber argued that waves travelling at 20 knots in still water would make no progress against a tidal stream of 5 knots but would steepen and break. Waves meeting a tidal stream obliquely will be refracted, and the theory suggests that a tidal stream may protect an anchorage.

Brigadier R. A. Bagnold, dealing with the movement of sand and shingle, described model experiments in which it could be seen that long waves approaching a beach give rise to a strong drift of water along the bottom in the direction of wave travel; this movement is continued as far as the plunge-line, where the waves break, and there the water appears to rise from the bottom to form a backward drift at the surface. He remarked that we have no exact knowledge of what happens on the bed of the sea, although it is of great importance to engineers to predict the movements of sand and shingle; the necessary observations on the sea bed would be difficult and expensive, but it is quite possible to make them.

Mr. Barber put forward theoretical reasons for believing that the movements in the sea would resemble those observed in the model. Waves cause a small transport of water in their direction of travel, greatest at the surface but almost as large at the bottom if the waves are long. It is not likely to be affected to any appreciable extent by friction with the bottom, since the vorticity associated with the oscillatory movements of the waves is continually changing sign and therefore unable to diffuse far above the bottom. The seaward drift which must compensate for the shoreward transport can, on the contrary, be treated as a unidirectional flow for which the effect of the bottom drag will be greater, and its velocity will be a maximum at the surface and zero at the bottom. The resultant effect of bottom friction and viscosity on the wave-transport and the compensating seaward drift should be a seaward drift at the surface and a shoreward movement at the bottom; if the waves are short, there would be a shoreward movement at the surface and the bottom and a seaward movement in the intermediate depth. For waves 3 ft. high Mr. Barber estimated the velocity of such movements to be of the order of 5 cm. a second.

Little information is available of the water movements between the breakers and the beach. In the model experiments the movements in this part of the tank are difficult to observe because of the strong turbulence; but it was found that dye put into the water between the plunge-line and the beach showed little tendency to pass outwards across the plunge-line. One of the consequences of the termination of the forward movement at the plunge-line is that sand tends to accumulate there; it was also found that the sand does not move uniformly towards the shore but as a series of regularly spaced bars, the spacing being of the same order as the wave-length. In the sea, the formation of bars is complicated by the shifting of the breaker zone relative to the beach as the tide rises and falls, and they are observed particularly off coasts where the tidal range is small. Major Williams mentioned the research into the effect of waves on beaches that is being undertaken in the Department of Geography at Cambridge, and made special reference to widespread occurrence of bars in the Mediterranean Sea. They were a considerable hazard during landing operations, since men, or vehicles proofed for a certain depth, would find water too deep for them if they left a vessel which had grounded on a bar. The movements of such bars are being studied in relation to the waves and other factors.

Major Williams also described how the reduction in the velocity of waves entering shallow water had been used to obtain accurate information about the underwater profile of the beach. By comparing successive aerial photographs of known scale, the wave-length and velocity of waves at different distances from the shore could be measured and the beach profile calculated.

In the discussion which followed, it was remarked that observations and theory tend to discount reports of strong undertow below waves, and suggest that the resultant movement, after allowing for the backward and forward movement of the waves, is towards the shore. The evidence of a seaward movement at the surface appears, on the other hand, to grow stronger. On the coast of California in particular, it has been observed that strong outward movements may develop at certain points on the beach, presumably where the seaward drift is concentrated; the position and intensity of such 'rip-currents', as they are now called, may vary, but they tend to be associated with some irregularity in the beach or where some natural or artificial barrier extends to seaward. Together with the local tidal streams they may account for the danger of bathing in certain localities; they can sometimes be detected because foam or discoloured water is seen moving outwards through the breakers. It is reasonable to suppose that they are stronger with high waves, especially when a group of high waves is followed by a group of low waves, since the high waves will tend to build up a head of water on the beach. Little is known of the behaviour of breaking waves, but it has been assumed with some success that the wave breaks when the water-particle velocity, which depends on the height of the wave, exceeds the wave-velocity, which depends on the depth of water. Such an argument implies a close relationship between the height of a wave and the depth of water in which it will break; and it has been shown that there is a tendency for waves to break when the ratio of water-depth to wave-height is four-thirds.

Prof. J. D. Bernal gave an evening discourse on "Waves and Beaches" on September 13; all available tickets were issued before lunch-time on the first day of the meetings, and the close attention of the crowded hall showed a lively interest in the subject as well as appreciation of the inspiring lecture. After summarizing the studies made during and since the War, Prof. Bernal described their application to military purposes and the prevention of coastal erosion, and showed how a better knowledge of the transport of sand and shingle by waves would be useful in geological studies. In discussing coastal erosion and other coastal engineering problems, he remarked that no other industry spent such a small proportion of its outlay on research, or stood so much in need of accurate knowledge of the basic principles involved and of some central authority.

MULTIPLE ALLELOMORPHS IN COLOUR VISION

By Dr. R. W. PICKFORD
Department of Psychology, University of Glasgow

EVIDENCE has been found that the main forms of defective red-green colour vision in man are multiple allelomorphs, alternative to each other and to the normal form[1]. In order to prove this hypothesis it would be necessary to show: (*a*) that the forms of red-green vision are discontinuous variations; (*b*) that they are inherited true to type; (*c*) that they segregate independently; and (*d*) possibly that they have an order of dominance. It will be seen that the evidence in favour of the hypothesis is very strong.

Discontinuous Variations

The question is very important whether or not the well-known variations of colour vision, two of which are generally called red-green blindness, are the extremes of a continuous normal curve. Rayleigh[1a] threw doubt on the continuous nature of these variations in 1881. He showed that there were red and green anomalous subjects who were characteristically different from the normal, from each other and from the red-green blind as well. This has been confirmed by Pickford[2]. In addition, Rayleigh indicated in the same paper that the two types of red-green blindness were also distinctively different, a conclusion supported by von Kries and Donders[3] and by Pickford more recently[4]; while Houstoun showed by means of his microscope test[5] that the major red-green defectives formed a small and rather irregular group separated clearly from the large group of normal subjects.

In a recent investigation upon some 900 normal and more than 140 red-green defective subjects (the latter not all found by chance), I have found convincing evidence of a statistical kind that there are four or probably five distinct types of red-green vision in addition to the normal form. This research will be published in full as soon as possible (*J. Psychol.*, in the press). The types are: deuteranope, protanope, green anomalous and red anomalous, the latter being divided into two classes, those with and those without the darkened red of the protanope. Whether the two types of red anomalous subjects are statistically distinct is difficult to decide finally on the basis of the eight cases available, but it is extremely likely.

Adequate tests, which will be published shortly, show that the anomalous subjects are not to be viewed as the intermediates between the red-green blind and the normal. To think of the green anomalous as intermediate between the normal and the 'green-blind', while the red anomalous might be intermediate between the normal and the 'red-blind', is highly tempting. There are, however, grave objections to this: (1) neither class of anomalous subjects is sufficiently variable to fill the gap it is supposed to occupy; (2) both the so-called 'red-blind' and 'green-blind' are, in fact, red-green blind; (3) though most red-green blind subjects are more defective, some are actually less defective than the anomalous, who are possibly to be identified with Houstoun's "colour-different" subjects[6]. Edridge-Green was well aware that the anomalous were not true 'intermediates'[7]. It was only in terms of the Young–Helmholtz theory, now rapidly becoming more and more difficult to sustain[8,9], that they could be thought of as true intermediates; indeed, it has long been realized[10], as Rayleigh foretold[11], that the red-green blind cannot be divided into the 'red-blind' and 'green-blind' classes, but must be divided on the principle that while both types are red-green blind, in the protanopes or scoterythrous the red end of the spectrum is greatly darkened, and in the deuteranopes or photerythrous there is no darkening of the red. That about half of the red anomalous do not have th darkened red of the protanope is a fourth objection to treating them as intermediates.

It is inevitable that we should conclude that ther are four (or probably five) types of major red-green vision defects, which are as clearly discontinuou from each other and from the normal as is usual with familiar Mendelian allelomorphs.

Inheritance True to Type

Few people have realized the implications, for th theory of inheritance of colour vision defects, o Rayleigh's pedigree[12] showing the green anomalou condition in three of his brothers-in-law. The seven siblings he tested are shown in Pedigree 1*. Th three brothers who were green anomalous inherite the defect true to type, and were completely differen

Pedigree 1*

---

* Throughout this paper *N* = normal, *d* = deuteranope, *p* = pro tanope, *g* = green anomalous, *r* = red anomalous, *H* = 'norma heterozygote (see section on heterozygotes later in this article), ? = doubtful owing to inadequacy or lack of testing.

from the other brother, who was normal, and from the sisters, who appeared to be unaffected. This pattern of inheritance fits the Mendelian scheme for a recessive sex-linked allelomorph, which would be for the green anomalous condition in this case.

Several published pedigrees show that the same Mendelian principles apply to the red anomalous condition (protanomaly)[13], to the green anomalous condition (deuteranomaly)[14], to deuteranopia[15], and to protanopia[16], although it is only too well known that some tests in common use have not been above scientific criticism, and that the difficulties of collecting information from relatives for the completion of such pedigrees are always very great.

I have confirmed the implications of these pedigrees in every respect, with the exception of not having had the good fortune to trace the red anomalous condition in the relatives of an affected subject because the relatives were inaccessible. Pedigrees 2, 3, 4, 5 and 6 are good examples taken from a large collection*. All pedigrees which have been collected show that the defect is inherited in such a way that it is either manifested true to type (whether in a man or in a woman), or does not appear; and that the mode of inheritance is invariably that of a Mendelian sex-linked recessive[17,18]. Other experiments have shown that it is, in fact, an incomplete recessive, since it generally appears in a small and recognizable degree in normal heterozygotes[19]. Even where the defect appears to pass from father to son[20], the sex-linked pattern is not necessarily contradicted, because it is probable that the mother was a heterozygote, and unless this possibility is excluded we cannot be sure of transmission directly from father to son. The fact that I have found the following three pedigrees (7, 8 and 9) shows that the greatest care is needed concerning this point. Finally, I have found, without exception, that the defects are inherited not only true to type, but also in degree. That is to say, an extreme deuteranope's defective relatives are also extreme deuteranopes, a moderate deuteranope's are moderate, and similarly for protanopes.

Independent Assortment

The independent assortment of types of colour-vision defect is clearly shown by certain published pedigrees, in spite of the possible inadequacy of the tests used. For example, the independent assortment of the red anomalous (protanomalous) condition and an unspecified form of red-green blindness is shown by a pedigree due to Göthlin[21]. That of the deuteranope and an anomalous condition unspecified is shown by pedigrees due to Guttmann[22], that of the deuteranope and the green anomalous (deuteranomalous) condition by pedigrees due to Göthlin and Wölfflin[23]; while that of the green anomalous (deuteranomalous) condition and an unspecified form of red-green blindness is shown by a pedigree due to Döderlein[24]. Finally, the independent assortment of protanopia and deuteranopia is shown by certain pedigrees in which there are some members with one and some with the other defect[25], and one in which father and son had different defects[26], as in my Pedigree 8. It is most unfortunate that many of the collectors of pedigrees of colour blindness have not realized the importance of specifying exactly the type and degree of defect (if any) of each person tested, and, indeed, even more unfortunate that no adequate test has been available in the past for separating the types with complete certainty. In the absence of an adequate method of measuring their heights, we should never have been certain that short peas were on the average shorter than tall peas by an amount differing to a statistically significant degree from zero. Nevertheless, in colour vision, the evidence favouring the hypothesis of the independent assortment of red-green major defects in general and the normal condition is overwhelmingly great, while that favouring the same hypothesis in relation to the different types of defect among themselves is very great indeed.

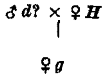
Order of Dominance

The most convincing evidence for the theory that the statistically distinct forms of sex-linked red-green colour vision defect are multiple allelomorphs might come from a study of their combinations. These combinations, however, can occur only in women, and any possible evidence concerning the effects of combinations of defective genes in the same heterozygote will be confined to a proportion of the 0·61 per cent[27] of major defective women. The smallness of this percentage makes research very difficult, and shows that it is of great importance that as many red-green defective women as possible should be discovered and persuaded to undergo adequate tests, together with a sufficient number of their male relatives on both sides of the family, to indicate their genotypes conclusively.

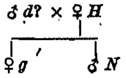
In the present investigation, fifteen red-green defective women were tested efficiently, up to the time of writing, and their pedigrees did in four cases give indications of the possible effect of combinations of different allelomorphic genes, though these were unfortunately all of the same kind. They are Pedigrees 10, 11, 12 and 13. In Pedigrees 10 and 11 the fathers had been dead some time; but there was good hearsay evidence from the relatives that they had been (*a*) colour blind rather than anomalous, because the anomalous rarely become noticed for colour mistakes in the family circle, and (*b*) deuteranopes rather than protanopes, because protanopes usually become notorious by confusions relating to red and

---

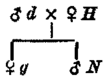
* Where there is a query (?), good evidence, though falling short of a perfectly adequate test, indicated the condition.



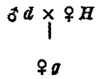
Pedigree 10



Pedigree 11



Pedigree 12



Pedigree 13

black or another dark colour, and in these cases that kind of confusion was not mentioned. In Pedigrees 12 and 13 all relatives were given adequate tests. The four cases all strongly support the view that the daughter was a heterozygote for deuteranopia and the green anomalous condition together, and that the latter was dominant. The possibility that one of the untested fathers was a protanope must be borne in mind, and it would carry with it the implication that the green anomalous condition was still dominant.

In four published pedigrees the underlying principle is the same[28]. All these pedigrees will be found to include a group of relationships such that a green anomalous woman must have been a heterozygote for green anomaly and deuteranopia together, thus again indicating that the green anomalous condition was dominant; and in one of these pedigrees the two conditions segregate independently in the two sons, one of whom is a deuteranope and the other green anomalous.

Four other cases quoted by Bell are also very interesting. One due to Göthlin[29] shows two sons as protanopes, while the father and maternal uncle are both deuteranopes. Here it would not be an unlikely hypothesis that the mother was a protanope heterozygote, inheriting that condition from her father, for her two sons, who must follow the mother, are both protanopes. Another case, also due to Göthlin[30], shows two sons as deuteranopes, two as protanopes and the daughter as normal, while both parents were said to have been normal. A case due to Jeffries[31] shows one son a protanope and the other a deuteranope, while no information is given about the parents. In these two pedigrees the mother might possibly have been a heterozygote for protanopia and deuteranopia together, and, since she was believed to be normal in the one case while no information was given about her in the other, the possibility arises that this particular heterozygote does not differ much from the normal condition, though it is more likely that the defect was not revealed by the tests used. A fourth case, due to Hess[32], shows father and daughter as deuteranopes, though it is not known for what condition the mother was a heterozygote. It is clear that added information in this case would have been most valuable, as in so many others.

Heterozygotes

If it is true that there are five defective allelomorphs for red-green colour vision, then the possible number of genotypes in women will be twenty-one. Of these, one will be the normal homozygote, five defective homozygotes, five normal heterozygotes and ten will be defective heterozygotes. The probable frequencies of these genotypes may be calculated from the observed frequencies of the corresponding defects in men[27], and some would be very rare indeed. It has been shown that the majority of the normal heterozygotes have a small red-green defect[19]. Fuller study of these and of the other combinations would be most valuable.

Conclusion

The hypothesis that there are six multiple allel morphs for red-green colour vision and its defects i man is supported by the following evidence: (*a*) A least four and probably five different types of re green sex-linked defect are statistically distinc namely, deuteranopia, protanopia, green anomal red anomaly with and red anomaly without th darkened red of the protanope. (*b*) Many pedigre indicate that these are inherited true to type, or n at all. (*c*) Many pedigrees show that these typ segregate independently. (*d*) Eight pedigrees sho that the green anomalous condition is dominant t that of the deuteranope, while all the defective form are recessive to normal red-green colour vision.

OBITUARIES

Prof. Alan F. C. Pollard

FEW people in the world of science and engineerin have had such a strong sense of order and directio as Alan Faraday Campbell Pollard, who died suddenl at the age of seventy years at Thames Ditton o August 15. He was essentially a crusader, and hi sense of mission was such that he spared no amoun of trouble and effort to further the objects in whic he so optimistically believed. He will perhaps b best remembered both for his efforts to reform method of instrument design on a sound scientific basis, an not less for his untiring advocacy of comprehensiv schemes for indexing scientific literature and, in fact all serious knowledge. He was fortunate that in thes things he seemed, comparatively late in life, to fin his true *métier*, when the very varied experiences o his earlier days had given him a foundation on whic to build.

The son of Lieut.-Colonel B. H. Pollard, of the Indian Staff Corps, he thought at first of an Army career, but later studied medicine at St. Bartholomew's Hospital and King's College, London. Circumstances making it impossible for him to complete his medical training, he turned to engineering, which he studied at University College and (as an apprentice) at Siemens Bros. However, during his period at University College, he acted for some time as demonstrator and assistant to Prof. Karl Pearson, a contact which powerfully affected his thought and methods.

In 1911 Pollard joined the staff of Nobels Explosives, Ltd., and established a special physical laboratory at Croydon for this firm. He was presently given the post of chief physicist and superintendent of the firm's testing station, but on the outbreak of war in 1914 he was gazetted a second lieutenant in the Royal Scots Fusiliers (having previously held a commission in the militia forces). In 1918 he was appointed sub-director of the Instrument Section in the Ministry of Munitions (Aircraft Production) and was gazetted captain in the R.A.F. However, the exigencies of war had led to the formation of a Technical Optics Department at the Imperial College, under the directorship of the late Prof. F. J. Cheshire, and Pollard was appointed to the chair of instrument design, which he held until he reached the age of sixty-five. Even then he seemed to have lost little of his health and vigour, and until his death he was director and consultant to Messrs. Daniel Varney, Ltd. He was awarded the degree of D.Sc. (Engineering) in 1943. He was made a professor emeritus of the Imperial College and held numerous honorary posts of public importance.

Being extremely inventive and versatile, Pollard developed many instruments and appliances, including a new nephelometer, appliances for artificial limbs, reflector lights, an interchangeable nosepiece for microscope objectives, and many other things. He felt very strongly that instrument makers in Great Britain were dominated by ideals more appropriate to heavy engineering production than to scientific instruments, and he turned to the kinematical theories of Clerk Maxwell as a satisfactory basis for reform. His views were expounded especially in his Cantor Lectures to the Royal Society of Arts in 1922, and in a book on "The Kinematical Design of Couplings in Instrument Mechanisms", published in 1929 by Adam Hilger, Ltd. He tried to show that instrument design is essentially a special subject and demands a discipline all its own. Although his chair at the Imperial College has not so far been filled, it may be claimed that his influence can be felt in such steps as the beginning of the new Department of Instrument Technology at the Northampton Polytechnic, London, and in numerous examples of modern instruments in which kinematical principles are employed.

Pollard had essentially a tidy mind, and he loved card-indexes and files. His personal possessions were well catalogued ; he did not keep his gospel merely for others. This trait was sometimes the source of quips by others with more haphazard methods—'slovenly' was his most severe word of scorn, and there was unholy joy when on one occasion he was human enough to lose a library book. The Universal Decimal Classification made an instant appeal to him, and he not only became an enthusiastic advocate, but also contributed very materially to its development in the field of optics. He became the first president of the British Society for International Bibliography in 1927, and took a leading part in the conferences of the International Federation for Documentation held on the Continent. A noteworthy address was on "A Proposed Plan for the Mobilization of the Bibliographical References to the contents of the World's Non-fiction Literature", in which there is a plan for National Bureaux of Information which might, working under an International Information Council, make (and keep up to date) complete U.D.C. indexes of human knowledge; for a student of a special subject might then obtain all the useful references to papers or books in his field simply by citing the appropriate classification numbers. He beheld with dismay human knowledge growing not only out of control but also out of reach. Like H. G. Wells, he believed in wisdom as contained in books, and wanted badly to make it accessible. He will be missed in an age in which such optimism is more rare, but at least he has helped us to grasp the magnitude of the problems involved.

Pollard had a wide circle of friends both in Great Britain and abroad, and was always willing to give time and attention to those who asked his help or advice. In 1915 he married Gabrielle, daughter of Mr. Frederick Urwick, and he leaves also a son and a daughter.

L. C. MARTIN

Mr. G. J. Arrow

WE regret to record the death on October 5, after a brief illness, of Gilbert John Arrow, late deputy keeper in the Department of Entomology in the British Museum (Natural History). Born on December 20, 1873, the son of John Garner Arrow, of Streatham, Arrow was trained for the profession of architecture, but in 1896 entered the more congenial service of the British Museum (Natural History) at South Kensington. Here he was assigned to the study of beetles and early specialized on the Lamellicornia, upon which group he soon made himself an authority. His greatest work was the four volumes on the Lamellicorn Coleoptera of the Fauna of India series. He also contributed numerous papers, more than a hundred in all, to the *Transactions of the Royal Entomological Society of London*, the *Annals and Magazine of Natural History*, and other scientific journals.

Mr. Arrow retired under the age limit in 1938, but continued voluntarily his work at the Museum until within a few weeks of his death. This work was of untold value to the Museum, especially during the war years and the trying times that followed, and was recognized by the Trustees of the Museum by the bestowal upon him recently of the special distinction of 'honorary associate' of the British Museum. His imperturbability was immense ; he would continue calmly at work during air-raid warnings, and even when found under a shower of glass when a flying bomb fell almost outside his window, his main concern was that he could not find his spectacles.

He was a great lover of music, and did much to encourage musical talent among the junior members of the Museum staff until increasing deafness made this no longer possible. He was also an expert photographer and would frequently use his own photographs in illustration of his papers.

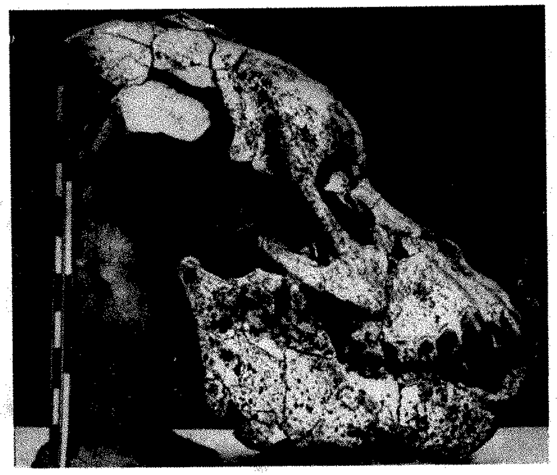
He married in 1912 Miss Rachel Katharine Davis, who survives him, and to whom we would tender our sincere sympathy in her bereavement.

K. G. BLAIR

NEWS and VIEWS

Skull of *Proconsul* from Rusinga Island

THE second season's work of the British–Kenya Miocene Expedition in the Kavirondo region of Lake Victoria has culminated in one of the most important discoveries yet made there. Dr. L. S. B. Leakey, the field director of the Expedition, has announced the finding on Rusinga Island on October 2 of the greater part of a skull of one of the species of Miocene apes belonging to the genus *Proconsul*, probably *Pr. africanus* (Hopwood). Up to now, fossil remains of Miocene and Pliocene apes in Africa and other parts of the world have been practically confined to teeth and fragments of jaws, and this new discovery for the first time provides information regarding the whole of the facial skeleton and much of the brain case. As will be seen from the accompanying photograph, the jaws and facial skeleton are remarkably complete, though they are somewhat displaced by distortion on the left side. The forehead region is particularly interesting, for it shows a complete absence of the supra-orbital torus which is so characteristic of the modern African anthropoid apes. Another interesting feature is the unusual thinness of the cranial wall. The specimen is extremely fragile, and evidently must have required consummate skill for its successful removal from the deposits in which it was found. Mrs. Leakey was actually the first to see some small fragments of the skull, where they had been washed out on the slope of one of the gullies which were being explored. She directed the attention of her husband who, cutting back into the beds, brought to light this most important, and indeed unique, fossil. Mrs. Leakey is bringing the skull by air to Great Britain, where she expects to arrive on October 31, and in the first instance it will be deposited at the Department of Human Anatomy at Oxford, where it will be studied in detail, in connexion with more than a hundred other specimens of Miocene fossil apes which the British–Kenya Miocene Expedition has collected over the last two years. It is particularly gratifying to note that this Expedition, which was mainly financed in its first year (1947) with the aid of a grant from the Royal Society, has proved such an outstanding success. Apart from the fine collection of fossil Primate material, many hundred specimens of other Early Miocene vertebrates have also been accumulated.



Skull of *Proconsul*. On the left are centimetre and inch scales. ½ naturalsize

Millport Marine Laboratory: Mr. R. Elmhirst

MR. R. ELMHIRST retires from the directorship of the Millport Laboratory on March 31, 1949. His association with the Laboratory goes back to 1906, when he was appointed to the staff as naturalist, after previous experience at Plymouth and Monaco. On the resignation of the director, Mr. S. Pace, in the following year, he was appointed superintendent and has been in charge of the Laboratory, apart from service with H.M. Navy during the First World War, since that date. He was appointed director in 1933. For many years Mr. Elmhirst *was* the Millport Laboratory, the sole member of the scientific staff, and he maintained it in being during the difficult years that preceded 1914. After 1921, when financial aid came from the Development Commission, the staff was enlarged and the Laboratory under his guidance made steady progress to its present high standing as a research institute. Mr. Elmhirst is an accomplished field naturalist who has guided and stimulated the interests of generations of students and research workers. The Easter classes he has conducted at Millport have played a big part in the education of British marine biologists, and he has lectured on marine ecology in the Department o Zoology at Cambridge. As a popular lecturer he has long been well known to Scottish audiences. His knowledge of the fauna and flora of the Clyde Sea area is unique and will be greatly missed when he leaves Millport. His observations and experiments are recorded in a long series of papers and also i his revision of Newbiggin's "Life by the Seashore" A bibliography of his writings and a more detaile account of his career will appear in the annual repor for 1948–49 of the Scottish Marine Biological Association. Their many friends will join the member of the Association in wishing Mr. and Mrs. Elmhirs much happiness in retirement.

Mr. E. For

MR. E. FORD, assistant director of the Marin Laboratory, Plymouth, will succeed Mr. Elmhirst After graduating at the Royal College of Science Mr. Ford gained the Sarah Marshall Exhibition fo research work as Huxley Scholar in 1913 and wa appointed assistant naturalist at Plymouth at th end of that year. He served as an infantry officer i the First World War, when he was wounded i Belgium, and again on the staff of the R.A.F. a intelligence officer during 1941–45. His work a Plymouth, where steady promotion culminated i his appointment as assistant director in 1935, ha been primarily on fish, and he is the author of series of admirable studies on larval and post-larva fishes, on the life-history of the dogfish, on herrin and on osteological variation in the backbone an the skull. In addition, he extended the quantitativ survey of bottom fauna, initiated by Petersen, to th waters of Plymouth Sound. He was 'Bucklan Professor' in 1936, and his lectures have been pub lished under the title of "The Nation's Sea-Fis Supply". The Scottish Marine Biological Associatio may be considered most fortunate in persuading M Ford to assume responsibility for the further develo ment of the Millport Laboratory, where his admini trative ability, his high scientific attainments an above all, his qualities of friendly leadership will fin full scope.

Mr. Ford will take over scientific staff and equipment greatly exceeding what existed before the War. Apart from Dr. A. P. Orr, recently appointed deputy director, and Dr. Sheina M. Marshall, who did so much to establish the reputation of the Laboratory before the War, the staff now consists of three zoologists, a chemist and an algologist, while a further post has been authorized but is not yet filled. A new research vessel, the *Calanus*, has recently been acquired and is now operating from the Laboratory. She is a motor fishing vessel, 75 ft. long, of which the hull only was built when she was purchased from the Admiralty, so that it has been possible to fit her out as a research vessel with all the modern equipment needed for both physical and biological investigations in the sea. She carries a permanent crew of five, and will enable the Millport Laboratory to extend the range of its work from the Clyde sea area to the west of Scotland generally. A much belated addition to the facilities of the Laboratory is the provision recently of electric current from the hydro-electric grid system. It will now be possible to use standard electrical equipment; further, a workshop with power-driven tools is being constructed. The Millport Laboratory, which has always had the advantage of being adjacent to clean waters with a rich fauna and flora, has now both the research vessel and the laboratory facilities for making full use of its natural advantages.

Prof. P. C. Mahalanobis, F.R.S.

PROF. P. C. MAHALANOBIS retired from the Indian Educational Service and from his post as principal of Presidency College, Calcutta, on June 30. He is chiefly known as a mathematical statistician with wide interests, and particularly as a pioneer in the theory and practice of sample survey. His work in building up the Statistical Laboratory at Presidency College is appreciated throughout the world, and it is undoubtedly one of the best centres for statistical research and advanced teaching. In recent years, Prof. Mahalanobis has been largely engaged on the Statistical Commission of the United Nations. He is still carrying on his scientific work, especially in the Indian Statistical Institute, of which he is honorary secretary.

Plant Physiology at Ghent: Prof. Paul Froeschel

DR. PAUL FROESCHEL has been appointed professor of plant physiology at Ghent State University as a successor to the late Prof. G. L. Funke. Dr. Froeschel was born in Vienna in 1888. He studied botany and especially plant physiology with Julius v. Wiesner, Richard v. Wettstein and Hans Molisch, and became known for his work on plant irritability and especially short phototropic presentation times. After graduating, Dr. Froeschel worked with Prof. Linsbauer (Czrnowitz), Prof. Goebel (Munich) and Prof. Wasitzky (Vienna). At the end of the First World War he took up agriculture; he worked on the cultivation of medicinal plants, and as an agricultural consultant he had the opportunity of becoming closely acquainted with agricultural problems. In 1938, Dr. Froeschel emigrated to Belgium, where he was given a place in the department of Prof. Funke, director of the plant physiology laboratories of Ghent State University. There Dr. Froeschel in the first place worked on the growth-inhibiting substances of plants, and furnished valuable contributions not only to the physiology of these substances, but also to their practical use.

Cocoa Disease in the Gold Coast

THE Secretary of State for the Colonies has appointed the following commission to visit the Gold Coast and report on the measures necessary for the eradication of swollen shoot disease of cocoa trees: Dr. G. Berkeley, of the Dominion Laboratory of Plant Pathology, Canada; Dr. W. Carter, head of the Department of Entomology, Pineapple Research Institute, Hawaii; and Prof. van Slogteren, of Holland. Their terms of reference are: "Having regard to the research work in swollen shoot disease of cocoa trees in the Gold Coast being carried out by the West African Cocoa Research Institute, to study the incidence and nature of the disease and to report on the technical measures necessary for its speedy eradication".

British Museum (Natural History): Acquisitions

THE following acquisitions to the British Museum (Natural History) have been announced: Sir Sidney Harmer, director of the Museum from 1919 to 1927, has presented 374 volumes of reprints and zoological publications dealing principally with Cetacea and Polyzoa, together with card-indexes of authors and subjects. The Governing Body of King's College, Newcastle-upon-Tyne, have given about 10,000 slides of Crustacea and Foraminifera containing the type specimens of many species collected by the *Challenger* and other expeditions for the exploration of the sea; these slides were prepared by the late Prof. G. S. Brady. The extensive collection of Diptera formed by the late Colbran J. Wainwright, a recognized authority on the study of this order of insects, has been presented by his daughters, Miss Wainwright and Mrs. Reid; the collection is estimated to contain approximately 65,000 specimens, of which the greater part are from the palæarctic region, although some 18,000 are from other parts of the world. Finally, three important bequests have been made to the Department of Botany, the first being the remainder of the late Colonel A. H. Wolley-Dod's herbarium and consisting of about 10,000 sheets of British plants mainly of his own collecting (Colonel Wolley-Dod was the author of "Flora of Sussex", and his herbarium contains many of the specimens on which records were based). Second is the very important collection of British and European plants estimated at 30,000 specimens and brought together by the late Mr. Herbert William Pugsley; the material is excellently preserved and the alpine plants are exceptionally good. The third bequest is that of the late Mr. J. W. Long's herbarium of about 15,000 sheets of British and European plants.

Marconi Jubilee Congress

THE publication is announced of the *Proceedings* of the International Congress held in Rome last September in connexion with the Marconi Jubilee (see *Nature*, November 29, 1947, p. 473). The volume, which comprises some 970 pages and 470 illustrations, is published by Dr. Giovanni Bardi, Salita de' Crescenzi 16, Rome, at the price of 4,000 lire. In a preface, Prof. Gustavo Colonnetti, president of the Italian National Research Council, describes the aims of the Congress, and the success which accompanied it with the interested support of many participants from various nations. The full texts of the fifty-nine papers, of which ten are by British authors, are reproduced in the volume, classified in four sections under the titles of electromagnetic waves, electric and acoustic oscillations, electronics and radiocommunication. The papers are published in the language in which they were submitted by the authors. The numbers of papers in the four sections, with those in English indicated in brackets, are: 14 (9), 21 (8), 8 (5) and 16 (10). The publication provides an interesting survey of the many scientific and technical developments in this field in the half-century following Marconi's first successful demonstration of wireless signalling.

New Zealand Earthquakes during June

DURING June, five strong earthquakes were registered on the New Zealand seismographs at Arapuni, Auckland, Christchurch, Kaimati, New Plymouth, Tuai and Wellington. The one on June 28 was that which destroyed the Japanese city of Fukui, and that on June 29 was felt at Apia with Modified Mercalli Scale 5. In addition, twenty-three earthquakes and earth tremors occurred within 10° of Wellington. The greatest two of these both occurred on June 19 and were felt extensively in South Island but particularly near Bruce Bay with Modified Mercalli Scale 6.

The Night Sky in November

NEW moon occurs on Nov. 1d. 06h. 02m., U.T., and full moon on Nov. 16d. 18h. 31m. The following conjunctions with the moon take place: Nov. 3d. 17h., Mars 2° N.; Nov. 4d. 20h., Jupiter 4° N.; Nov. 24d. 02h., Saturn 3° S.; Nov. 28d. 06h., Venus 2° N. Mercury rises at 5h. 10m. and 5h. 49m. on Nov. 1 and 15, respectively, and can be seen in the eastern sky. The planet reaches its greatest easterly elongation on Nov. 4. At the end of the month Mercury rises only half an hour before sunrise and is then too close to the sun for observation. Venus rises at 3h. 15m., 3h. 55m. and 4h. 40m. at the beginning, middle and end of the month, respectively, and can be seen in the morning hours, stellar magnitude −3·5; 0·75 to 0·84 of the illuminated disk is visible. Mars is too close to the sun to be favourably observed, setting about 1¼ hours after the sun throughout the month. Jupiter sets at 18h. 55m., 18h. 10m. and 17h. 25m. at the beginning, middle and end of the month, respectively, and can be seen low in the western sky; but it is not favourably placed for observation through the greater portion of the month. Saturn, in the constellation of Leo, rises at 0h. 45m., 0h., and 23h. at the beginning, middle and end of the month, respectively, and is visible throughout the morning hours, stellar magnitude 0·9. Occultations of stars brighter than magnitude 6 are as follow: Nov. 8d. 17h. 51·1m., 35 Capr. (*D*); Nov. 19d. 01h. 13·1m., 112B Auri. *m*, (*R*); *D* and *R* refer to disappearance and reappearance, respectively, and the latitude of Greenwich is assumed. A total eclipse of the sun takes place on Nov. 1. The eclipse is invisible at Greenwich, but is visible over large portions of the southern hemisphere. The central line passes through lat. + 3° 42′, long. − 22° 03′, at the beginning of the eclipse and ends at lat. − 43° 23′, long. −165° 27′.

Announcements

THE Lord President of the Council has made the following appointments to the Advisory Council for Scientific Research: Mr. James Bowman, vice-president of the National Union of Mineworkers, and a member of the T.U.C. Scientific Advisory Committee; Mr. E. Fletcher, secretary of the Research and Economic Department of the T.U.C.; and Dr. H. W. H. Warren, managing director of Associated Electrical Industries, Ltd.

THE Cambridge Philosophical Society announces that the adjudicators for the Hopkins Prize have made the following awards: for the period 1939–42, to Prof. H. J. Bhabha, for investigations on the theory of elementary particles; for the period 1942–45, to Dr. C. F. Powell, for experimental investigations in nuclear physics, including development of the photographic plate technique for the study of nuclear reactions.

AN Eddington Prize of 50,000 Belgian francs is being offered by the Institut International des Sciences Theoriques for an exposition and critique of the conceptions of Eddington concerning "The Philosophy of Physical Science". The committee of award consists of Dr. I. Dockx, director of the Institute; Prof. L. de Broglie (Paris); Prof. Th. de Donder (Brussels); Prof. F. Gonseth (Zurich); and Prof. E. A. Milne (Oxford). Memoirs (five copies) must be submitted to the secretariat of the Institut International des Sciences Theoriques, 221 avenue de Tervueren, Brussels, before December 31, 1950. Participants must sign their memoirs by a device, and include a sealed envelope containing name and address.

THE Atomic Scientists' Association is holding its annual conference at the Beaver Hall, Garlick Hill, London, E.C.4, on October 30. There will be two sessions, the first from 2.30 to 5 p.m., and the second from 7 p.m. to 9.30 p.m. The first session is concerned with "Atomic Energy and Society", and speakers will include Prof. P. M. S. Blackett on atomic weapons, Sir George Thomson on international control, Prof. N. F. Mott on national policy, and Prof. M. H. L. Pryce on the constructive applications of atomic energy. In the evening, speakers will include Sir Henry Dale, Prof. R. E. Peierls and Prof. M. L. Oliphant on the position of scientific men with regard to atomic energy and related problems. The hon. general secretary, Dr. F. C. Champion, will conclude with an outline of the future policy of the Association.

A SERIES of lectures for schools, which began on October 20, has been organised by the Institution of Civil Engineers, the Institution of Electrical Engineers and the Institution of Municipal Engineers, in co-operation with the Education Officer of the London County Council. The lectures are being given at the Institution of Civil Engineers, Great George Street, Westminster, S.W.1, and deal with such subjects as railway transport, water and electricity supply, tunnelling, telecommunications, etc. These lectures, which can be given either at individual schools or for groups of schools, are supplemented by the annual Christmas lectures to boys at the Institution of Civil Engineers. For Christmas 1948 the subject will be "Big Ships and their Docks"; three lectures will be given: "Building Big Ships"; "Running and Navigating a Ship"; and "Constructing a Dock".

ERRATUM.—In "Dielectric Properties of Mixed Barium and Strontium Titanates at 10,000 Mc./s." printed in *Nature* of October 23, p. 655, Fig. 2 should be rotated 90° clockwise; the descriptions of the axes remain as they are.

New Method for the Separation, Detection and Estimation of Inorganic Compounds

A FEW years ago, Dr. A. J. P. Martin and his olleagues at the Wool Industries Research Associaion[1] developed a technique using solvent extraction n absorbent paper for the separation and detection f mixtures of amino-acids. This process, which the iscoverers termed 'partition chromatography', has nore recently been applied to other problems, for xample, the separation and identification of amino-cids derived from human metabolism[2], and to the nalytical study of different varieties of penicillin in nixtures[3].

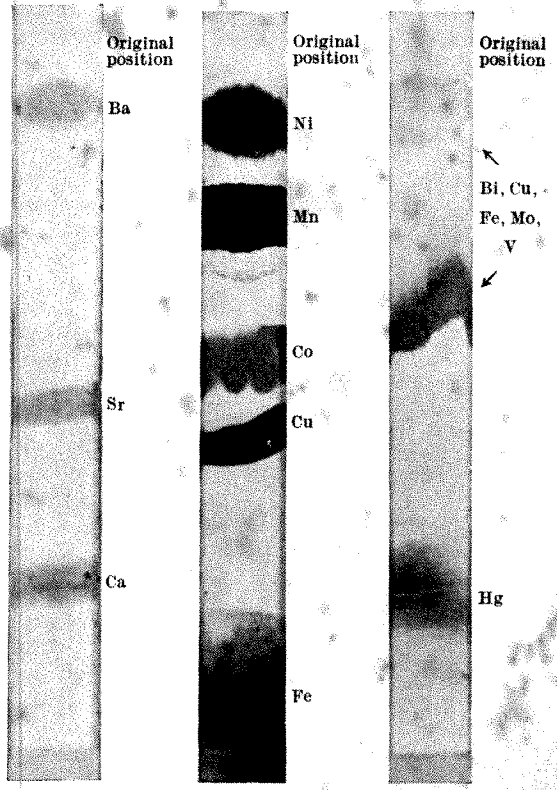
We have now applied a similar procedure to nvestigations in the inorganic field with marked uccess. The essential feature is the combined use f an *organic solvent* (generally containing some acid r other reagent) and an adsorbing material, such as ellulose, for the separation of inorganic substances. he present note gives examples of the progress hich has, so far, been achieved from qualitative nd quantitative investigations of metallic salts. The tudy of other materials is in progress.

The main technique which we have employed, and hich is described below, is essentially the paper-trip method of Martin, Gordon and their collabortors. We have also obtained very promising results n a larger scale which will be described shortly.

Method. A measured volume of the solution to be tudied is placed near one end of a strip of absorbent aper, such as Whatman No. 1 or No. 3 filter paper, o form a small patch about 1 in. square which is llowed to dry in air. The paper strip is then transerred to a gas jar or similar vessel fitted near the op with a container for organic solvent and adjusted o that the end nearest the test patch is immersed n the solvent tank while the remainder of the paper angs vertically down the jar. A vessel containing n aqueous solution is usually placed at the bottom f the jar to maintain suitable conditions of humidity. he organic liquid is allowed to diffuse down the paper ufficiently far beyond the test patch to achieve he desired separations, after which the paper strip s removed, dried in a draught of warm air and tested ith suitable reagents for development of characterisic colours. For qualitative or semi-quantitative work he stains produced are compared with standard olours formed from known amounts of material, hereas in more accurate quantitative estimations the oloured band is cut out, organic matter destroyed, nd the metallic content determined by the polaroraph, colorimeter, spectrograph or by other suitable icro-methods.

Results. Examples of the separation of metals are iven below.

(1) *Calcium, strontium and barium* (see illustraion). These elements can be separated as the chlorles with pyridine containing 4 per cent of potassium hiocyanate as solvent. Under these conditions the alcium travels the greatest distance down the paper, arium moves very little and strontium appears beween the two. Sodium rhodizonate is employed for he development of barium and strontium, and lizarin for the calcium.



(2) *Aluminium, gallium, indium and zinc.* This group has been studied as solutions of the chloride, and with n-butyl alcohol containing hydrochloric acid as the solvent. Aluminium scarcely moves at all, gallium travels down with the solvent front, while indium appears between the two. As zinc is a common impurity in indium and gallium, it has also been included in this series. It appears between the indium and gallium. Aluminium and gallium are developed with 'aluminon', while dithizone is used for indium and zinc.

(3) *Vanadium.* This element can be separated from a large number of other metals by using diethyl ether or tetrahydrosylvane (2-methyl tetrahydrofurane) containing nitric acid and a small quantity of hydrogen peroxide as the solvent. The vanadium moves as a pink band due to the formation of a soluble peroxy-compound. Colour development is achieved with 8-hydroxyquinoline.

(4) *Mercury* (see illustration). Tetrahydrosylvane, or tetrahydropyran, may also be used to separate mercuric chloride from many other metallic chlorides. These solvents, containing hydrochloric acid, quickly carry mercury down the paper, leaving the other salts behind. The position of the mercury is revealed by means of dithizone, and it can be estimated quantitatively by standard methods after such separation.

(5) *Cobalt, copper, iron, manganese and nickel.* The chlorides of these metals can be readily separated using methyl n-propylketone or acetone containing hydrochloric acid. Mixtures of these solvents may be employed, a convenient one being 80 per cent methyl n-propylketone, 10 per cent acetone and 10 per cent concentrated hydrochloric acid. Iron moves the greatest distance, followed by copper, cobalt and manganese; nickel moves only slightly.

For the best results it is advisable in this case, as also in the separation of aluminium, gallium and indium, to maintain the relative humidity in the chamber at 65 per cent. Nickel, cobalt and copper are identified by means of rubeanic acid; manganese by reduction of ammoniacal silver solution; and iron by potassium ferrocyanide. Nickel and cobalt have been determined quantitatively by polarographic measurements. Some typical results are illustrated in the accompanying reproductions.

Limits of detection and estimation. The procedure provides a delicate means of separating and estimating small quantities of metallic ions. The limits of detection vary with different elements and depend on the sharpness of the bands and the sensitivity of the spot tests. Quantities of the order of 1·0–0·1 microgram have been detected, while the normal range for quantitative work is in the region of 5–200 micrograms.

Mechanism. The processes involved in this type of separation are being investigated; but it is clear that a number of factors must be taken into consideration. These are: (*a*) selective extraction of the salts by the organic solvent, an effect prevailing at the site of the test patch; (*b*) where substantially immiscible solvents are used, partition of the inorganic substances between organic solvent and aqueous layer, since water is present as a normal constituent in the absorbent paper and is usually added to the organic solvent; this partition, therefore, takes place as the liquid mixture moves down the paper, and separations are due to slight changes in conditions at different points on the absorbent strip; (*c*) adsorption of metallic ions by the paper; (*d*) the formation of complexes with high solubility in organic media under specific conditions.

In view of the uncertainty as to mechanism, it seems to us best for the present to refer to this method non-committally as 'extraction analysis'. Further study will, it is hoped, provide a logical theoretical background for the processes taking place.

The investigations so far carried out indicate that the broad application of this and closely related techniques should make possible the separation, detection and estimation of a very wide range of inorganic products. The method is simple and fairly rapid, requires only very small quantities of material, operates with complicated mixtures of ions and does not demand any specialized equipment, at least for qualitative examination. The work is being actively pursued at this Laboratory.

We wish to acknowledge the collaboration in the experimental work of the following colleagues: Miss J. M. Clarke, Mr. N. F. Kember, Miss A. P. McGlone, Mr. I. C. Macwilliam, Miss P. J. Maple, Miss J. M. Patterson and Mr. R. A. Wells. More detailed publications will follow in due course.

Synthesis of Colchicine Derivatives

While the methoxylated carbon-system of (IV) is conclusively established for certain degradation products of colchicine[1,2], the synthesis of such unsymmetrically substituted dibenz*cyclo*heptatrienes, necessary for further work, has hitherto miscarried because of difficulties which are partly concealed and partly apparent[2–4]. A synthesis which promises to afford the requisite degree of adaptability has now been found and is based on the oxidation of appropriate 9- or 10-methylphenanthrenes with osmium tetroxide in benzene-pyridine[5,6]. In a model experiment, 9-methylphenanthrene (I) was thereby oxidized to 9 : 10-dihydroxy-9 : 10-dihydro-9-methylphenanthrene (II), m.p. 130–131° (found: C, 79·9; H, 6·1; $C_{15}H_{14}O_2$ requires C, 79·7; H, 6·2 per cent), from which, by cleavage with lead tetra-acetate and renewed cyclization, there was obtained the known 3 : 4 : 5 : 6-dibenz*cyclo*hepta-1 : 3 : 5-trien-7-one (III)[3] Similarly, 2 : 3 : 4 : 7-tetramethoxy-10-methylphenanthrene, m.p. 134–135° (found: C, 73·2; H, 6·4 $C_{19}H_{20}O_4$ requires C, 73·1; H, 6·4 per cent), was converted *via* the corresponding 9 : 10-dihydro-9 : 10 diol, m.p. 156° (found: C, 66·0; H, 6·4; $C_{19}H_{22}O$ requires C, 65·9; H, 6·4 per cent) into the unsaturated ketone (IV), which was identical with the part product previously obtained[1] by oxidizing deamino-colchinol methyl ether with sodium dichromate in acetic acid.

Structure of Ketoyobyrine

THE recent publication of a paper by Woodward and Witkop[1] suggesting a new structure for ketoyobyrine, based on degradative evidence, and of another by Schlittler and Speitel[2], claiming the synthesis of this substance, prompts us to point out that on May 28, 1948, we submitted to the Chemical Society a paper describing the synthesis of ketoyobyrine. This has been accepted for publication in the *Journal*; but unfortunately its appearance cannot be expected for many months.

In the main, our work is along similar lines to that of Schlittler and Speitel; but differs in certain details.

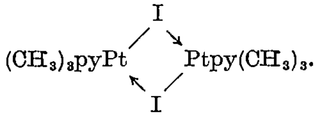
Trimethylplatinum Derivatives

Lile and Menzies[1] report some new derivatives in the trimethylplatinum series, the first members of which were prepared from platinum tetrachloride some forty years ago by Pope and Peachey[2]. Since we are similarly engaged in investigating these compounds, it is desirable to record some of our observations on this subject.

(*a*) *Cis*-dipyridinetetrachloroplatinum, $Ptpy_2Cl_4$, which unlike platinum tetrachloride is not hygroscopic, is a very good source of trimethylplatinum derivatives, just as pyridinetrichlorogold, $AupyCl_3$, is the most convenient starting material for the preparation of dialkylgold compounds[3].

(*b*) Methylmagnesium iodide and *cis*-$Ptpy_2Cl_4$ gives in excellent yield the compound $(CH_3)_3PtpyI$, which decomposes slowly at temperatures above 150°. It is soluble in pyridine, chloroform and in benzene, in which it is dimeric by the freezing-point; thus the 6-covalency of the platinum is maintained as in



$$(CH_3)_3pyPt\begin{matrix}I\\ \nearrow\ \searrow\\ \nwarrow\ \swarrow\\ I\end{matrix}Ptpy(CH_3)_3.$$

(*c*) By treatment with further pyridine, this new compound is converted into $(CH_3)_3Pt(py)_2I$, m.p. 168°, without decomposition. The complex formed from $(CH_3)_3PtI$ and pyridine, described by Lile and Menzies, has the same composition and melting point and is presumably identical with ours. It is of interest that the same isomer is formed by the two alternative routes. In the tetrameric $(CH_3)_3PtCl$ (in which the platinum has an octahedral configuration[4]), the three methyl groups are all *cis* to one another, and it may well be that this same arrangement persists throughout.

We have also observed that the dipyridine complex undergoes dissociation in benzene solution, probably into pyridine and the dimeric complex mentioned in (*b*) above.

(*d*) The other molecule of pyridine is certainly much more firmly held and cannot be removed by dilute acids and alkalis. It is displaced with ease, however, when ethylene diamine is added to a cold chloroform solution of the dimer, and the compound $2(CH_3)_3PtI.3en$ (see also Lile and Menzies, *loc. cit.*) separates in crystalline condition.

(*e*) Although methylmagnesium iodide reacts so readily, no product has been obtained from ethyl magnesium iodide and *cis*-$Ptpy_2Cl_4$. This recalls Pope and Peachey's inability to prepare ethyl derivatives from platinum tetrachloride[5].

(*f*) *Trans*-$Ptpy_2Cl_4$ has so far given no alkyl derivative with methyl magnesium iodide. It undergoes reduction and halogen exchange with formation of trans-$Ptpy_2I_2$.

Work in this field is proceeding, and a fuller account will be given elsewhere in due course.

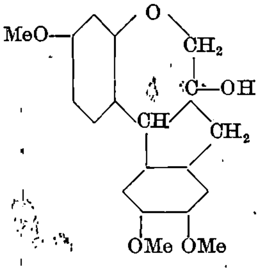
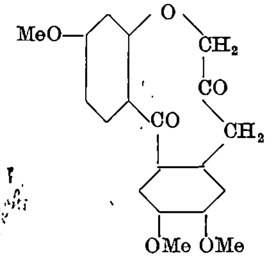
Structure of O-Trimethylbrazilone

OXIDATION of O-trimethylbrazilin (I)[1] yields O-trimethylbrazilone (II), the proposed structure[2] of which is satisfactory in most respects. Nevertheless, the explanation of the unusual loss of two atoms of oxygen which occurs when it is converted into deoxytrimethylbrazilone (anhydrotrimethylbrazilin) by interaction with phenylhydrazine is not apparent.



I

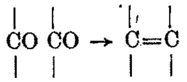


II

It was therefore thought desirable to examine the infra-red absorption spectra of (I) and (II). The spectra were measured in a double-beam spectrometer, using a very dilute solution in carbon tetrachloride at 3 μ and a solid suspension in 'Nujol' at 6 μ. As was to be expected, (I) exhibited an absorption band at a frequency of 3,610 cm.$^{-1}$ and no marked absorption in the 1,720 cm.$^{-1}$ region, indicative of the presence of the hydroxyl group and the absence of any ketonic grouping respectively; (II), on the other hand, showed no absorption in the region of 3,610 cm.$^{-1}$, but exhibited a strong band at 1,720 cm.$^{-1}$. This is consistent with the absence of a hydroxyl and the presence of a ketone group. Moreover, it follows that if there is a ketone group present any modified structure such as $\underset{O-O}{>C-C<}$ is untenable, and it therefore appears that the proposed large ring, diketone structure is correct.

Herzig and Pollak[3] prepared a monoxime of O-trimethylbrazilone, m.p. 203–205° (decomp.). Repetition of this preparation has now yielded two forms of the monoxime; one (from aqueous alcohol) consisted of fine needles, m.p. 197° (decomp.) (found: C, 63·9; H, 5·4; N, 3·9 per cent) and the other (from alcohol) of small prisms m.p. 208–210° (decomp.) (found: C, 64·3; H, 5·4; N, 3·8; calc. for $C_{19}H_{19}O_6N$: C, 63·9; H, 5·3; N, 3·9 per cent). A mixture of the two forms decomposed at an intermediate temperature, and they appear to be polymorphic because crystallization of the form with melting point 208–210° under appropriate conditions yields the needle form, which is slowly reconverted into the substance with the higher melting point when it is left to stand in the mother liquor.

The explanation of the change



$$\underset{|}{\overset{|}{CO}}\,\underset{|}{\overset{|}{CO}} \rightarrow \underset{|}{\overset{|}{C}}{=}\underset{|}{\overset{|}{C}}$$

in the course of the reaction between O-trimethylbrazilone and phenylhydrazine must clearly involve the propinquity of the carbonyls in the large ring structure; but the postulation of a radical change in the bonds contained in these groups is now excluded.

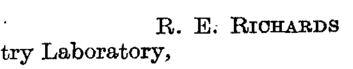
Structure of α-Fagarine

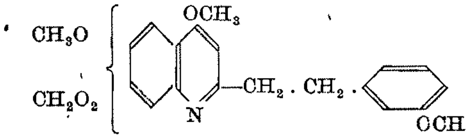
The more significant experimental facts for basing the structure of α-fagarine, one of the alkaloids isolated from *Fagara coco*[1], were the presence of one methylimino group, two methoxyls and one dioxymethylene group, and the formation of *m*-methoxybenzaldehyde by oxidation[2]. α-Fagarine behaves as a tertiary base, since it does not react with nitrous acid and also lacks rotatory power.

A tertiary base, with a methylimino group and giving *m*-methoxybenzaldehyde by oxidation, may have a structure: $R - \underset{\displaystyle CH_3}{\underset{|}{N}}.CH_2.C_6H_4OCH_3$ (*m*), as oxidation experiments with similar simpler bases have shown[3]. A substance of this type might be expected to be degraded by the action of tetranitromethane as similar bases are[4], and also by hydrogenolysis under the action of palladium-charcoal.



Fagarine was found to be resistant to both types of degradation. We believe, then, that the methylimino group, that was determined in two laboratories (in our laboratory, Slotta and Haberland's[5] method was employed) and isolated as methylamine when α-fagarine is heated with soda-lime, is an artefact. The methylimino group determined could be a resistant methoxyl that is only split off at higher temperatures than usual, or that transposes to a methylimino group under the action of the reagents. The methylamine isolated would also result from a molecular transposition.

This type of reaction could be expected from a γ-methoxyquinoline, and accordingly the following structural formula for α-fagarine is now proposed:



similar to the structures of cusparine, galipine and galipoline, all alkaloids from angostura bark, a plant belonging to the family Rutaceæ, as is the case with *Fagara coco* (Gill.) Engl., from which α-fagarine was isolated.

Thus the first formula proposed, $C_{19}H_{23}NO_4$, should be changed to $C_{21}H_{21}NO_5$. The carbon and hydrogen determinations of the free base given in our paper[2] agree well with the new formula. Fagarine salts gave lower values for carbon than those expected.

We have carried out a series of determinations of the halogens of the salts and the methoiodide of α-fagarine, which differentiate clearly between the formulæ $C_{19}H_{23}NO_5$ and $C_{21}H_{21}NO_5$, and obtained figures that agree with the last one. (Hydrochloride: calc., Cl, 8·91; found, 8·13. Hydrobromide: calc., Br, 17·85; found, 18·28. Hydroiodide: calc., I, 25·67; found, 25·64. Methoiodide: calc., I, 24·97; found, 24·47).

When α-fagarine is treated with dilute nitric acid, a nitro-derivative is obtained which gives a crystalline nitrate melting at 254–55° and of formula $C_{21}H_{20}NO_5.NO_2.NO_3H$ (calc.: C, 53·05; H, 4·21; N, 8·84; found: C, 52·85; H, 5·10; N, 8·90). This nitro-derivative gives a picrate melting at 255–57°, $C_{21}H_{20}NO_5.NO_2.C_6H_3N_3O_7$ (calc.: C, 50·54; H, 3·59; found: C, 50·53; H, 3·96).

The absorption spectrum of α-fagarine, for which we are indebted to Dr. H. Puente, also supports the quinoline structure. It presents an absorption maximum at 285 mμ and is very similar to the absorption spectrum of quinoline, with a maximum about 280 mμ, and to that of 4-quinolylmethyl ether, with a maximum about 280–285 mμ, as determined by Ewing and Steck[6]. An N-methyl quinolone structure would explain the methylimino determination and the isolation of methylamine, but leaves unexplained the formation of a methiodide and the similarity of the absorption spectrum of the base to those of quinoline and its derivatives.

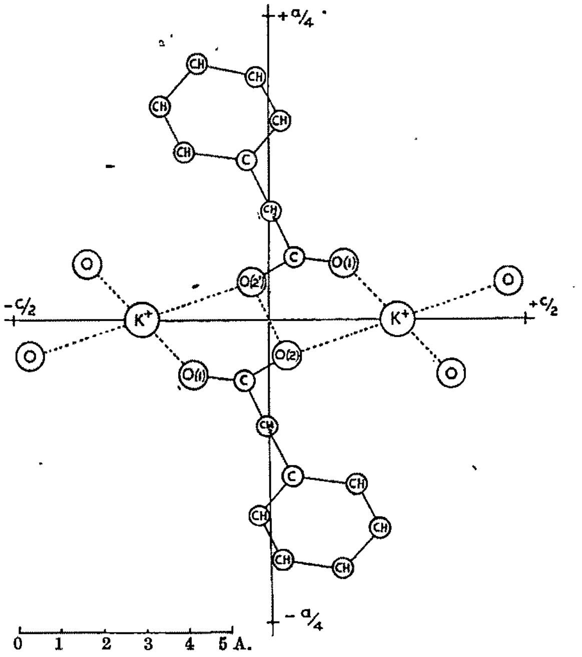
Crystal Structures of the Acid Salts of some Monocarboxylic Acids

THE crystal structure of potassium hydrogen phenylacetate, $KH(C_8H_7O_2)_2$ (a substance already discussed in another connexion[1]), has been examined by X-ray analysis. The crystals belong to the monoclinic system, the unit cell having $a = 28·4$ A., $b = 4·50$ A., $c = 11·9_7$ A., $\beta = 89·8°$ ($\pm$ 0·3°), and comprising four stoichiometric molecules. The space-group is $I\ 2/a$ (that is, $C\ 2/c$ of the International Tables with change of axes).

Using the isomorphous rubidium salt, a Patterson projection on the (010) plane indicated provisional x- and y-co-ordinates for the atoms; and, with this guidance, a corresponding Fourier synthesis has been carried out for the potassium compound. In the resulting projection, all eleven atoms of the asymmetric unit were well resolved, and the projected structure deduced is shown in the figure. Detailed consideration of this projection (and taking note of the strength of the reflexion from the (510) plane) gave a clue to the molecular orientation in the b-direction. The C—C_6H_5 group lies in a plane inclined at about 31° to (010), and the C—CO_2 group in one inclined at about 36° in the opposite direction. On this basis the complete structure has been elucidated, with some assistance from a Fourier projection on (001).



Interest is chiefly attached to the situation near he carboxyl groups. A hydrogen bond must be presumed to exist between the atoms O(2) and O(2′); and, since these atoms lie about a centre of symmetry, the hydrogen atom appears to be centrally placed. All hydrogen bonds described hitherto seem to be unsymmetrical. It is possible that the virtual symmetry found here is a statistical effect. It is difficult to determine the y-co-ordinate of O(2) very accurately, but the true distance between the oxygen toms is estimated to be $2·5_5$ ($\pm$ 0·1) A. This is nusually short (the dimers of carboxylic acids give alues of about 2·7 A.) and recalls the short bonds reported for same inorganic acid salts[2] and for the dihydrates (probably oxonium salts) of some dibasic acids[3]. Each potassium ion lies on a vertical twofold axis, and is surrounded by six approximately equidistant (~ 2·8 A.) oxygen atoms which are situated at the corners of a distorted octahedron; two pairs, O(1), are superposed, at unit b-translation, in the projection shown. A number of different valency bond structures can be written, each lacking the necessary symmetry about the origin. The actual structure is taken to be a resonance hybrid, with consequent enhanced stability.

The structure of potassium hydrogen p-hydroxybenzoate, which is also being investigated, appears to be based on the same plan. Acid salts are formed by most monocarboxylic acids, and it seems likely that they may generally conform to this plan.

Further details of both structures will be published elsewhere.

Gamma-Rays from Proton Bombardment of Separated Argon Isotopes

ARGON targets can be prepared by bombarding silver disks with the separated beams of the argon isotopes in a mass-spectrograph. This technique has already been used in a study of the resonance capture of protons in the isotopes of neon[1]. The possibility of collecting argon atoms in a metal surface has previously been demonstrated[2], and has recently been used as a method of producing samples of separated argon isotopes[3].

With the abundant isotope ^{40}A (99·632 per cent) four targets were made which had received about 55 milli-coulombs per cm.^{2} of $^{40}A^+$-ions, and in addition one target which had received about 3 milli-coulombs per cm.^{2}. For the measurements on ^{36}A (0·307 per cent) only one target, which had received about 3 milli-coulombs per cm.^{2}, was made. No target was prepared containing the rare isotope ^{38}A (0·061 per cent), due to a contamination of the ion beam of mass 38 by fluorine molecular ions. The targets were used to search for capture resonances in the two argon isotopes for protons in the energy region from 0·5 to 1·8 MeV. The techniques of proton bombardment and gamma-ray detection were the same as those used in an earlier investigation[4].

In the case of ^{40}A, six peaks were found standing out clearly above the background radiation, as determined with a dummy target. Five of these peaks are ascribed to ^{40}A. The accompanying table gives their resonance energies, and in addition the yields as measured with the four targets, which had been strongly bombarded with argon. Measurements of the resonance at 1,100 keV. with the weakly bombarded target gave half the yield, indicating that the targets are saturated with argon when they have received about 6 milli-coulombs per cm.^{2}, corresponding to about 2 μgm. per cm.^{2}. The same saturation effect has also been found in the case of neon[1]. The half-widths of the peaks were in all cases 5–10 keV.

and cannot be explained by the inhomogeneity of the proton beam, which was less than half of this amount.

E	900	1050	1080	1100	1235
$y-y_0$	0·2	0·4	0·5	1·0	0·5

E is the resonance energy in keV.; $y-y_0$ is the difference between the resonance yield y in counts per micro-coulomb and the background radiation y_0, which for all the resonances is about 0·1.

The peak remaining is ascribed to fluorine. It was found at 865 keV. and gave a yield of 0·1 count per micro-coulomb. As the ion source of the mass-spectrograph had previously been run with fluorine compounds, very small amounts of $(F_2H_2)^+$-ions may possibly have given rise to this contamination of the target. This view is strongly supported by the fact that a control target, which during the collection of ^{40}A was hit by ions of mass 38 (such as F_2^+), showed an intense resonance peak at 865 keV. and in addition the weaker fluorine lines to be expected.

It was found that the content of argon in the target gradually decreased during the proton bombardment. A new spot of the target was chosen, therefore, as soon as the yield of the 1,100 keV. resonance, which was frequently checked, decreased too much.

In the case of ^{36}A, no gamma radiation was found which could not be explained as statistical fluctuations of the background radiation. These measurements are somewhat uncertain as it was not possible to know when a spot of the target was worn out; but the experience with the ^{40}A targets was taken as a guide.

The result, that no resonances are found in ^{36}A, is in agreement with the general experience, that the mean distance between the levels of a compound nucleus, formed by impact of 1-MeV. protons on a nucleus of the α-particle type, is of the order of a few million electron volts. This fact is explained by the low excitation of the compound nucleus due to the loose binding of the incoming proton. For ^{36}A, thus, the binding energy of the proton is only about 3 MeV. At the corresponding excitation, scattering and capture of the protons are, further, the only processes energetically possible; hence the lack of gamma-resonances cannot be due to competition from other disintegrations.

The compound nucleus formed by impact of 1-MeV. protons on the isotope ^{40}A is, on the other hand, excited to about 10 MeV. and should, therefore, have many levels in the energy region investigated. The yields of the resonances are, however, for low proton energies limited by the poor penetrability of the barrier which the protons have to overcome. The proton energy at which the resonance yield begins to rise above the background is, thus, determined by the proton width.

In order to determine the proton width from the experimental data, it is necessary to calculate the absolute yield, and for that purpose to know the concentration of argon in the silver. This concentration is given by the total amount of argon in the target and the thickness of the layer containing it. The thickness can be estimated from the experimental width of the resonance peaks by means of the stopping power for protons; the natural width, for example, must be very small, in fact close to the radiation width, because the energy available for α-particle emission is too small to give an α-particle width of any importance. The relative concentration of argon to silver atoms obtained in this way is about 1 : 10. The absolute yield of the resonances can then be determined by the help of the known efficiency of the gamma-counter[4].

For the 1,100-keV. resonance this estimate gives a proton width of the order of a few electron volts, and the corresponding width without barrier is then about 10 keV., which is in accordance with the fact that the first resonance detectable was found at 900 keV. According to theory, 2π times the width without barrier should be of the order of the spacing of levels having the same spin, and this is roughly in agreement with the experiment, as at 1 MeV. only protons of angular momentum zero can penetrate the barrier sufficiently easily to be responsible for the resonances found.

The lack of resonances when the energy exceeds 1,235 keV. can be explained as the passage of the threshold energy for neutron emission, because above this energy the radiation processes are unable to compete with the neutron emission process. The threshold energy of the protons, calculated from the masses, is 1 MeV.; but the uncertainty is about ± 1 MeV. The experimental threshold is not necessarily equal to this value, because the conservation law for the angular momentum may force the neutrons to penetrate a centrifugal barrier, and thus make neutron emission improbable. As the spin is not known for all the nuclei concerned, the experiment cannot be used to determine the binding energy of the neutron in the compound nucleus with higher accuracy than that with which it is already known A direct detection of the neutrons is practically impossible even at higher excitation energies, because of the low efficiency of neutron counters.

It is seen that the experiments are in qualitative agreement with the theoretical expectations.

In conclusion, we wish to thank Prof. Niels Bohr for his continuous interest in the work.

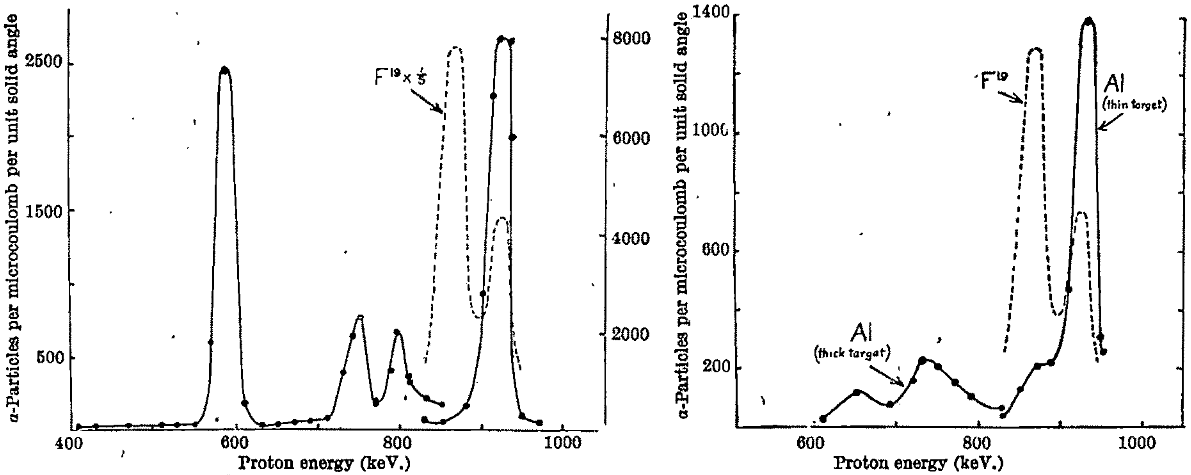
Short-Range α-Particles from the Disintegration of Sodium, Aluminium and Fluorine by Protons

THE emission of short-range α-particles in th proton bombardment of oxygen, nitrogen and fluorin has been known for some time[1]. Calculations base on published mass values[2] show that there shoul also be a release of energy in the (p,α) reactions i sodium and aluminium, according to the equations

$$Na^{23} + H^1 \rightarrow Ne^{20} + He^4 + Q_1 \qquad (1)$$

$$Al^{27} + H^1 \rightarrow Mg^{24} + He^4 + Q_2. \qquad (2$$

These processes have now been observed, and the Q-values obtained, by a method of magnetic analys similar to that used by Burcham and Devons[3] fo the detection of the short-range α-particles in th proton disintegration of fluorine. Some furthe observations on this latter reaction have also bee made.



(a) Sodium chloride (thin target)

(b) Aluminium

Fig. 1. Excitation functions for sodium and aluminium (p,α) reactions. The absolute value of the ordinates is approximate only. In (a), left-hand and right-hand ordinates refer to the curves for proton energies below and above 830 keV. respectively

Disintegration particles emitted at 90° to the proton beam were allowed to pass through a 90°-focusing magnet, so that the α-particles could be resolved from the longer-range scattered protons. The α-particles were focused on to a zinc sulphide screen and the resulting scintillations were detected by an E.M.I. photo-electric multiplier. For accurate range measurements the screen and multiplier were replaced by a mica window of 2 mm. stopping power, and a shallow air-filled ionization chamber placed at a variable distance from the window. The range scale was calibrated with α-particles from a thin thorium-C source.

The yield of α-particles from reactions (1) and (2), observed as a function of incident proton energy, is shown in Figs. 1(a) and 1(b). For comparison, α-particles from the reaction:

$$F^{19} + H^1 \rightarrow Ne^{20*} \rightarrow \left.\begin{array}{l} O^{16*} + He^4 + Q_3 \\ O^{16*} \rightarrow O^{16} + \gamma \end{array}\right\} \quad (3)$$

were also observed; the excitation function thus obtained was compared with the well-known excitation function for the γ-rays in this reaction[4,5], in order to calibrate the proton energy-scale. The yield of fluorine α-particles for proton energies from 830 to 950 keV. is shown by the broken curves in Fig. 1.

The ranges of the α-particles emitted in the sodium and aluminium reactions (1) and (2) were measured by direct comparison with the range of α-particles from the fluorine reaction (3), for which an absolute measurement had previously been made (1·11 cm. at 930 keV.). Fig. 2 shows the ionization chamber measurements for the case of aluminium. The mean ranges for sodium and aluminium α-particles were found to be 1·38 cm. and 1·00 cm. respectively, at 930 keV. proton energy.

In the course of the work on fluorine, α-particles of slightly greater range than that associated with reaction (3) were also observed, at a proton energy of 830 keV. These are attributed to the process:

$$F^{19} + H^1 \rightarrow Ne^{20*} \rightarrow \left.\begin{array}{l} O^{16*} + He^4 + Q_4 \\ O^{16*} \rightarrow O^{16} + \pi \end{array}\right\}, \quad (4)$$

in which the excited state of O^{16} reverts to the ground-state with the emission of an electron pair. A pair-production resonance at 830 keV. is known[4,6]. The Q-value deduced from this process agrees well with the measurements of Becker *et al.*[7] at the 1,220-keV. pair-production resonance.

The Q-values for reactions (1) to (4), calculated from the range measurements by using the 1938 Cornell range-energy curve for α-particles, are:

$Na^{23}\ (p,\alpha)\ Ne^{20} : Q = 2\cdot14 \pm 0\cdot07$ MeV.
$Al^{27}\ (p,\alpha)\ Mg^{24} : Q = 1\cdot32 \pm 0\cdot07$,,
$F^{19}\ (p,\alpha\gamma)\ O^{16} : Q = 1\cdot73 \pm 0\cdot05$,,
$F^{19}\ (p,\alpha\pi)\ O^{16} : Q = 1\cdot89 \pm 0\cdot06$,,

The difference between the γ-ray and pair-production states in the two fluorine processes could be determined, by direct comparison, more accurately than either value individually, and is 0·16 ± 0·02 MeV. The Q-value found for the $F^{19}(p,\alpha\gamma)O^{16}$ reaction upon which the sodium and aluminium results depend is in fair agreement with other measurements[7,8].

If it is assumed that the α-particles observed from sodium and aluminium are associated with the formation of the residual nucleus in its ground-state, then the Q-values found provide fresh data for the cal-

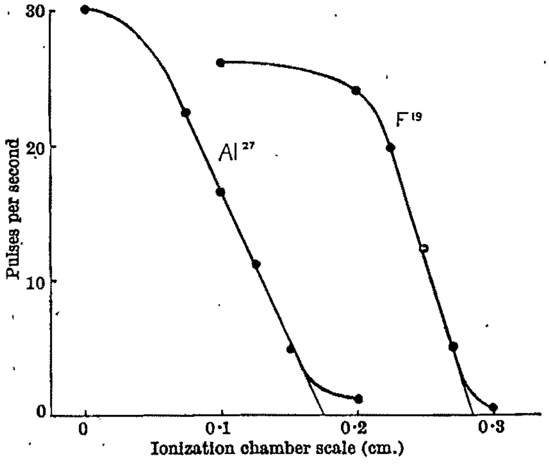


Fig. 2. Comparison of ranges of α-particles from Al^{27} and F^{19} at 930-keV. proton energy. Ordinates (scales arbitrary) represent counting-rates of pulses greater than a given size determined by the discriminator bias

culation of the masses of the nuclei Mg^{24} and Na^{23}. The values obtained fit very well into the scheme of mass values suggested for the elements between neon and silicon by Allan and Wilkinson[9].

The capture of protons by sodium and aluminium may alternatively result in the emission of γ-rays with sharply defined resonances for varying proton energy[10-12]. The inhomogeneity of the proton beam used in the present experiments makes it difficult to establish with certainty any connexion between α-emitting and γ-emitting levels of the compound nucleus concerned.

The work is continuing and further details will be published later.

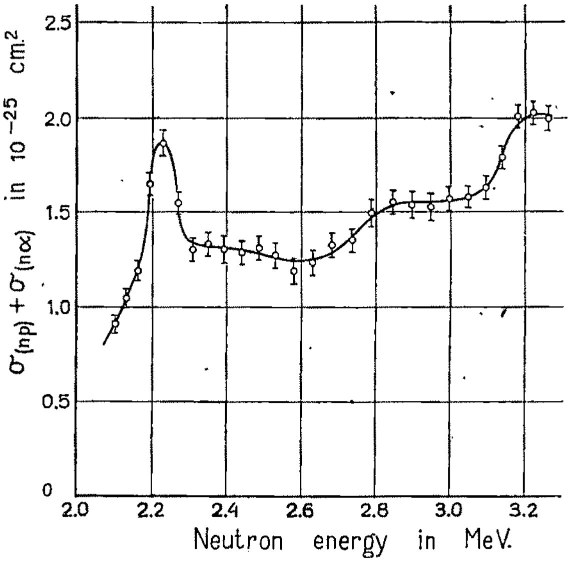
Disintegration of Nitrogen by Fast Neutrons

THE reactions $^{14}_{7}N\ (np)\ ^{14}_{6}C$ and $^{14}_{7}N\ (n\alpha)\ ^{11}_{5}B$ have been investigated using the mono-energetic neutrons, obtained by bombarding a thin heavy-ice target by deuterons (D+D neutrons). With a deuteron energy of 400 keV. and a variation of the angle between the direction of the neutrons used and the beam of impinging deuterons from 34° to 138°, the neutron energy is varied between 3·2 and 2·1 MeV. This method was suggested to me by Dr. Hl. de Vries. The number of (*np*) and (*nα*) reactions is measured in a nitrogen-filled proportional counter, which is placed in various positions in the above-mentioned interval, with respect to the target. In order to eliminate fluctuations in the yield of the neutron source, the number of kicks from this counter is divided by the number of counts given in the same time by a proportional counter filled with boron fluoride which is kept in a fixed position. For the calculation of the cross-sections, the absolute number of neutrons getting into the nitrogen counter must be known. Therefore the number of neutrons per unit of solid angle in the direction of the boron fluoride counter for a given number of counts was determined from the response of this counter to a source consisting of 90 mgm. radium + beryllium, placed close to the target. For other directions this number was calculated, assuming the $(1 + A\cos^2\theta)$-law in the centre of gravity co-ordinate system, with $A = 1{\cdot}5$ in this case[1].

The cross-sections obtained are represented in the accompanying figure as a function of the neutron energy. The peak indicates a resonance for 2·23 MeV. neutron energy, corresponding to an excited state of the intermediate $^{15}_{7}N$ nucleus. The height of this level above the ground-state is 12·87 MeV., which is easily calculated with the help of the mass values[2]. Other possible irregularities in the curve are being studied in more detail. Other resonances have been found in the region between 0·2 and 1·7 MeV. neutron energy by Barschall and Battat[3], using mono-energetic neutrons, (Li + *p*) reaction, namely, at 0·55, 0·70 and 1·45 MeV.



The combined cross-sections for the (*np*) and (*nα*) reactions in nitrogen as a function of the neutron energy. Only statistical errors have been plotted

The other way in which fast neutron resonances have been studied is by the method, first applied by Wilhelmy[4], in which a neutron source with continuous energy distribution is used, and groups of protons and α-particles of different energies are observed. The relation between the energies of such groups, and those of the corresponding resonance neutrons, is given by the energy balance of the (*np*) and (*nα*) reactions:

$$E_{p,C} = E_n + Q_1;\quad E_{\alpha,B} = E_n + Q_2,$$

in which $E_{p,C}$ means the sum of the kinetic energies of a proton and the residual carbon nucleus (measured by Wilhelmy's method), etc. If the residual nucleus is in the ground-state, the *Q* values are equal to the mass differences in MeV. According to the latest measurements $Q_1 = -0{\cdot}24$ MeV.; $Q_2 = 0{\cdot}63$ MeV.[5].

Stebler and Huber[5], calculating resonance neutron energies from their groups in this way, find the values 0·48, 0·64, 1·41, 1·77 and 2·20 MeV., in good agreement with our value (2·23 MeV.) and those of Barschall and Battat (0·55, 0·70 and 1·45 MeV.).

If we also calculate those resonance neutron energies from earlier measurements which lay within our region, we find: 2·28, 2·83, 3·45 MeV. (Wilhelmy[4]); 2·38, 2·75, 3·24 MeV. (Ortner and Protiwinsky[6]); 2·18, 2·39, 2·88, 3·22 MeV. (Zagor and Valente[7]). The lowest value of each series may be identified with our value and the corresponding one of Stebler and Huber. There is some indication in our measurements also for the highest resonance of about 3·30 MeV. The resonance at about 2·83 MeV., on the contrary, does not appear clearly in our curve. This does not necessarily mean a discrepancy, however, as the authors mentioned used neutrons up to high energies. Therefore excited states of the residual nucleus may occur, giving other groups which cannot be found in this experiment.

Absorption measurements. As Valente and Zagor[8] find for the total cross-section of their resonance neutrons the exceedingly high value of 60×10^{-24} cm.^{2}, we made absorption measurements in the region of the maximum with dicyandiamide ($C_2H_4N_4$) which resulted in a value for the total cross-section of about 2×10^{-24} cm.^{2}. Thus, as contrasted with the results of Valente and Zagor, we may conclude that no real conflict with theory seems to exist for these neutrons.

I wish to express my thanks to Prof. D. Coster for suggesting the problem and for his interest in the work, and to the "Stichting voor fundamenteel onderzoek der materie" for financial support.

A Magnetic Resonance Accelerator for Electrons

IN his paper, "A New Method of Acceleration of Relativistic Particles", Veksler[1] proposed two methods of overcoming the limitation of the cyclotron due to he relativistic increase of the mass of the particle. One of these is the synchrotron, now well known; and the other, which has been called the microtron[2] and is essentially an electron cyclotron, is the subject of the present note.

We have constructed a small electron accelerator to operate on this principle, and have observed that he electrons are accelerated in the expected manner. The radio-frequency voltage on the accelerating gap s between 500 and 600 kV., and the magnetic field about 1,000 oersteds. The electrons make eight uccessive passages across the gap and have a final energy of 4·6 MeV. Further acceleration is at present limited by the size of the magnet.

Veksler pointed out the very important fact that for a relativistic particle subject to periodic accelerations the difference in the time required to execute successive orbits in a magnetic field is a constant, and independent of the total energy of the particle. In an accelerator which makes use of this fact, H, the magnetic field, and V, the radio-frequency voltage, are adjusted so that the time difference between uccessive orbits is equal to T, the period of the adio-frequency field. This defines the resonance ondition:

$$\frac{2\pi V}{HC} = T. \tag{1}$$

Further, for the particle to be in resonance with the radio-frequency field, Veksler showed that the itial energy of the particle must be such that:

$$\frac{2\pi M_0 C}{He}(k+1) = T\gamma, \tag{2}$$

where $k = V_k/M_0C^2$ is the energy in mass units of the particle before acceleration by the radio-frequency eld, and γ is an integer.

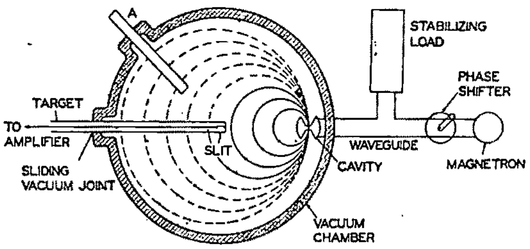

Fig. 1

The accelerator takes the form shown in plan in Fig. 1. A cavity resonant at $\lambda = 10{\cdot}7$ cm. is contained in one side of a vacuum chamber placed between the poles of an electromagnet. Power is fed to the cavity through an evacuated wave-guide from a tunable magnetron. A stabilizing load and phase shifter operating in vacuum allow the adjustment of the loading of the magnetron.

Geometrical considerations limit the length of the accelerating gap in the cavity, and we have chosen a 1-cm. gap as a compromise between poor geometry and lower shunt resistance. The cavity is an ellipsoid hyperboloid cavity, the electrical characteristics of which have been calculated by Hansen[3]. With a 1-cm. gap the theoretical constants are $Q = 12{,}000$; $R_s = 2{\cdot}2 \times 10^6$ ohms. The poles of the cavity are flattened and pierced with ¼-in. diameter holes.

The following considerations made it appear probable that the condition (2) on the initial energy could be satisfied without attempting to control the injection energy, but rather by using the electrons which originate within the cavity itself. Preliminary experiments with such a cavity showed that this current was about 20 m.amp. peak value. A theoretical study of the passage of the electron across the gap showed that for an electron starting from rest across a 1-cm. gap the process is quite efficient, and for starting phase angles from 40° to 80° in the radio-frequency cycle the electron acquires an energy within a few per cent of the peak voltage on the gap. If, therefore, the gap voltage is equal to the rest mass of the electron in electron volts, both conditions will be fulfilled by electrons starting from rest; that is, $k = 0$ in (2). For phase stability in succeeding orbits it is necessary that the electron crosses the gap beyond the peak of the radio-frequency cycle, the centre of the phase-stable region being at about 100°. It therefore seemed probable that the electrons starting from rest in the region of 60° and having a transit angle of 54° would enter the phase-stable region of the radio-frequency cycle and be subjected to further accelerations.

To observe the orbits, which are the family of circles shown in Fig. 1, a target is mounted on a sliding vacuum seal on the opposite side of the vacuum chamber from the cavity, and is coated with fluorescent material to show the position of the orbits visually. With power being fed to the cavity and the magnetic field adjusted to the resonance value, the various orbits can be seen by slowly withdrawing the fluorescent target. As the target is withdrawn until an orbit just clears it, the next one appears at once. This is evidence that the orbits are circular and passing through the accelerating gap. That such is the case has been verified by placing adjustable obstructions at other points such as A.

The fluorescent target is also fitted with an insulated Faraday collector behind a 1-mm.-wide lead slit to record the electron current. The current is

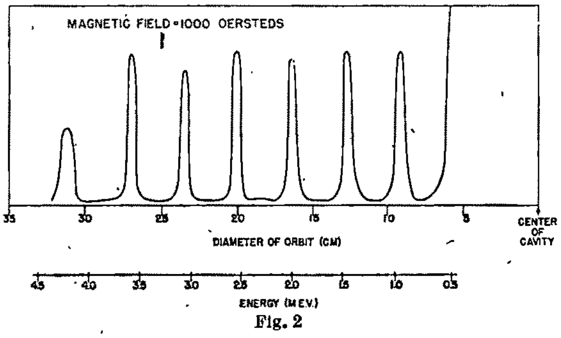

Fig. 2

amplified and fed to a recording meter. Fig. 2 shows a typical plot of the current collected as a function of the distance from the slit to the centre of the cavity. Although the eighth orbit appears broadened due to its proximity to the edge of the magnetic field, there is little, if any, loss of current between orbit 2 and orbit 8.

Instead of the sharp resonance at 1,000 oersteds to be expected from (1) and (2), the resonance value of the magnetic field is found to be broad, and with a particular cavity eight successive orbits are obtained for values of the magnetic field anywhere between 900 and 1,200 oersteds. We have no adequate explanation of this, but believe it is connected with the possibility that electrons with the required phase may cross the first gap with a range of energies. In this way it is possible to satisfy (1) and (2) simultaneously for a range of magnetic fields. It may be possible to make use of this phenomenon in future designs to permit the use of higher magnetic fields and cavity voltages.

In addition to the main resonance, other modes of resonance operation at lower magnetic fields are also observed. These may be identified with the resonance conditions when $\gamma = 2, 3, 4, \ldots$, and the time difference between successive orbits is $2T, 3T, 4T, \ldots$

Sea Waves and Microseisms

It is well known[1] that the pressure variations beneath a progressive gravity wave of Stokes's type are insufficient, in deep water, to generate microseisms of the observed magnitude. This is because the pressure variations on the sea-bed decrease exponentially with the depth. The following argument, however, shows the existence, in a general class of wave motions, of 'second-order' pressure variations which are not attenuated with the depth.

The surface elevation in a simple stationary wave, for example, is given, in Lamb's notation[2], by

$$(A) \qquad \eta = a \cos kx \cos \sigma t + O(a^2),$$

where

$$\sigma^2 = gk \tanh kh.$$

Consider the mass of water contained between the bottom $z = -h$, the surface $z = \eta$ and the two vertical planes $x = 0, \lambda$ where $\lambda = 2\pi/k$. There is no flow across the vertical planes and therefore this mass o water consists always of the same particles. Therefore, if F is the vertical component of the total externa force acting on the mass, we have, summing the equations of motion for each particle of mass m and cancelling internal forces,

$$F = \Sigma\, m \frac{d^2 z}{dt^2} = \frac{1}{g} \frac{d^2}{dt^2} \text{ (potential energy).}$$

Now the forces across the vertical boundaries contribute nothing to F; the pressure p_0 at the fre surface contributes a downwards force λp_0 an gravity a constant force $\lambda \rho g h$. Hence

$$F = \lambda(p - p_0 - \rho g h),$$

where p is the mean pressure on the bottom. Now for the stationary wave (A) we have, neglectin compressibility,

$$\text{potential energy} = \int_0^\lambda \tfrac{1}{2} \rho g \eta^2 \, dx$$

$$= \tfrac{1}{4} \lambda \rho g a^2 \cos^2 \sigma t + O(a^3)$$

Hence

$$(B) \qquad \frac{p - p_0}{\rho} = gh - \tfrac{1}{2} a^2 \sigma^2 \cos 2\sigma t + O(a^3).$$

The second term is of order (wave-height)², whic explains why it is not revealed in the ordinary first order theory. It is also of double the fundamenta frequency and, for a given frequency and amplitude is independent of the depth h. Equation (B) has bee derived by Miche[3] in the course of a complet evaluation of the second approximation to th stationary wave-motion. By a slight extension o the present argument one can evaluate the mea pressure below the series of long-crested waves give by

$$(C) \qquad \eta = \sum_{m,n} a_{m,n} \cos (mkx + nky + \sigma_{m,n} t + \varepsilon_{m,n})$$

where m and n are integers and

$$\sigma_{m,n}^2 = (m^2 + n^2)^{1/2} gk \tanh (m^2 + n^2)^{1/2} kh, \quad (\sigma_{mn} \geqslant 0$$

If p is the mean pressure on the bottom, we find

$$(D) \qquad \frac{p - p_0}{\rho} = gh -$$

$$\sum_{m,n} a_{m,n}\, a_{-m,-n}\, \sigma_{m,n}^2 \cos (2\sigma_{m,n} t + \varepsilon_{m,n} + \varepsilon_{-m,-n}$$

Hence this type of pressure fluctuation occurs whe ever wave-trains cross which are of the same fr quency and travel in opposite directions (correspon ing to integers (m,n), $(-m,-n)$). A single wav train gives zero fluctuation in the mean pressure.

These results provide the basis for a new theory microseism generation. They explain how micr seisms come to be generated in deep water[4,5], an why the frequency of the microseisms is sensib double that of the waves associated with them The theoretical orders of magnitude are in agreeme with those observed. A fuller account of the theor is in preparation.

Spreading Phenomenon and Inflammation

A STUDY has been made of the spreading activity of certain inflammatory agents in rabbit skin. As the results of this work may be of general interest, a brief account of them are given here.

Using hæmoglobin as an indicator of spreading, it has been found that the intradermal injection of inflammatory agents into the shaved skin of anæsthetized rabbits produces significant spreading as compared to saline controls. The agents investigated (concentration in mgm. per c.c.) were the following: trypsin (10), chymotrypsin (10), 'Bactopeptone' (100), Wittes' peptone (100), casein digest (100), $\frac{1}{2}$–$\frac{1}{4}$ saturated urea, and snake venoms (0·1) (copperhead, diamondback rattlesnake and mocassin), wherein the hyaluronidase originally present was destroyed by treatment with alkali[1].

The spreading observed with these inflammatory agents differs from that produced by hyaluronidases in that the rate of spreading is slow and the injected bleb persists as spreading proceeds. When these agents are injected into the skin of recently killed rabbits, where inflammatory œdema cannot occur, no spreading response is observed. This demonstrates that inflammatory agents do not directly alter the permeability of the dermal barrier to fluid diffusion. To determine whether the inflammatory agents acted via liberation of 'bound' hyaluronidase in skin[2], the effect of a hyaluronidase inhibitor upon the spreading activity of inflammatory agents in live rabbits was evaluated. Nitrated and partially de-esterified nitrated hyaluronates which markedly reduce hyaluronidase viscosity-reducing activity by competitive inhibition[3] were used in these experiments. It was observed that whereas the spreading activity of purified testis hyaluronidase or of snake venoms containing hyaluronidase was either inhibited or abolished by the inhibitors, the spreading activity of these inflammatory agents uniformly was not affected.

The mechanism by which inflammatory agents produce spreading in skin is explicable in terms of simple mechanical forces. It has previously been found that the area of spread produced by saline – hæmoglobin mixtures is proportionate to the volume of fluid injected, or on the interstitial fluid pressure of the bleb[2]. Since inflammatory agents produce œdema consequent to capillary damage in the injected area, this increases the interstitial pressure of the bleb, thus giving rise to greater spreading than is observed with the saline control. This view explains why the injection bleb persists (or even becomes higher), in association with spreading of the indicator, with these agents in contrast to the spreading seen with hyaluronidase or saline, where the bleb flattens as spreading proceeds. It should be emphasized that the permeability of the dermal barrier need not be affected in these acute inflammatory spreading reactions.

These findings may provide an explanation for the fact that diverse agents ranging from simple chemicals like arsenious oxide to biological factors present in some bacteria and venoms, while without influence upon hyaluronic acid *in vitro*, nevertheless possess significant spreading activity *in vivo*[4]. The suggestion is advanced that these spreading factors, some of which are known to be inflammatory agents, act via the capillary damage they induce. In this connexion, it may be important to note that the spreading activity of extracts of rabbit organs such as spleen, lung, and liver (prepared according to the method of Claude and Duran-Reynals[5]), is similar to the inflammatory agents studied, in that the slow spread obtained with these tissue extracts is not inhibited by nitrated hyaluronates, and the spreading response is absent, in the skin of dead rabbits.

In previous studies it was demonstrated that inflammatory agents present in snake venoms markedly increase the final area of spread produced by purified testis hyaluronidase[1]. It has now been observed that this augmentation of spread can be duplicated by non-specific inflammatory agents such as concentrated urea and peptones. In experiments where a constant hyaluronidase concentration was injected with variable concentrations of inflammatory agents (peptones, proteolytic enzymes and alkali-treated snake venoms), it has been observed that the final area of spread is proportional to the concentration of inflammatory agent employed.

These studies illustrate the importance of inflammation in spreading phenomenon and may have implications for local bacterial invasiveness. It would appear that bacteria which do not produce hyaluronidase may spread extensively, although less dramatically than hyaluronidase-producing organisms, via the inflammatory changes they induce. The invasiveness of hyaluronidase-producing bacteria may depend quantitatively upon the degree and character of the inflammation they induce, and only secondarily upon the concentration of hyaluronidase produced *in situ*.

Full details of these studies will be published elsewhere. This work was aided in part by a grant from the G. D. Searle Company.

Destruction of Urinary Glucuronide by Bacteria

IN a recent publication, Senior[1] has emphasized the importance of the preservation of rabbit urine preceding estimations of its glucuronide content. This point has been previously made by, for example, Venning[2] and by Bucher and Geschickter[3] with regard to pregnanediol glucuronide in human urine, and has lately been further investigated[4].

We have carried out experiments to try to determine what organisms may be responsible for the apparently complete destruction of 'pregnanediol-like-glucuronide'[4] which may occur in unpreserved human urine. We have found that, whereas a number of common bacteria were without effect on this substance, its destruction, as well as that of added sodium pregnanediol glucuronidate, occurred when certain strains of *Staph. albus* were grown in sterile urine containing the glucuronide. Our experiments suggest that more than a simple hydrolysis of the glucuronide may be involved in the action of the organism, for we have not always been able to detect glucuronic acid itself, which should be present after hydrolysis.

Staph. albus might occur as a contaminant of urine collected in the usual way. Our work, however, does not show that this organism is the only common one which may be concerned in glucuronide destruction, and we are at present engaged in a more systematic search for bacteria of the glucuronide-destroying type.

Intermediates in Soil Nitrification

ON somewhat indirect evidence, the theory has been put forward[1,2] that hydroxylamine is an intermediate in the first stage of soil nitrification, that is, the stage in which ammonium ions are oxidized to nitrite ions. I have now tested this theory directly by making use of the observation[3] that fresh soil percolated with an ammonium salt and potassium chlorate produces no nitrate but only nitrite, because the chlorate ion selectively inhibits the proliferation of the nitrite-oxidizing micro-organisms. It therefore follows that if hydroxylamine is an intermediate in nitrite formation, a soil percolated with hydroxylamine and chlorate should produce nitrite in the percolate. Because the colorimetric estimation of very low concentrations of nitrite is simple and certain, the hydroxylamine may be tested at very low concentrations and its possible toxic effect[4] minimized.

The soil percolators[5] were actuated by a stream of air, previously sterilized and freed from traces of ammonia by passage through $M/50$ copper sulphate in $M/50$ sulphuric acid, fed in through the bubbler tubes. In these percolators, 10-gm. lots of the crumb layer of San Juan chocolate soil (air-dried and sieved 4·0 mm.–1·0 mm.) were percolated for 24 hours with 100 ml. distilled water. This wash percolate was then discarded, and the soils repercolated with 100 ml. of either $M/10,000$ potassium chlorate, or $M/10,000$ potassium chlorate containing ammonium sulphate and/or hydroxylamine. Parallel tests were also run with hydrazine in place of hydroxylamine, hydrazine being another possible intermediate. All nitrogen compounds were added to a concentration of 7 μgm. nitrogen per ml. percolate. After five hours of test percolation, the nitrite concentrations of the percolates were determined by the Griess – Ilosva reagent. The results are given in the accompanying table.

These results do not prove that neither hydroxylamine nor hydrazine is an intermediate in the first stage of soil nitrification; they suggest that neither compound acts as such when added extracellularly. It is possible, for example, that neither compound can penetrate the cell wall, or that both are destroyed by other soil reactions before they can reach the nitrifying cells.

Nitrite formation by 10 gm. lots of San Juan soil percolated wit 100 ml. $M/10,000$ potassium chlorate with or without the additio of various nitrogen compounds at concentrations of 7 μgm. N/ml

Nitrogen compound added to percolate	Nitrite–nitrogen concentration o percolate after 5 hours percolatio (μgm. N/ml.)			
None	$<0·01$	$<0·01$	$<0·01$	$<0·0$
Ammonium sulphate	0·26	0·26	0·26	0·2
Hydroxylamine hydrochloride	$<0·01$	$<0·01$	$<0·01$	$<0·0$
Hydrazine sulphate	$<0·01$	$<0·01$	$<0·01$	$<0·0$
Hydroxylamine hydrochloride plus ammonium sulphate	0·26	0·26	0·26	0·3
Hydrazine sulphate plus ammonium sulphate	0·29	0·29	0·27	0·2

If it is true, however, that hyponitrite is an intermediate[6] and that carbon dioxide is essential in soi nitrification[7], then there is a distinct possibility tha the first *recognizable* step in nitrification in soil i the dismutation of ammonium bicarbonate into hyponitrite and formaldehyde :

$$NH_4HCO_3 \rightarrow HNO + H_2O + H.CHO.$$

This equation is tentative and lacks experimenta proof; but the similarity it bears to the 'basic' equation of photosynthesis is interesting in view o Godlewski's suggestion[8] that the energy released by ammonium oxidation by the nitrifying organism replaces that captured by the photosynthetic proces in photosynthesizing organisms.

Nomenclature of the British Littorinidæ

THE currently accepted classification of the Britis Littorinidæ (= Lacunidæ) is that of Winckworth[1] In his earlier publication[2] on the nomenclature o this group, Winckworth assigns the species formerly included under *Littorina*, on the basis of difference in the methods of reproduction, to four genera, thus (1) *L. littorea* (L.) to *Littorina* Ferrusac, (2) *L. saxatili* (Olivi) to *Littorivaga* Dall, (3) *L. neritoides* (L.) t *Melarhaphe* Menke and (4) *L. obtusata* (L.), *L* *æstuarii* (Jeffreys) and *L. littoralis* (L.) to *Neritoide* Brown (the occurrence of *obtusata* in Great Britai being, however, thought doubtful). "It has long bee known that *L. littorea* has pelagic egg-capsules an passes through a free Veliger stage, while *L. rudi* is viviparous and *L. littoralis*, like the species o *Lacuna*, deposits eggs in oothecæ on the seaweeds.' To the objection that these differences are ecologica and should have no place in a classification base on morphology, Winckworth's reply was: "Th closest groups are *Littorina* and *Neritoides* and to m mind the distinction between a Mollusc with a fre Veliger stage and one that does not pass through thi stage still remains of generic importance, while i ther groups the genera could be separated on natomical and conchological distinctions. Those ho do not see with me in this may regard the names s of a sub-generic rank." Accordingly, in his later ublication[1], he treats *Littorivaga, Melarhaphe* and *eritoides* as sub-genera of *Littorina*, without any rther discussion.

In a previous communication[3], I reported the occurence of oviparity in some of the so-called varieties f *L. saxatilis* (a species that has always been condered to be viviparous) at high-tide levels on the ore at Cullercoats, and suggested that these thin-elled *rudissima* forms should be regarded as disnct from the thick-shelled *rudis* forms as well as om the other viviparous varieties and sub-species f *L. saxatilis*. Further studies have, however, vealed that while the *rudis* forms are always viviarous and distinct, a small proportion of the thin-helled animals which are otherwise indistinguishable om the oviparous ones do contain shelled embryos the uteri. One is led to the conclusion that here a case of the same species exhibiting both the viparous and the viviparous modes of reproduction ven in the same locality.

A careful study of the available literature has also vealed that such cases of pœcilogony have already een recorded among the Gastropods. Pelseneer[4] tates: "There is no clear demarcation between the viparity proper of the generality of Molluscs and voviviparity which is realized in some of the specialed forms", and gives several instances where the ame species may reproduce either by the one or e other method according to circumstances (for xample, *Helix carthusiana, Achatina panthera, Balea erversa*). Regarding the stage of emergence from he egg-capsule and the duration of free larval life, so, variations are possible within the same species. horson[5] mentions the case of *Brachystomia rissoides*, hich varies both in egg-size and in the larval deelopment (pelagic or non-pelagic) from place to ace. The same author also describes examples *lanaxis sulcatus, Natica catena*, etc.) in which the nbryos may hatch at any time and in any stage f development depending upon the quantity of ourishment ('nurse-eggs') available to them in the g-capsules, and a planktonic larval phase may or ay not be present according as the 'nurse-eggs' are w or plentiful. These 'nurse-eggs' may vary conderably in number in a given species not only from ace to place but also within the same locality. In e case of *Thais hæmastoma*[5], 'nurse-eggs' may be mpletely absent in one place while present in other, a planktonic larval stage being present in e former but not in the latter. Finally, there are e observations of Tattersall[6] on the hatching of *obtusata* (= *L. littoralis*, according to Colman[7]) der laboratory conditions in south-western Ireland; hile a planktonic stage is known to be absent in this ecies, in this particular case the eggs hatched out late veligers and had a short planktonic phase. lman[6], who repeated the experiment in fingerwls at the Plymouth laboratory, found that the ung ones hatching out of the egg-capsules "always awled out and never swam". He concludes: "All at can be said from these observations is that under ughly similar laboratory conditions there was a tinct and important difference in the hatching ges of *L. obtusata* from South-western Ireland and m Church Reef".

In the light of the circumstances summarized ove, it may be suggested that the (generic or) sub-generic differences recognized by Winckworth are not valid. A fuller discussion will be published elsewhere along with the details of the work on *L. saxatilis*.

My thanks are due to Prof. A. D. Hobson, under whose supervision this work has been carried out.

Ustilago microchloæ: a New Record

RECENTLY, Dr. H. F. Mooney collected some grasses from the sandy soil around Angul, Orissa. These were sent to me in the ordinary way for naming at Kew. The specimens were 4–7 cm. high, and were peculiar in that each stem terminated in a dark fruit-like swelling. These were due to a smut *Ustilago microchloæ* Syd. et Butler, the host plant being *Microchloa indica* (Linn. f.) Beauv. (syn. *Microchloa setacea* R. Br.). As no material of the smut was available for comparison at the Kew Herbarium or at the Commonwealth Mycological Institute, Kew, a request was sent to Stockholm for a loan of the type specimen in Sydow's herbarium. This was made available through the courtesy of Dr. Arwidsson of the Naturhistoriska Riksmuseet, and the provisional identification of *Ustilago microchloæ* was confirmed. A point of interest in this smut is that the whole inflorescence, which is usually 5–7 cm. long in normal plants, is replaced by one fruit-like ovoid body of only 2 mm. in diam. This is packed with soot-like smut spores. By further correspondence I was able to secure additional specimens which are being distributed to Kew, New Delhi, Stockholm, Paris, Farlow Herbarium, Cambridge, Mass., and the U.S. Department of Agriculture, Washington, D.C.

This smut was first collected by Butler on September 19, 1903, at Bilikere in Mysore, and was described by Sydow and Butler[1] in 1906. This collection was cited by Butler and Bisby[2] in 1931; but I am not aware of any further gathering until the present one by Mooney (August 18, 1948). The latter appears to be the first record for Orissa and extends the known range of the species several hundred miles to the north-east of Mysore. Mooney says: "the grass is very inconspicuous and ephemeral and seemingly rarely collected". The present plentiful gathering is therefore valuable in allowing distribution of this rare and interesting species, besides giving a new record for Orissa.

Resistance to the Potato-Root Eelworm

SINCE 1941, I have been testing South American tuber-forming *Solanum* species for immunity and resistance to the potato-root eelworm. The material, kindly supplied by Dr. P. S. Hudson and Dr. J. G. Hawkes, of the Commonwealth Bureau of Plant Breeding and Genetics, Cambridge, forms part of the Commonwealth Potato Collection[1]. An interim report on this work was published in 1945[2], when about fifty forms had been examined. Since then, however, owing to a grant from the Commonwealth Agricultural Bureaux, it has been possible to increase the scale of the tests, and about seven hundred forms have now been examined.

The plants are grown in duplicate, in pots of infected soil sunk in the field. At the end of the season, the roots are examined in the field for eelworm cysts. Only in the case of a single type has this examination failed to reveal cysts; in 1945, no cysts were found on either of the extensive root systems of two well-grown specimens of *S. Ballsii*. The same result was obtained with two plants of the same species tested in 1946; however, while microscopic examination of roots stained with acid fuchsin had revealed no larvæ in the roots of the 1945 specimens, larvæ were found in 1946. More material was available in 1947 and tests were carried out on eleven plants. Again no cysts were found in the field; but on this occasion microscopic examination revealed the presence of a few very small cysts on the roots of some of the plants.

I have already referred to the difficulty of assessing relative resistance[2], and my subsequent work has emphasized this[3]. Nevertheless, the conclusion seems amply justified that, whereas *S. Ballsii* is not immune, it does appear to be exceptionally resistant. Mai and Lownsbery, of Cornell, have kindly allowed me to state that their preliminary trials with this form tend to support this finding.

'Weeding' in Fish-Farming

THE papers by Dr. C. F. Hickling in *Nature* of May 15 and by Messrs. L. H. N. Cooper and G. A. Steven in *Nature* of April 24 are related. In particular is this so in the case of 'weeding'.

In the Far East, fish culture by the peasants is traditional, either in inland waters or in enclosed areas 'bunded off' from the sea. I will give two examples of how 'weeding' is dealt with, at the peasant level, for these people have been faced for countless generations with the same problems that Messrs. Cooper and Steven discuss at some length in their article.

In the brackish water ponds of Java, where *Chanos chanos* (Forsk.) is cultivated, there are growths of *Zostera* and related genera, *Ruppia*, *Chondrocrispus* and other algæ which are not eaten by the fish. The fish are harvested by emptying the ponds and netting from a sump. I have seen the peasants at Soemenep in Madura digging the plants and algæ into the pon as green compost prior to refilling with water f the next crop of fish. In our small fish cultu station at Tapah in Malaya we are carrying this stage further, literally by composting the weed together with a considerable quantity of incident molluscs, worms, crustaceans and the eggs Amphibia. This compost is being permitted to r on the sides of the ponds and is ultimately returne to the ponds as manure. Critical analyses of th results will be published elsewhere.

In the Chinese-type pond, where the main speci cultivated are *Ctenopharyngodon idellus* (Cuv. an Val.), *Hypophthalmichthys molitrix* (Cuv. and Va and *Arristychthys nobilis* (Richardson), the 'weedin and composting take a different form. The flor population of the ponds is normally a rich phyt plankton. On this, a varied crustacean plankto fauna and small cyprinid fish fauna thrive, th perpetually reducing the essential productivity of t pond so far as the cultivated fish are concerned. T Chinese peasant realizes this, and in many ponds have seen them seine-netting their pond with a fin mesh net twice a week in order to catch the incidental organisms. These are then put into 'mash' which is fed to ducks and pigs living in pe on the side of the pond. The phosphates and nitrat are then returned to the pond by sweeping the pi and duck-droppings back. The Chinese peasant tes the nutrient salt concentration of the pond judging the density of the phytoplankton in th water, into which he will throw a broken piece white crockery, and by taking a mouthful of t water and gargling with it to ensure that the wat is 'sweet and fat'.

An extension of this principle of 'weeding' applied to the sea has come to light as the result preliminary studies on the catches of the sma mesh nets used by the fishermen in the Straits Malacca between peninsular Malaya and Sumatr Here we have a constantly moving body of wat which is almost totally surrounded by land on thr sides. There is a perpetual run-off from the ri volcanic mountains of Sumatra and the less ri mountains of Malaya. The bulk of the food fish Malaya are pelagic and pelagic feeders; but the fi population also contains a mass of small fish whi never grows to more than three inches in lengt They consist largely of Percomorphs. On the w coast of Malaya alone about twenty thousand to per annum of these small fish are taken by specia designed fishing gear with small meshes, and specifically fed to pigs and ducks or used as ag cultural fertilizer. Throughout the year, only 7 cent of the catch is the young of fish which wh adult are used as human food. As the result studies by this Department, it seems clear that taking of this mass of small fish from the sea p petually is a form of 'weeding' which permits th species which are of economic value as human fo the more readily to grow and proliferate. C sequently, under these conditions, a rational empl ment of small-meshed nets is encouraged, as it p motes proper conservation of our fish resources a plays an important part in the ultimate product of protein food.

REVERSIBILITY OF THE PROPAGATION REACTION IN POLYMERIZATION PROCESSES AND ITS MANIFESTATION IN THE PHENOMENON OF A 'CEILING TEMPERATURE'

By DR. F. S. DAINTON and K. J. IVIN
Department of Physical Chemistry, Cambridge

ALL addition polymerizations are exothermic and involve a decrease in entropy. The heat f reaction ($q = -\Delta H$) and the decrease in entropy $-\Delta S$) per mole of monomer polymerized really fer to the values of these quantities appropriate the *propagation* step, at the concentration of onomer ($= [m_1]$) prevailing in the system*. We ay write this reaction conventionally as

$$_p = A_p\, e^{-E_p/RT}, \quad m_1 + m_j{}^* \rightarrow m_{j+1}{}^* + q \text{ (k.cal.mole}^{-1}\text{)}, \quad (1)$$

which $m_j{}^*$ denotes an active species, either a radical an ion, containing j sub-units, m_1 denotes mono- er, k_p the rate constant, E_p the energy of activation nd A_p the frequency factor. From the principle microscopic reversibility, it can be shown that a everse reaction, which we shall call the *depoly- erization* reaction, also exists, namely:

$$_d = A_d\, e^{-E_d/RT}, \quad m_j{}^* \rightarrow m_{j-1}{}^* + m_1 - q. \quad (2)$$

his was first pointed out by Taylor and Tobolsky[1], nd later, Tobolsky and others[2] showed that at any emperature an equilibrium molecular weight distribu- ion exists which can be demonstrated for a solution f styrene in toluene at 100° C., and approached from oth high and low molecular weight sides by a supply f free radicals. More recently, Grassie and Melville[3] ave shown that under conditions in which the quilibrium is artificially displaced by continuous emoval of monomer, the depolymerization of poly- ethyl-methacrylate radicals will proceed to com- letion. In the course of a study of the copolymeriza- ion of olefines and sulphur dioxide[4] we have re- onsidered the effect of temperature on polymeriza- ion reactions in general and conclude that, as the mperature is increased, the rate should first rise xponentially, then pass through a maximum value nd finally fall to zero at a 'ceiling temperature' (T_c) efined by $T_c = \dfrac{\Delta H}{\Delta S}$, and which, under certain con- itions, should be realizable experimentally[5]. The ain features of the argument and conclusions are tlined below.

(*a*) *Kinetic Argument.* The propagation reaction (1) enerally has a small energy of activation but a large egative entropy of activation ($\Delta{}^{s}{}_{p}{}^{\ddagger}$). For example, amford and Dewar[6] have shown that for the poly- erization of styrene $E_p = 6{\cdot}5$ k.cal., $A_p = 1{\cdot}02 \times 10^6$ re mole^{-1} sec.$^{-1}$, that is, $\Delta S_p{}^{\ddagger} = -35$ cal.mole^{-1} eg.$^{-1}$. For reactions in the liquid phase for which $\Delta E^0 \simeq \Delta H^0$, we may write $E_d = E_p - \Delta H^0 = E_p + q$, but also A_d should be much larger than A_p, of the order of magnitude 10^{+13} sec.$^{-1}$ characteristic of unimolecular decomposition processes. Correspondingly, $\Delta S_d{}^{\ddagger} = \Delta S_p{}^{\ddagger} - \Delta S^0 \simeq 0$. Since heats of polymerization lie in the range 10–20 k.cal.mole^{-1}, k_d will increase with temperature much more rapidly than k_p and there may well be a temperature above which it is no longer justifiable to neglect k_d in comparison with $k_p[m_1]$. The rate of reaction should then be written

$$-\frac{d[m_1]}{dt} = \Sigma[m_j{}^*]\,\{A_p[m_1]\, e^{-E_p/RT} - A_d\, e^{-(E_p+q)/RT}\}. \quad (3)$$

When steady state conditions are attained the concentration of growing ends, that is, $\Sigma[m_j{}^*]$, will be a function of the initiation and termination rates only. For photochemically initiated chains this term may decrease with temperature, whereas for thermally initiated chains it will always increase due to the considerable energy of activation of the initiation reaction. The form of the terms in brackets is depicted in Fig. 1 and the forms of the log rate *vs.* $1/T$ curve for the two cases of photochemical and thermal initiation will therefore take the form shown in Fig. 2. There is thus a 'ceiling temperature'[7], T_c, characteristic of every reaction, and above which it will not proceed. From equation (3)

$$T_c = \frac{q}{2{\cdot}303\, R \log_{10}\left(\dfrac{A_d}{A_p[m_1]}\right)} = \frac{-\Delta H}{-2{\cdot}303\, R\left\{\log_{10}\dfrac{A_p}{A_d} + \log_{10}[m_1]\right\}}, \quad (4)$$

and therefore the ceiling temperature (1) is proportional to the heat of polymerization, (2) increases with the monomer concentration, (3) is independent

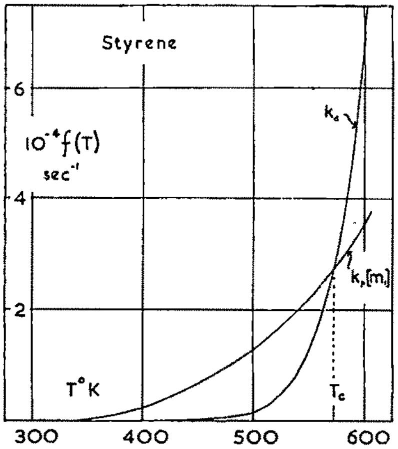

Fig. 1. Variation with temperature (T) of the propagation ($k_p[m_1]$) and depolymerization (k_d) velocities in liquid styrene. Data: $A_p = 1{\cdot}02 \times 10^6$, $E_p = 6{\cdot}5$ k.cal., $[m_1] = 8\,M$, $E_d = (6{\cdot}5 + 16{\cdot}1)$ k.cal., A_d assumed $= 10^{13}$. All in litre-mole-sec. units

of the mechanism of the initiation and termination reactions, provided the same type of product is formed, that is, A_d/A_p constant, and (4) is the temperature at which the specific viscosity of a solution of the final polymer should have fallen to zero.

---

* The justification for this statement is as follows. Let the average mber of monomer units (m_1) per polymer molecule (m_r) be r, and e increment in any thermodynamic function χ per molecule of mono- er added in the propagation step be $\delta\chi_p$, per molecule of monomer tivated ($m_1 \rightarrow m_1{}^*$) in the initiation process be $\delta\chi_i$, and per polymer ain terminated ($m_r{}^* \rightarrow m_r$) be $\delta\chi_t$. Assuming $\delta\chi_p$ to be independent chain-length, the value of $\Delta\chi$, the increment in χ for 1 mole of mono- er polymerized ($Nm_1 \rightarrow \frac{N}{r}\, m_r$, where $N = 6{\cdot}023 \times 10^{23}$) will be ven by $\Delta\chi = \frac{N}{r}(r-1)\,\delta\chi_p + \frac{N}{r}\,\delta\chi_i + \frac{N}{r}\,\delta\chi_t$. For long chains, $\simeq r - 1$, the last two terms may be neglected and therefore $\chi = N\delta\chi_p$. Since $\Delta\chi$ is determined solely by the initial (monomeric) d final (polymeric) states of the system, the interesting corollary that $\delta\chi_p$ is independent of the reaction mechanism, that is, $\Delta S =$ $/A_d$, and q should have the same values whether mj^* is a radical, or is merely polarized.

(*b*) *Thermodynamic Argument.* At the ceiling temperature the reaction-rate is zero and the system is in thermodynamic equilibrium. Writing $\Delta G = 0 = \Delta H - T_c \Delta S$

$$T_c = \frac{\Delta H}{\Delta S}, \qquad (5)$$

where ΔH and ΔS refer to the change in the thermodynamic functions for the reaction carried out at the prevailing monomer concentration. If the standard state refers to unit concentration and the monomer behaves ideally, $\Delta S = \Delta S^0 + R \log [m_1]$, whence

$$T_c = \frac{\Delta H}{\Delta S^0 + 2{\cdot}3R \log_{10} [m_1]}. \qquad (6)$$

Equation (6) emphasizes that T_c is characteristic of the monomer-polymer relationship only and is quite independent of reaction mechanisms, that is, whether free radicals or ions or polarized double bonds are the active centres.

The link between equations (4) and (6) is the usual one between the kinetic and thermodynamic approach to problems of reaction kinetics. On the transition state theory[8] a frequency factor $A = e^2 \frac{kT}{h} e^{\Delta S^{\ddagger}/R}$, and making appropriate substitution $\Delta S^0 = \Delta S_p{}^{\ddagger} - \Delta S_d{}^{\ddagger} = -R \log\left(\frac{A_d}{A_p}\right)$ and equation (6) becomes

$$T_c = \frac{-\Delta H}{-\Delta S^0 - R \log [m_1]} = \frac{q}{2{\cdot}3\, R \log_{10}\left(\frac{A_d}{A_p [m_1]}\right)}. \qquad (7)$$

Measurements of ceiling temperatures and heats of polymerization thus have a dual importance thermodynamically. First, they permit actual entropy changes in polymerization reactions to be determined, and secondly, if q is known as $f(m_1)$, the variation of T_c with $[m_1]$ can be used to examine any departures from ideal behaviour of monomer solutions.

(*c*) *Experimental Verification.* Existing data concerning the polymerization of single vinyl compounds do not provide a rigid test of these conclusions. There are many reasons why this should be the case. The ceiling temperature may be so high that in this temperature region the monomer may be cracked or the thermal initiation be so rapid that the photochemical reaction cannot be adequately studied separately. Nevertheless it is interesting that, taking $A_p = 1{\cdot}02 \times 10^6$ litre mole^{-1} sec.$^{-1}$, $E_p = 6{\cdot}5$[6], $A_d = 10^{13}$ sec.$^{-1}$ and $q = 16{\cdot}1$ k.cal.[9], the ceiling temperature for liquid styrene ($[m_1] = 8$ mole litre^{-1}) deduced from equation (4) is 299° C. We have found that liquid styrene sealed in capillary tubes polymerizes rapidly at 300° C., but a solution of polystyrene in the monomer depolymerizes readily at 330°. Unfortunately the absolute rates at these temperatures are too large to permit accurate verification of the existence of a maximum rate. Further experiments are projected with molar solutions of styrene for which T_c may be in the region of 220°–230° C.

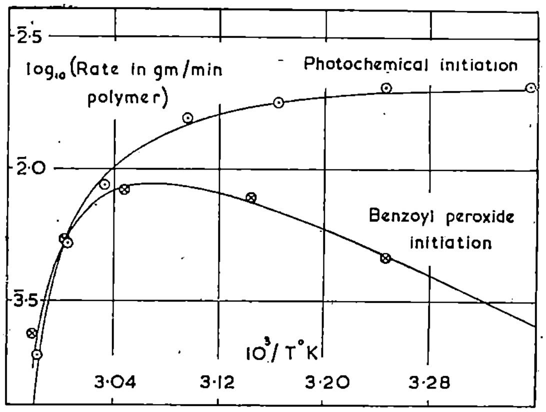

Fig. 2. Temperature dependence of the rate of polysulphone formation in mixtures containing 1 mole of 1-butene in 10 moles sulphur dioxide. ⊙ and ⊕ denote experimental observation for photochemical and peroxide initiation. Full lines represent theoretical variation .

The same principles apply to copolymerizatio reactions. In the special case of the copolymerization of sulphur dioxide and olefines[4]; points (3) an (4) in section (*a*) have been verified, and Fig. 2 show data we have obtained for 1-butene–sulphur dioxid mixtures in which the mol fraction of the olefine i 0·091. The three ceiling temperatures observed fo the photochemical reaction, the benzoyl peroxid catalysed reaction, and the silver nitrate catalyse reaction all lie in the range 62–64° C. Moreover the values obtained by the short extrapolation of th $\frac{\eta_{sp}}{c}$ *vs.* T curves are also within these limits. Suc constancy of T_c is the more striking in view of th mixed termination mechanism which is operativ and also in that the dead polymer is not reactivate in the reaction. In fact, at 77° C., 1-butene polysulphone, either alone or in the presence of radicals does not revert to reactants. Some support for thes ideas is also afforded by the work of Snow and Frey[7] who observed that the ceiling temperature varied wit the olefine used. The order of increasing ceiling temperatures (isobutene, 4° C.; 2-butene, 43° C. 1-butene, 63° C.; propylene, 87° C.) is the order o decreasing steric hindrance in the polymerizatio reaction and therefore also the probable order o increasing heat of reaction. Accurate measurement of the heats of formation of polysulphones are no in progress (see note at end, p. 707).

The detailed kinetics of the 1-butene reaction cannot be discussed here. It must suffice to say that radical with a butene end can only add sulphu dioxide and vice versa. If the corresponding frequency factors are $A_p{}^b$ and $A_p{}^s$, and for depolymerization are $A_d{}^b$ and $A_d{}^s$, it can easily be show that

$$T_c = q/2{\cdot}303 \log_{10} \left\{\frac{A_d{}^b\, A_d{}^s}{A_p{}^b\, [\mathrm{SO_2}]\, A_p{}^s\, [\mathrm{Bu}]}\right\}. \qquad (8$$

q was found from calorimetric measurements to b 22 k.cal., and hence $\Delta S = -66$ cal. deg.$^{-1}$ per mo SO$_2$ *and* butene polymerized. The full lines in Fig. corresponding to $T_c = 62{\cdot}7°$ C., imply that $\frac{A_p{}^b\, A_p{}^s}{A_d{}^b\, A_d{}^s} =$ $2{\cdot}77 \times 10^{-15}$ litres^{+2} mole^{-2}; that is, $\Delta S^0 = -64{\cdot}9$ cal. deg.$^{-1}$ per mole SO$_2$ + butene. If we assum $A_d{}^s = A_d{}^b = 10^{13}$ sec.$^{-1}$, then $A_p{}^s A_p{}^b = 3 \times 10$ litre^2 mole^{-2} sec.$^{-2}$. This latter value is not unreaso ble for the product of the two (probably unequal) propagation frequency factors and should be compared with the value of 10^{12} litre^2 mole^{-2} sec.$^{-2}$ for the product of two successive (equal) propagation requency factors in styrene.

We wish to express our thanks to the Royal Society and the Chemical Society for grants made in aid of this investigation.

Note added in proof, October 4, 1948.—We have now obtained direct experimental verification of oints (1) and (2) in section (*a*). Thus, in 1-butene polysulphone formation T_c depends on [Bu][SO$_2$] xactly as predicted in equation (8); the heat of eaction for 1-butene is 22·0 ± 0·7 and for 2-butene s 20·5 ± 1·7 k.cal., indicating that the lower T_c for the latter is due to the smaller q, as suggested. (We are indebted to Mr. D. G. L. James for help with he adiabatic calorimetry.)

UNIVERSITY OF BERGEN

THE University of Bergen was opened on August 30 by the Crown Prince of Norway. At the same time three hundred new students were matriculated and welcomed.

The University of Bergen starts with three faculties, namely, mathematics and natural sciences, humanities, and medicine. It will be further built up in accordance with plans prepared by a committee for the University, which forwarded its proposals to the executive body so long ago as 1939.

The Faculty of Mathematics and Natural Sciences and the Faculty of the Humanities are being developed from the old and well-known institution, the Bergen Museum, whereas the Faculty of Medicine based on the municipal hospitals and the State gynæcological hospital in Bergen. From August 30, 1948, these different institutes are associated together a common scientific institution, the University of Bergen.

The Bergen Museum already had ten different departments, eight of which now belong to the Faculty of Mathematics and Natural Sciences. These departments are the following: (1) Zoology, professorship for the moment vacant. (2) Mineralogy and geology, Prof. N.-H. Kolderup. (3) Systematic botany, with a botanic garden, Prof. K. Fægri. The collections belonging to these departments are kept in the old main building of the former Bergen Museum. A biological station built in 1927 at Herdla the neighbourhood of Bergen is associated with e Department of Zoology. (4) General botany, Prof. O. Hagem. (5) Chemistry (and biochemistry), Prof. T. Gaarder. In the Geophysical Institute, which was built in 1928 in the neighbourhood of the main building of the Bergen Museum, three different departments have laboratories, offices and workshops: (6) Oceanography, Prof. H. Mosby. (7) Meteorology, Prof. C.-L. Godske. (8) Cosmic physics with terrestrial magnetism, Prof. B. Trumpy. According to the plans of the committee of 1939, the Department of Cosmic Physics will take over the duties of a Department of Physics at the new University. Two new institutes are now being built in the neighbourhood of the Geophysical Institute. According to present plans, these buildings will be completed and come into use during the session 1949–50. They will provide laboratories, offices and workshops for the Departments of Chemistry, General Botany and Physics.

It may be mentioned that on the initiative of O. Dahl and B. Trumpy a laboratory building for nuclear physics has just been completed to plans drawn up by them. In the near future it is hoped to begin work on the installation of a 1·8-MeV. van de Graaff generator and a 50-MeV. betatron in this building. The Institute of Nuclear Physics, which has been built by the aid of funds not appearing in the University budget, will nevertheless in the future be the property of the University.

Funds for a professorship in mathematics have been granted from the beginning of the year 1948–49; and an appointment will be made in the near future.

At the present time, the Faculty of the Humanities consists of two departments only. The corresponding departments of the former Bergen Museum, namely, the Department of Archæology (Prof. Johs. Böe), with valuable collections relating to the old history of Norway in the new Museum (1927), and the Department of Norwegian Philology (Prof. O. Skulerud), have been taken over unchanged by the University.

A professorship in philosophy is vacant; a new professor will be appointed in the near future. For the moment, a number of temporarily appointed instructors are lecturing on different subjects belonging to the Faculty of the Humanities, as, for example, philosophy, Latin, general philology, phonetics, and different living languages such as Norwegian, English, French and German. It is to be hoped that the Norwegian Government will encourage the rapid development of the new University by establishing the necessary new teaching posts in the Faculty of Mathematics and Natural Sciences, as well as in the Faculty of the Humanities.

As mentioned before, the Faculty of Medicine is based upon the municipal hospital in Bergen—Haukeland Sykehus—and the State gynæcological hospital in Bergen. The instruction of medical students started at these hospitals in 1946 as a subsection of the Faculty of Medicine of the University of Oslo. From August 30, 1948, the section in Bergen has been working as an independent faculty at the new University.

Medical studies in Bergen will for the present be purely clinical. Instruction in the pre-clinical subjects will temporarily be given only at the University of Oslo. Indeed, the institutes of anatomy and physiology in Oslo have a considerably greater capacity for instruction than the clinical departments; consequently the extension of the possibilities of clinical studies by the foundation of a Faculty of Medicine at Bergen had become very desirable.

The departments of the Faculty of Medicine at the University of Bergen are as follow: gynæcology and obstetrics (Prof. J. Lövset); pathology (Prof. E. Waaler); surgery (Prof. H. Gade); clinical medicine (Prof. H. Rasmussen); dermato-venerology

(Prof. I. Rokstad); psychiatry (Prof. F. Rud); bacteriology (Prof. Th. M. Vogelsang); roentgenology (Prof. S. N. Bakke). Instruction is also given in pharmacology, orthopædics and hygiene.

On July 9, 1948, an act creating the University of Bergen was sanctioned by the King's order in council. It was decided that the University, during a transition period, should be governed by a temporary senate, consisting of: Prof. B. Trumpy, Rector of the University; Prof. E. Waaler, dean of the Faculty of Medicine; Prof. N.-H. Kolderup, dean of the Faculty of Mathematics and Natural Sciences; and Prof. Johs. Böe, dean of the Faculty of the Humanities.

B. TRUMPY

RULES OF ZOOLOGICAL NOMENCLATURE

DURING the thirteenth International Congress of Zoology, which closed in Paris on July 27, the International Commission on Zoological Nomenclature, holding its first meeting since the close of the Second World War, put forward a comprehensive programme for the reform and development of zoological nomenclature. All the thirteen meetings held by the Commission were open to all the members of the Congress, who were thus enabled to take an active part in the discussion of the proposals put forward by the Commission. As a result it was possible not only to obtain decisions on a much larger number of questions than would otherwise have been practicable, but also to ascertain much more readily the needs and general wishes of zoologists. The scheme finally adopted was approved unanimously by the Section on Nomenclature and, on the recommendation of the Section, by the Congress itself at its final plenary session.

Prior to the opening of the Paris meeting, extensive discussions had been undertaken by the Commission with leading scientific institutions and individual specialists in different parts of the world, with the double purpose of drawing up a scheme which would ensure for the Commission the highest possible representative and international character, and would secure that at the Paris meeting all practicable measures should be taken to improve and develop the *Règles Internationales de la Nomenclature Zoologique.*

Measures taken to secure a fully representative and international character for the Commission. Hitherto the International Commission has had a fixed membership of eighteen commissioners, but in future there will be no fixed upper limit to its membership, though the number of eighteen will be retained as the minimum membership. Under the new system it will be possible therefore for the zoologists of any country in which any considerable body of zoological work is being carried out to have direct representation on the Commission. The change now made will make it possible also for the Commission to call to its membership leading specialists in particular fields irrespective of country. Machinery is at the same time provided for consultation with the leading scientific institutions in any country in regard to the selection of its representative on the Commission.

Measures taken to reform the procedure of the Commission. The extensive series of changes in the procedure of the Commission are designed to secure that in future the Commission shall be able to reach decisions much more rapidly than has been possible in the past. The most important single reform is the abandonment of the *Liberum Veto* under which either 'during a meeting or when business is conducted by correspondence a single member of the Commission could prevent any decision being taken by the Commission either in the formulation of recommendations for the improvement of the *Règles*, or in the use of the plenary powers given to the Commission to conserve zoological names which are in common use but are technically defective. Other reforms agreed upon are designed to eliminate all unnecessary delay in the consideration of nomenclatorial problems submitted to the Commission by specialists. It is hoped that under this revised procedure it will normally be possible for the Commission to promulgate its decision on any question put to it within eighteen months of the date of the application.

Reform and development of the Règles. At the opening of the Paris meeting, the *Règles* in force were substantially the same as those which had been adopted at the Congress of Zoology held in Berlin in 1901. The object of the reforms now agreed upon is to clarify the text of the *Règles*, which experience has shown to be in many cases obscure, to make the *Règles* more comprehensive by introducing provisions on questions not hitherto included in that instrument and, where necessary, to introduce changes into them in order to bring their provisions into harmony with general wishes. By these means it is hoped to retain everything that experience has shown to be valuable, to eliminate all those passages which have been found to be unsatisfactory, and to meet the needs of zoologists by the introduction of provisions on matters which have hitherto not been subject to international regulation.

Codification of the international law on zoological nomenclature. A large part of existing international law on zoological nomenclature is to be found not in the *Règles* themselves but in "Opinions" rendered by the International Commission acting in the judicial capacity entrusted to it by the International Zoological Congress at Boston in 1907. The complex body of case law which has thus grown up over the last forty years has made the task of zoologists extremely difficult. A wide welcome will therefore be given to the decision now taken in Paris to codify the law by incorporating in the *Règles* themselves the decisions hitherto embodied only in the "Opinions" of the Commission. Another reform of great practical value is afforded by the decision to record in special schedules attached to the *Règles* the decisions taken by the Commission in particular cases. With regard to decisions to be taken by the Commission in the future, these will be of either of two kinds: (1) decisions on matters of principle which will be issued as *Declarations* and take the form of proposed amendments to be incorporated in the *Règles* after approval by the next Congress; and (2) decisions on individual cases which will be issued as *Opinions* and which after the next Congress will be inserted in the appropriate schedule to the *Règles.* Thus the Commission intends to ensure that in future a zoologist will be able to find the whole body of international law in regard to zoological nomenclature within the covers of a single volume.

Preparation and promulgation of the revised substantive French text of the Règles. Recognizing the highly technical problems inevitably involved in the preparation of a substantive text giving effect to the numerous changes which have now been agreed upon e Congress, on the advice of the Commission, cided that this task shall be entrusted to jurists fore whom the decisions of the Congress will be id; the text prepared by the jurists will be sub- itted to the members of the Commission for final proval; the task of considering any drafting points hich may emerge from the foregoing consultation s been entrusted to a special Committee of three, nsisting of: Mr. Francis Hemming (United King- m), secretary to the Commission; Dr. van Straelen elgium) and Prof. Robert E. Usinger (United ates).

Contrasted provisions for dealing with old names d new names. The *Règles* in their amended form ll come into operation immediately they are omulgated. In the meanwhile, arrangements are ing made for the publication as soon as possible of e *Procès Verbaux* of the Commission during its aris meeting in the Commission's *Bulletin of Zoo- gical Nomenclature*. In general, it will be found that, order to ward against the risks involved in retro- tive legislation, the provisions relating to names ready published are simpler and less rigorous than ose to be applied to names to be published in the ture. From now onwards workers giving new ames will have at their disposal rules which are mple, clear, and easy to operate. The position as gards names already published—and especially mes published before the introduction of the *Règles* fty years ago—will necessarily be rather more mplicated. It is hoped, however, that, as regards neric names, these difficulties will be largely over- me by a rapid and substantial extension of the Official List of Generic Names in Zoology", for nder the arrangements now agreed upon, a name ce placed on this List is not to be changed for any rely nomenclatorial (as contrasted with taxonomic) ason without the prior approval of the International mmission. A similar provision has been made in gard to the trivial names of species, and for these so there has now been established an "Official List" names which are not in future to be changed for rely nomenclatorial reasons without the prior proval of the Commission. The establishment of ese two "Official Lists" makes it possible for ecialists in any group to concert proposals for bmission to the Commission for the insertion on ese "Official Lists" of the names of the genera and ecies in their group and thereby to protect those mes from changes for any reason other than xonomic considerations.

Value of preliminary studies on particular problems. e work of the present meetings was greatly assisted two important matters by the decision taken at the evious Congress (held at Lisbon in 1935) that before e present meeting a detailed study should be made two important questions of nomenclature which d been a cause of difficulty for many years. In ch case the reports so submitted to the Paris eetings provided the basis for an agreed settlement. e first of these reports was concerned with the eaning of the expression "nomenclature Binaire" as ed in the *Règles*: in this case the Commission and e Congress have agreed to substitute the expression omenclature binominale" for the expression referred above, subject to the incorporation of safeguards generic names published by "binary" though t binominal authors. The second of these reports s concerned with the problem of the nomenclature forms of less than subspecific rank, a matter on ich no provision had hitherto been made in the *Règles*. In this case also the report submitted provided the basis for an agreed settlement. The Commission and the Congress have been so much impressed by the value of this procedure that they have now agreed that similar reports should be prepared for consideration at the next Congress in regard to other difficult problems, including (1) the treatment of family names; (2) the nomenclature of orders and higher groups; (3) the rules which should govern the emendation of names and (4) the problems presented by the demand for the recognition of 'neotypes'.

Settlement of outstanding individual cases. Owing to the War and other causes, the Commission at the beginning of the Paris meeting were confronted with heavy arrears of work in connexion with individual applications submitted by specialists in different parts of the world. During the recent meeting decisions were taken on almost all these cases, and these decisions will be promulgated in the near future.

The outlook. The effect of the reforms in the *Règles* instituted during the Paris meeting will be to provide zoologists with a system of law which will be much easier to operate and will ensure stability and uniformity in the nomenclature. At the same time the reforms in the constitution of the Commission and its procedure will assure to zoologists a central authority in regard to all matters relating to zoological nomenclature far more representative and international than ever before and, as such, capable of providing a service more extensive and of much greater value than has been possible at any previous time.

FRANCIS HEMMING
(Secretary to the International
Commission on Zoological Nomenclature)

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, November 1

UNIVERSITY OF LONDON (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Prof. K. Linderstrøm-Lang: "Enzymatic Breakdown of Proteins, II".*

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 5.30 p.m.—Mrs. F. N. Betts: "Innermost Assam" (Kodachrome films with commentary).

SOCIETY OF ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. C. B. Brown: "Soil Mechanics and the Practical Engineer".

Tuesday, November 2

UNIVERSITY COLLEGE, LONDON (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. J. Z. Young, F.R.S.: "Process of Learning in Octopus".*

CHADWICK PUBLIC LECTURE (in the Sir Edward Meyerstein Lecture Theatre, Westminster Hospital Medical School, 17 Horseferry Road, London, S.W.1), at 2.30 p.m.—Mr. Wyndham E. B. Lloyd: "The Prevention of Tuberculosis, with special reference to Environment".*

ROYAL ANTHROPOLOGICAL INSTITUTE (joint meeting with the INTERNATIONAL AFRICAN INSTITUTE, at 21 Bedford Square, London, W.C.1), at 5 p.m.—Mrs. G. M. Culwick: "An Investigation into the Diet of the Zande of the Sudan".

ROYAL STATISTICAL SOCIETY, RESEARCH SECTION (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 5.15 p.m.—Discussion on "Some Statistical Problems Arising in Genetics" (to be opened by Prof. J. B. S. Haldane, F.R.S.).

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting of the MEASUREMENTS AND RADIO SECTIONS, at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Prof. F. C. Williams and Mr. T. Kilburn: "A Storage System for use with Binary Digital Computing Machines".

SIR HALLEY STEWART TRUST LECTURE (at the Memorial Hall, Farringdon Street, London, E.C.4), at 6 p.m.—Prof. P. M. S. Blackett, F.R.S.: "The Atomic Age—The Military Consequences of Atomic Energy".*

INSTITUTE OF METALS, SOUTH WALES SECTION (at University College, Singleton Park, Swansea), at 6.30 p.m.—Mr. Ivor Jenkins: "Controlled Atmospheres in Non-Ferrous Metallurgy".

Textile Institute, Midlands Section (joint meeting with the Derby Textile Society, at the Midland Hotel Derby), at 6.45 p.m.—Mr. H. Halkyard: "Processing of Acetate Rayon".

Chemical Society, Eire Branch (at University College, Dublin).—Prof. H. J. Emeléus F.R.S.: "The Production and Uses of Radioactive Tracers". (To be repeated on Thursday, November 4, at University College, Cork; on Monday, November 8, at University College, Galway; and on Thursday, November 18, at University College, Hull.)

Wednesday, November 3

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. G. W. A. Dummer: "Aids to Training—The Design of Radar Synthetic Training Devices for the R.A.F.".

Manchester Metallurgical Society (joint meeting with the Local Section of the Institute of Metals, at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Dr. N. P. Allen: "Recent Developments at the National Physical Laboratory".

Society of Public Analysts and other Analytical Chemists (at Gas Industry House, 1 Grosvenor Place, London, S.W.1), at 7 p.m.—Scientific Papers.

Thursday, November 4

Physical Society, Acoustics Group (at the Royal Society of Arts, 6 John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Discussion on "Concert Hall Acoustics" (to be opened by Mr. Hope Bagenal).

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Miss Audrey U. Smith: "Some Antigenic Properties of Mammalian Spermatoza"; Mr. H. McIlwain: "Metabolic Charges which form the basis of a Microbiological Assay of Nicotinic Acid".

Chemical Society, Sheffield Branch (joint meeting with the University Chemical Society, in the Chemistry Department Lecture Theatre, The University, Sheffield), at 5.30 p.m.—Prof. W. T. Astbury, F.R.S.: "The Electron Microscope and some Recent Discoveries with it in the Field of Macromolecules".

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. F. J. Erroll, M.P., and the Lord Forrester: "Some Projects favourable to Direct-Current Transmission, and the Role of the British Electrical Industry in relation Thereto".

King's College (in the Department of Civil, Mechanical and Chemical Engineering, Strand, London, W.C.2), at 5.30 p.m.—Prof. S. J. Davies: "Heat Pumps and Thermal Compressors".* (Further Lectures on November 11, 18 and 25.)

Royal Institute of Chemistry (at the Technical College, Brighton), at 6 p.m.—Dr. K. G. A. Pankhurst: "Protein-Detergent Complexes and some of their Uses in Industry".

Leeds Metallurgical Society (in the Chemistry Department, The University, Leeds), at 7 p.m.—Dr. R. Genders: "War-time Metallurgical Developments in Great Britain".

Textile Institute Yorkshire Section (at the Technical College, Keighley), at 7 p.m.—Mr. R. J. Steele: "The Mystery of Colour".

Friday, November 5

Association of Applied Biologists (in the Botany Lecture Theatre, Imperial College of Science and Technology, London, S.W.7), at 2 p.m.—"The Insecticidal Properties of Certain Organo-Phosphorus Compounds".

Physical Society (in the large Physics Theatre, Imperial College of Science, Imperial Institute Road, London, S.W.7), at 5 p.m.—Extraordinary General Meeting; at 5.10 p.m.—Scientific Papers.

University College, London (in the Anatomy Theatre, Gower Street, London, W.C.1), at 5 p.m.—Prof. G. Levi: "Relations of Interdependency between the various parts of the Nervous System in the Embryo and in the Adult".* (The Lecture will be delivered in French.)

Society of Chemical Industry, Manchester Section (joint meeting with the Local Sections of the Chemical Society and the Royal Institute of Chemistry, at the Engineers' Club, Albert Square, Manchester), at 6.45 p.m.—Prof. J. Read, F.R.S.: "Studies in Australian Plant Chemistry".

Paper Makers' Association, Technical Section, Northern Division (at the Engineers' Club, Albert Square, Manchester), at 7 p.m.—Mr. G. G. Taylor: "Colour Measurement".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. C. G. Butler: "Bee Behaviour".

Saturday, November 6

Royal Institute of Chemistry (joint meeting with the Institute of Physics and the Institute of Metallurgists, at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 10 a.m.—"The Origins and Prevention of Laboratory Accidents".

Geologists' Association (at Chelsea Polytechnic, Manresa Road, London, S.W.3), at 2.30 p.m.—Annual Re-union.

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 2.30 p.m.—Mrs. F. N. Betts: "The Zemi Nagas—the Life of an Assam Hill Tribe" (with film).*

Institution of Chemical Engineers, North-Western Section (joint meeting with the Chemical Engineering Group of the Society of Chemical Industry, at the College of Technology, Manchester), at 3 p.m.—Mr. J. Leyland: "The Cooling of Circulating Water for Coolers and Condensers".

APPOINTMENTS VACANT

Applications are invited for the following appointments on before the dates mentioned:

Head (male) of the Poultry Department, and Teacher (fema in Dairying, for the Ulster Dairy School (for girls), Cookstown, C Tyrone—The Establishment Officer, Ministry of Agriculture, Stormon Belfast (November 6).

Educational Psychologist by Middlesex County Council Educ tion Committee for Ealing—The Borough Education Officer, Castlebar Road, London, W.5, quoting F.22.T (November 8).

Assistant Lecturer in Phonetics—The Registrar, The Un ersity, Leeds 2 (November 9).

Civilian Lecturers (2) in the Department of Physics a Electrical Engineering of the Royal Naval College, Greenwich—T Secretary, Admiralty (C.E. Branch), Whitehall, London, S.W (November 12).

Principal Scientific Officer or Senior Scientific Offic (Mineralogist), and a Principal Scientific Officer (with Fi or Second Class Honours degree in chemical engineering, or in engine ing with corporate membership of the I.C.E., or in science or math matics with post-graduate study in chemical engineering), at t Ministry of Supply Research Establishment, Harwell—The Secreta Civil Service Commission, Scientific Branch, 27 Grosvenor Squa London, W.1, quoting No. 2304 (November 12).

Lecturer in Applied Mathematics—The Registrar, Univers College, Southampton (November 13).

Alan Johnston, Lawrence and Moseley Research Fellows —The Assistant Secretary, Royal Society, Burlington Hou London, W.1 (November 15).

Lectureship in Chemistry, with special qualifications in physi chemistry—The Secretary, The University, Aberdeen (November 1

Lectureship in Physical Chemistry—The Secretary, The Un ersity, Aberdeen (November 15).

Assistant Lecturer in Physics, and an Assistant Lectur in Geography—The Registrar, The University, Manchester (November 19).

Assistant Lecturer in Geography—The Registrar, The Un ersity, Nottingham (November 19).

Lecturer (Grade III) in Chemistry—The Registrar, Queen Ma College, Mile End Road, London, E.1 (November 22).

Laboratory Technician with knowledge of simple biochemi procedures and also of electrical apparatus—The Professor of Surge Queen Elizabeth Hospital, Birmingham 15 (November 30).

Imperial Chemical Industries Fellowship tenable in the Durh Division or the Newcastle Division of the University of Durham The Registrar, University Office, 46 North Bailey, Durham (Nove ber 30).

Professor of Veterinary Science at Makerere College, Kampa Uganda—The Secretary, Inter-University Council for Higher Edu tion in the Colonies, 8 Park Street, London, W.1 (November 30).

Lecturers (2) in Physics at the Natal University College (o lecturer in the Department of Physics at Pietermaritzburg, and o lecturer in the Department of Experimental Physics at Durban) The Secretary, Association of Universities of the British Commo wealth, 32 Woburn Square, London, W.C.1 (December 1).

Lectureship in Economic Statistics in the Faculty of Econom at the University, Sydney—The Secretary, Association of Universit of the British Commonwealth, 32 Woburn Square, London, W. (December 31).

Assistant Biochemist—The Medical Superintendent, Dud Road Hospital, Birmingham 18.

Scientific Assistant—The Director, Commonwealth Bureau Horticulture and Plantation Crops, East Malling, Maidstone, Kent.

Senior Assistant in Dyeing and Textile Chemistry at t Technical College—The Director of Education, Town Hall, Bradfo

Senior Lecturer in Chemistry—The Clerk to the Governo Chelsea Polytechnic, Manresa Road, London, S.W.3.

Assistant Experimental Officer in the Bacteriologic Department, to assist with investigations into mastitis in dairy co —The Secretary, National Institute for Research in Dairying, Sh field, Berks.

Lecturer in Physical and Inorganic Chemistry at Brigh Technical College—The Education Officer, 54 Old Steine, Bright

Laboratory Steward in the Science Department of the C stantine Technical College—The Director of Education, Middlesbrou

Technician with special experience in hæmatology, a Gene Laboratory Technician, and a Histological Technician, for Department of Pathology and Bacteriology—The Secretary, We National School of Medicine, 34 Newport Road, Cardiff.

Chair of Geology—The Registrar, The University, Nottingham

SCIENTIFIC RESEARCH AND MAN-POWER

THE address which Mr. Herbert Morrison, the Lord President of the Council, delivered to the Conference of Industrial Research Associations on October 15 (see *Nature*, October 23, p. 645) should be studied carefully by all who are concerned with the conduct of scientific research and, in this time of stringently limited man-power, with the most effective distribution of the available scientific man-power between industry, the universities and the Government services in Britain. The development of the industrial research associations, with which the Lord President was ostensibly concerned, cannot wisely be considered apart from the general research effort of the country. As the recent report of the Advisory Council on Scientific Policy indicated, approximately ten per cent of the qualified scientific workers engaged in Great Britain's research effort are already employed by the research associations. At the present time, any appreciable increase in their numbers must be at the expense of those employed in research in industry, in the universities or in other Government departments.

Mr. Morrison, in referring to the Government policy of encouraging the establishment of research associations and the assurance given three years ago that Government support would not be withdrawn after an initial stage, said that the Government had been very much impressed by the results being obtained by some of the research associations. Last year, their total expenditure was close on £2 millions, as against £470,000 in 1938, and the total estimated for next year is £2·5 millions. Even allowing for the general rise in costs, the effort has more than doubled, and there are now thirty-eight research associations as against twenty-one in 1938 ; while the formation of others is expected in the near future. He hoped that the Conference would lead to even bigger developments.

Through all the examples of the work of the research associations which Mr. Morrison cited as having particularly impressed the Government runs the thread of increased productivity, or the increase of industrial efficiency by the saving of fuel and of labour. The Lord President seems to regard the research associations primarily as valuable contributors to the increased industrial productivity by which alone Great Britain can hold its place in competitive world industry. Further, his speech indicates approval for greater encouragement of the study of man in relation to the machines he has to operate—a matter in which, as Sir Henry Tizard pointed out in his presidential address at Brighton to the British Association, industry has lagged far behind the Services. It might, indeed, be inferred from his speech and from the increased attention being given by the research associations to what is known as 'operational research', as judged by examples recently quoted, that an increasing proportion of their effort will be directed to the study of the human aspects of production and economic and sociological problems, as distinct from those physical problems to which their original effort was almost exclusively devoted.

It is not disputed that the particular technique developed in war-time under the name of 'operational research' and long since employed in progressive industry in its technical service to customers may have large potentialities. Both the need and the opportunity for such methods might possibly diminish, however, if we could secure the more effective utilization by industry—and by the State—of existing knowledge. Mr. Morrison frankly recognized that a large part of the problem of increasing productivity and industrial efficiency lies in securing the utilization of the results of past research as well as of that at present proceeding, and he indicated the readiness of the Government to use whatever resources are at its disposal to see that proved processes and equipment developed by the research associations should not be left unutilized.

Nevertheless, although the Lord President stressed the importance of those engaged in research having full opportunity to know what are the problems of industry, and above all, the needs of users and consumers of industrial products—and, indeed, asked whether the opportunities in the research association movement for co-operation between all engaged in industry are being fully taken—he did not stay to discuss the fundamental question whether that was or was not due to any inherent defect in the research association idea itself. He did inquire whether there is enough in industry of the approach and interchange which characterized the development of equipment for the Armed Forces, and he also asked whether there are enough scientific workers employed in industry helping to get the best of the scientific results which are already available. He also dwelt at some length on the importance of scientific interpreters and liaison officers, and of encouraging, in every way possible, contacts and exchange of visits between scientific men and industry.

There is, indeed, a large field for co-operative effort where the research association, as Mr. Morrison indicated, may pay handsome dividends in terms of productivity and the saving of materials and labour. It is by no means established, however, that the research associations can compare with the research departments of industrial firms in the development of those new products and processes which place British industry ahead and not just abreast of its rivals in the world markets, and which, as Sir Henry Tizard reminded us, are the product of the work of very few men.

What needs to be considered much more closely is how best that spirit of enterprise and inventiveness can be fostered. Mr. Morrison touched on many important factors and indicated some of the means by which industry in Great Britain could recover some of the ground lost in the development stage to such countries as the United States. He said little, however, to show that he appreciated the importance of the really fundamental research in which Britain excels, and on which in the long run industrial advance is based.

Some of that work is being carried out by th research associations, and some of it in the laboratories of leading industrial firms. By far the greate part of it, however, is proceeding in the universit laboratories; and the questions that have to b faced, before and not after any considerable expansion of the research associations, are: first, will suc expansion affect adversely the fundamental researc at the universities, now seeking to make up for th lost years of war? And secondly, will such expansio yield higher dividends in creative work as well a productivity than a corresponding expansion o industrial research laboratories themselves, or if not then some alternative form of co-operative research such as the Mellon Institute type? In the presen man-power situation we cannot expand all thre types indefinitely; we must attempt to establis some order of priority based on an impartial critica survey.

In this speech, for all the appreciation of the valu of scientific research which it shows, Mr. Morriso passes over the seriousness of the man-power situation. Research workers, he said, must have th resources and status they need to keep up the flo of new and improved products, and he welcomed th improvement in the status and conditions of Britis scientific workers. He also stated that the Government has now decided that a larger share of buildin resources must be made available for the equipmen of research and other institutions likely to contribut to raising the productivity of industry.

That will be welcome news to some firms, whos plans for expansion and development have bee restricted by lack of such facilities, and by the polic laid down in the White Paper last spring. It must b remembered, however, that the major difficult experienced by the larger and the smaller firms alik is the recruitment of first-class men for research an development; and particularly from the universit schools of chemistry. If in consequence some firm who have recently been imbued with the resear spirit are driven to recruiting men of inadequa standing for their new research departments, the ne enthusiasm of those firms is likely to be damped, ar still more as the results may well fall short expectation.

Such factors may well lie outside the field of su a conference as that addressed by Mr. Morrison, b they should not be overlooked by one who carries large a share of responsibility for determining t distribution of the scientific effort of Britain at time when expansion in any one direction of necessi involves curtailment elsewhere. Nor can he w afford to disregard those factors which, like co ditions of service, may influence as profoundly Government policy the distribution of scienti workers in particular occupations. Quite apart fr the distribution of, say, the available chemists, b chemists and physicists between industry, academ research, the research associations and Governme departments, has any real thought been given, fr the national point of view, to the effect of unbalanc expansion of university departments of medicine comparison with their other scientific departmen or of the wide disparity in the inducements offered to the graduate in medicine as compared with those received by the chemist, biochemist or physicist ?

It is true that industry itself might well do something to redress that balance by the evolution of financial incentives, possibly of the invention-bonus type ; but those responsible for the scientific and industrial policy of the Government can no more ignore such considerations in determining the future of the research associations than they can the effect on the universities themselves of the conflicting and unco-ordinated pressures for expansion, on which the recent statement from Nuffield College on "The Problem facing British Universities" commented so pointedly. Dr. C. J. T. Cronshaw's remarks on this ubject to the Society of Dyers and Colourists in Bradford on October 7 should be noted in this onnexion, as should those of Sir Ian Heilbron at the nnual dinner of the Association of British Chemical Manufacturers on October 13.

A short-term policy which concentrates on securing the more effective utilization of existing knowledge may, as Sir Henry Tizard suggested in his presidential address to the British Association, be our immediate need from the point of view of increasing productivity and restoring the industrial health of Great Britain. In that policy the research associations have clearly a part to play, and the policy will simultaneously encourage the continuous application of science to ndustrial practice. That, however, does not mean utting research into the second place ; and such a hort-term policy must not be pursued at the expense f a long-term policy designed to ensure the nation a ufficient supply of scientific men and technologists in every sphere and to provide them with the equipment and resources they require. A long-term policy f that type can only be evolved as a result of the pen-minded study of the effectiveness of particular nstruments for our purpose, such as the research ssociations, in comparison with other methods. A esolute attempt must be made to decide where and ow creativeness and inventiveness are best fostered, and an impartial and continuing appraisal made of he demands of industry, the universities and the overnment services, and the interactions of those emands.

To achieve a reasonable balance is no easy task, ut no more urgent task awaits the Advisory Council n Scientific Policy than such a fundamental and mparative inquiry into the research association ovement in relation to other forms of co-operative d industrial research. Sir Henry Tizard, it would pear from his presidential address to the British ssociation, is ready to make that attempt ; the rd President of the Council might well support ch a task, for no other way seems so likely to tablish the best means by which during the next w critical years our limited resources in scientific an-power and equipment may be deployed so as to eld the quickest and largest return in productivity d in new and improved products. The inquiry uld not be an easy one ; and the evolution of a licy on the basis of its results could be undertaken ly at the highest levels.

ANTI-CANCER DRUGS

Approaches to Tumor Chemotherapy

A symposium of Papers and Discussions on various Aspects of Tumor Chemotherapy, developed from the Summer Meetings of the Section on Chemistry (C) of the American Association for the Advancement of Science at Gibson Island, Maryland, 1945–1946. Edited by Forest Ray Moulton. Pp. x + 442. (Washington, D.C.: American Association for the Advancement of Science, 1947.) n.p.

THE historical introduction to this series of papers is by the *doyen* of American cancer research, W. H. Woglom, who with brilliant lucidity and charming modesty of style describes the use of the innumerable agents of mineral, plant, animal or synthetic origin which have figured in the untiring attack on malignant disease by chemotherapy. He believes that hormone therapy has given the first hopes of ultimate success.

Algire discusses the method that he has developed of introducing a transparent chamber into a skin flap of the mouse, enabling the vascularization of transplanted tumours, or the regression of a tumour undergoing treatment with bacterial polysaccharide, to be observed. No doubt the method is a triumph of technique; but the photomicrographs are not very informative to the uninitiated and there is nothing startling about the discovery that the blood vessels rapidly develop to cope with the new growth ; further, is it really necessary, to-day, to introduce an illustration of a photomicrographic camera ?

Kopac's article is on "Cellular and Surface Chemical Aspects of Tumor Chemotherapy" ; it is no easy task to find one's way through the thirty pages of complicated laboratory data and question-begging hypotheses. His thesis seems to be that one group of chemotherapeutic agents acts by selective nucleoprotein dissociation. Although there are references to selective destruction of neoplastic cells *in vitro* by these compounds, no mention is made of the results of tests *in vivo*. It is to be feared that some hiatus was discovered between physico-chemical hypothesis and biological facts.

Aptekman uses an alcoholic extract of transplantable rat tumour to destroy grafted tumours in other rats; but his extract contained about 20 per cent alcohol which alone, apart from tissue constituents, could scarcely have been encouraging for the growth of the tumour.

Turner and Miller's paper on "The Chemistry of Substances Specific for the Stimulation of Lymphopoiesis and Myelopoiesis" describes the investigation of agents present in the urine of patients with myeloid leukæmia which produce myeloid metaplasia in the organs of experimental animals. Heinle, Hirschmann and Wearn also write on the myeloid metaplasia factor in human urine; but their work is obviously unfinished, for they state : "This issue obviously is not decided by the fact that the protein fractions prepared from various urines show great differences in biological activity. These observations, however, could suggest that the active principle in these fractions may possess the degree of structural specificity that one expects to find in a regulatory hormone." These two papers deal largely with the biochemistry of the substances from urine which influence the myeloid tissue ; on the other hand, the discussion which followed the papers centred around the interpretation of the pathological changes in the injected animals.

Tannenbaum, in his paper "Role of Nutrition in the Origin and Growth of Tumors", puts forward the evidence for his thesis that, in mice, a 60 per cent calorific restriction inhibits the development and reduces the incidence of spontaneous mammary cancer, and also retards the formation of induced skin, subcutaneous and lung tumours by hydrocarbons. Such experimental results are supported by statistical data from insurance companies which indicate that overweight human subjects are particularly liable to cancer.

Opie, in "Influence of Diet on the Production of Hepatic Tumors induced by *p*-Dimethylaminoazobenzene", states that a rice diet facilitates tumour formation, and that kidney and liver in the diet inhibit it, as do also riboflavin and nicotinic acid. A low-protein or high-fat diet was favourable to tumour production, whereas a high-protein or low-fat diet effected some retardation. Diets that protect against cirrhosis also protect against neoplasia; but tumours can arise in the absence of cirrhotic changes.

A group of papers by Lewisohn, Laszlo, and C. and R. Lenchtenberger, taking up, with discussion, sixty-eight pages, on "Chemotherapeutic Regressions of Transplanted and Spontaneous Cancers in Mice", deals with the use of the *L. casei* factor (folic acid) as inhibitor. Their results are severely criticized in papers by Sugiura and by Zahl and Hunter, who find no convincing evidence that this substance does, in fact, inhibit tumour growth.

A historical account is given by two descendants of William B. Coley of his treatment of malignancy by bacterial toxins. There follows a series of papers (45 pages) by a large group headed by Shear, bearing the resounding title of "Some Aspects of a Joint Institutional Research Program on Chemotherapy of Cancer: Current Laboratory and Clinical Experiments with Bacterial Polysaccharides and with Synthetic Organic Compounds". Unfortunately, this monument of organisation and industry has not as yet yielded chemotherapeutic results of proportional significance. One is tempted to ask whether it is really necessary to reproduce a photograph of a small bottle bearing the legend, "Sterile solution of polysaccharide prepared for clinical use. Sterile cotton plugged needle, inserted through the outer region of the rubber stopper, extends into the bottle."

More than a hundred pages are devoted to a number of papers on nitrogen mustards (chloro-ethylamines) for the treatment of lymphomas, leukæmia and allied conditions. The energy expended in these investigations and in the preparation for publication must have been immense; nevertheless, the opinion has been expressed by some authorities that the mustards are not superior to X-rays in the treatment of these types of malignancy.

Huggins, in an admirable paper of four and a half pages, describes the "Antiandrogenic Treatment of Prostatic Carcinoma in Man"; more space might have been given to an account of this valuable contribution to tumour chemotherapy. Reinhard and Womach describe the application of radioactive phosphorus to the treatment of leukæmia, Hodgkin's disease and polycythæmia, of which only polycythæmia is benefited by this agent.

The two papers by British investigators, Haddow and co-workers, and Parry and Innes, dealing with the use of urethane in the treatment of lymphatic and myeloid leukæmia, lead to the conclusion that the drug certainly has a temporary ameliorative effect on the disease; but unfortunately the improvement is not maintained.

Engelbreth-Holm and Stamer's paper is on the somewhat heroic treatment of leukæmia with the most powerful carcinogen (9 : 10-dimethyl-1 : 2-benzanthracene); one of the patients was still alive eighteen months after treatment.

Geschickter and Reid contribute an account of the use of oil-soluble organo-metallic compounds in malignancy; iron, cobalt, copper, manganese and nickel were given in the form of fatty-acid–phthalate derivatives. Leukæmias responded favourably to these substances, as they do indeed to other drugs and radiations.

Much of this book, or rather collection of papers, makes tedious reading, for a large part consists of detailed technicalities somewhat distantly related to the aim expressed in the title. It is doubtful if the verbose accounts of laboratory or clinical findings will interest any but the pure specialists, which may help to explain why the verbatim reports of the discussions which followed the papers are nearly always more interesting than the papers themselves.

I. Hieger

TESTING PETROLEUM HYDROCARBONS

Standard Methods for Testing Petroleum and Its Products

Ninth edition. Pp. xlviii + 616. (London: Institut of Petroleum, 1948.) 31*s*.

THE first edition of "Standard Methods" appeared in 1924, initially at the instigation of Sir Boverton Redwood and following labours of the pionee committee under Prof. Brame. During the ensuing twenty-four years the volume has steadily grown i stature and authority; once again, in this ninth edition we recognize a mandate for laboratory procedure which for long past has commanded international respect. As is the case with preparation o other 'standards', whether governing quality o materials or guiding methods by which that quality is assessed, few realize the enormous amount of wor put in voluntarily by specialists representing every possible angle of the subject concerned. Standardization committees are notoriously time-consuming bodies, and this particular case has clearly been n exception; apart from the main committee, no les than sixty-two sub-committees, panels and working groups, involving some two hundred and sevent experts, contributed to this considerable task, an it may be said at once that it has been worthil discharged.

Naturally the technician familiar with previous issues of this volume will want to know wherein differs from its predecessors. Only two method have been withdrawn, namely, acetate content o solvents and halogen content in lubricating oil. Th new methods comprise determination of chlorine i lubricating oil, knock-rating of aviation fuels (ric mixture), lead, copper and iron in lubricating oil, oil separation on storage of grease and spectrograph analysis of inorganic constituents of ashes; this la is a welcome inclusion of a technique now so free employed in inorganic analysis.

Revision of existing methods affects the corrosi test for lubricating greases, diluent content of cran case oils (Diesel fuel diluent), distillation of cut-ba bitumen and road oil, ignition quality of Diesel fuel, knock-rating of aviation fuels (weak mixture), knock-rating of motor fuel, penetration of greases and petroleum, saponifiable matter, smoke-point and unsaponifiable matter in drying oils. Some minor alterations concern thermometers employed in determination of specific gravity ('I.P. 46W. Gravity Balance') and specific refractivity ('I.P. 45W. Refractometer').

The format of this volume follows much the same pattern as the eighth edition. Both arrangement and indexing reflect great credit on the editorial sub-committee and permanent officers of the Institution concerned. No one involved in routine investigation of petroleum and its products can afford to be without this latest "Standard". H. B. MILNER

CHEMISTRY OF ACETYLENE

The Chemistry of Acetylene and related Compounds

By Ernst David Bergmann. (Polytechnic Institute of Brooklyn: Lectures on Progress in Chemistry.) Pp. vii + 108. (New York and London: Interscience Publishers, Inc., 1948.) 18*s*.

THIS book is the latest representative of a series of short lecture-monographs. The title would seem to be rather grandiloquent for a work of this type; but, in fact, the author has managed to consider, albeit superficially, most of the reactions and transformations of this important class of organic compounds.

The first lecture enumerates the thermodynamical and physical data connected with the triple bond and also deals with addition to acetylenes, the 'iso-acetylene' hypothesis and the reactions exhibited by compounds containing the ethynyl group. The second discusses the addition of nitrogen compounds to acetylenes and then proceeds to give an admirable précis of the researches of Reppe. The work of the Weizmann school is described a little over-enthusiastically; but this is perhaps natural in a publication by one of its members. This latter section serves a useful purpose in making available the results of this school in a form for easy reference; hitherto they have been scattered throughout the patent literature. Many tantalizing references to unpublished work are mentioned; in particular, one awaits with coniderable interest the details of the vapour-phase somerization of dimethylethynylcarbinol to β-methylrotonaldehyde. The last lecture describes the nature of the condensation catalyst employed by the Weizmann school and continues with a discussion of cetylenic polymers, including vinylacetylene and *yclo*octatetraene; the book ends with a brief account of naturally occurring triply-bonded compounds. References are amply provided throughout.

The book is written in a highly personal manner, nd many of the mechanisms accepted by the author must be considered to be still *sub judice*. The style on the whole clear and concise, although irritating edantries occasionally occur (for example, the use of 'analogon' for the far more usual 'analogue'). Over-compression has rendered one sentence (p. 88) completely beyond comprehension. The author ucceeds in conveying the spectacular synthetic possibilities of the acetylenic compounds and the imulating experience of working in this field.

R. A. RAPHAEL

THE ANODIZING OF ALUMINIUM

Werkstoff Aluminium und seine anodische Oxydation

Ein Handbuch und Ratgeber für den Praktiker. Von Dr. Max Schenk. Pp. 1042. (Bern: A. Francke A.-G., 1948.) 138 Swiss francs.

ALTHOUGH information on the technical reinforcement of the oxide film on aluminium and its alloys is to be found in papers in scientific publications, articles in trade journals, and patent specifications, it is often difficult to trace, and books on the subject are not numerous. The issue of Dr. Max Schenk's book, dealing with the subject comprehensively and critically, and written by an author having a wide knowledge of the processes involved, is therefore to be welcomed. It is primarily intended for the practical man, but is no mere compendium of technical processes and applications. Dr. Schenk holds the view that to understand the processes involved, to operate them successfully, and to make full use of the product, requires considerable knowledge of the chemistry and physics of aluminium and its compounds, coupled with some acquaintance with the various processes of fabrication to which the metal may have been subjected. The book accordingly comprises two sections, approximately equal in length, the first dealing with the structure, properties, and fabrication of the metal, and the second with the chemical and electro-chemical processes used to produce coherent oxide films and with the properties and applications of the product.

The first quarter of the book is devoted to the metallography and fabrication of aluminium and its alloys, and covers constitution, casting, rolling, heat-treatment, forming and methods of jointing. The descriptions of the processes are short but adequate, and the treatment is essentially practical. Thus figures and diagrams are given showing the effect of alloying and of processes such as cold working and heat treatment on the structure and properties of the product, while current theories on these subjects are given in outline but are not discussed at length. Stress is laid throughout on the behaviour of the product during anodizing, special attention being given to the effects of variations in processing conditions and of faults during fabrication. Useful tables are included giving the compositions and properties of commercial cast and wrought alloys, though so far as British alloys are concerned the list is by no means complete. Recommendations are also made for optimum working and annealing conditions, and for solution and precipitation treatments in the case of the heat-treatable alloys.

The next part of the book is devoted to general chemical theory, particularly electrochemistry, and is followed by an account of the chemistry of aluminium and its compounds. This section is comprehensive, clearly written, and well illustrated; and the chapters on the formation and properties of the oxide film should lead to a clear understanding of the technical processes and applications of anodizing. The section dealing with the chemical behaviour of aluminium and aluminium alloys towards various reagents includes no less than sixty-three pages of tables. The chapters on corrosion are detailed and lucid; but their value is lessened by the fact that research by other than German workers has been largely ignored.

The next section of the book, dealing with technical methods of forming the oxide film, opens with a short but excellent account of the purely chemical processes, followed by a description of the nature and properties of films formed in various electrolytes under the application of direct or alternating electric current. The treatment is lucid and comprehensive, covering both theory and practice, and serves as an excellent introduction to a very detailed account of the commercial anodizing processes. This covers pretreatment, plant installation, operating conditions for various electrolytes, and after-treatments such as sealing, dyeing, and impregnation with inorganic pigments. Practical difficulties, whether arising from faults in the material or from errors during anodizing, are dealt with at length, and information is given on plant and process control, and on the testing of the product. The sections on process control are excellent; but those on testing leave something to be desired. Physical tests on anodized material are adequately described; but for assessing liability to corrosion, only accelerated tests such as the Mylius are considered, and nothing is said about their reliability. For chemical control of the metal to be anodized, the reader may be led to infer that qualitative spot tests are generally sufficient and that full quantitative analyses are rarely needed.

Applications of anodized aluminium in household ware, architecture, instrument-making and chemical plant are critically described, with reasoned statements on the most suitable type of film for each purpose. The book concludes with a chapter on the cost of plant, operation and upkeep.

The printing, binding and quality of illustrations leave nothing to be desired, even by pre-war standards, and one can only regret that the book is not in English and that the price is so high.

H. W. L. PHILLIPS

TAXONOMY AND EVOLUTION OF COTTON

The Evolution of Gossypium

And the Differentiation of the Cultivated Cottons. By J. B. Hutchinson, R. A. Silow and S. G. Stephens. Being the Final Report of the Genetics Department, Cotton Research Station, Trinidad, B.W.I. Pp. xi + 160. (London, New York and Toronto: Oxford University Press, 1947.) 15*s*. net.

THE function of the Empire Cotton Growing Corporation is to assist in the promotion of cotton-growing in the various countries of the British Empire or Commonwealth. This aim is largely realized by close co-operation with the local governing authorities in the various territories, by carrying out a wide programme of research designed to maintain or improve the quality of the crops and to increase yield by selection and initial expansion of new seed stocks, by overcoming and circumventing pest and disease attack, and by effecting improvements in many aspects of tropical and sub-tropical crop husbandry. The Corporation started a main Cotton Research Station in Trinidad in 1926 and encouraged fundamental studies in botany, plant physiology and genetics so that cotton breeders would have firmer foundations for their work on the commercial cotton crops. The increasing complexity of many modern problems necessitates a considerable extension in this side of the work of the Corporation. The Trinidad Station has been closed and a new, larger station is being established in Uganda, where closer contac with the field-workers in Africa may be made.

The transfer of activities from Trinidad to Ugand has caused a temporary but unavoidable halt i many activities. The joint authors of the book unde notice have therefore taken this opportunity t review the progress made while they were working a a team in the Genetics Department in Trinidad, an to survey many lines along which future researc could be usefully directed. Many of the authors detailed investigations have been published separatel from time to time. The present work reviews th genus *Gossypium* as a whole by covering its classification, evolution and present position on a basi broadened by critical use of much published work o other workers. For convenience, the book is divide into four main sections.

"The Wild and Cultivated Cotton Plants of th World" (1907), by Sir George Watt, is the almos classical monograph on the taxonomy of cotton. I the light of more recent advances in the field o genetics and cytology, coupled with morphologica considerations, Hutchinson has revised the classification of the genus on a simplified basis, dividing i into eight sections, of which two contain the cultivated commercial cottons and six embrace the wil species.

The evolution of cotton is covered by Hutchinso and Stephens. Consideration is given to the identification of the major factors which governed th evolution of true 'commercial' cottons from the wild and often virtually lintless, species. The origi of first the Old World cottons, with the basic chromosome number in the genus of $n = 13$, and then th New World cottons, with $n = 26$ chromosomes comprising a set of thirteen homologous with th genom of the cultivated Old World species and a se of thirteen homologous with that of the wild America species, will prove of interest to many ethnologist as well as to biologists.

These evolutionary studies are pursued further b Hutchinson and Silow in the third section, which covers the differentiation of cotton, as the spinne knows it, into the complex of major and minor type by man.

In the last section, Hutchinson and Stephens consider how new characters arise and the part playe by polyploidy. Brief consideration is given to th nature of genetic variability and to the question o its often desirable conservation when it may ai adaptation to varied local conditions. Many of th views expressed should be of both practical an general interest to breeders working on the presen commercial types.

No doubt individual workers in the genetics c cotton may disagree in part with particular view held by the authors; but agreement will be gener that a work of this type was long overdue, and tha it will facilitate adequate interpretation of the man contributions made in this field in recent year From the angle of the textile technologist, the basi groundwork of cotton genetics may seem to be matter of academic rather than of practical interes Nevertheless, only fundamental studies in the fiel mentioned above will make it possible to effec major improvements in the present cottons of commerce by the formation or transference of desirab fibre characteristics, by inducing immunity to diseas or resistance to pest attack, or by obtaining increase yields through greater adaptability to varied growt conditions.

E. LORD

Physics

For Students of Science and Engineering. By Asst. Prof. William H. Michener. Pp. x+646. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1947.) 25*s.* 6*d.* net.

THIS is a text-book, of about intermediate standard, in which physical principles are illustrated more fully than usual by examples from everyday life. The author claims that he has tried to encourage the student to think for himself, and o this end has used the device of mentioning phenomena without explaining them. It is doubtful whether this device is successful. For example, the problem of a ping-pong ball supported on a jet of air (p. 135) is not one that the student should be expected to work out for himself; nor is that of the oncentration of the scattering by a diffraction rating into one particular order (p. 353). Topics such as these are best omitted completely in an ntermediate text-book.

Some of the diagrams are rather poorly drawn. On p. 343, for example, a lens system is shown with ll the deviations produced at a single surface of each lens. On p. 364 a ray of light is shown being dispersed into three representative rays at one surface of a prism, these three then emerging from the other surface *parallel to each other*. Further, these parallel rays are caused to diverge by a converging lens! Such diagrams place the serious tudent at a disadvantage with respect to the casual eader.

In short, this text-book has some serious faults and does not appear to have any particular points to ommend it in competition with the many others that exist.

Soilless Growth of Plants

y Carleton Ellis and M. W. Swaney. Second lition, revised and enlarged by Tom Eastwood. p. x+277. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1947.) 28*s.* 6*d.* net.

HYDROPONICS, or soil-less culture, has made considerable progress during the last ten years, specially in America and in areas where heat and rought make it difficult to produce vegetables under rdinary conditions of soil cultivation. While the rst edition of Ellis and Swaney's book catered ainly for the amateur or general reader, Eastwood's vision deals largely with the commercial side. This vision has been so drastic that little of the original xt remains; but there is no indication of this in he foreword or elsewhere, thus failing to give due redit to the original authors.

Many types of equipment have been developed for ub-irrigation and gravel culture methods, and in scribing these, Eastwood indicates the weak, as ell as the strong, points of the outfits, with the robable causes of failure where initial success has ot been followed up in later work. Specially valuable e the practical working details for procuring the ecessary chemicals, making up and analysing the utrient solutions and the care of the apparatus eded. Plants grown in soil-less culture are not mmune to many of the common pests and diseases, is too often believed, and precautionary methods gainst them are suggested.

With the growing interest in soil-less cultures, this vision should be of much value to scientific workers, mmercial growers and amateurs alike, as its insistence on practical details should help to overcome many of the difficulties inherent in the method. As a work of reference it should also play its part in the considerable advances that may be expected in hydroponics in the course of time. W. E. B.

The Ventilation of Bee-Hives

By E. B. Wedmore. Pp. 116. (Petts Wood: Bee Craft, Bracken Dene, Manor Way, 1947.) 7*s.* net.

MR. WEDMORE has done a further service to beekeepers by bringing together, discussing and criticizing in his latest book the available data on the subject of hive ventilation. This is a subject to which Mr. Wedmore has devoted considerable time and on which he speaks with authority. It is, of course, of the very greatest importance to a proper understanding of those conditions which are necessary to ensure satisfactory living conditions for colonies of hive-bees both in winter and summer.

The reader will be left in no doubt that the conclusions reached from analysis of the data on hive ventilation, which have so far been obtained, clearly support the application of the relatively spartan methods of wintering bees which are to-day advocated almost unanimously by the leading authorities both in Europe and in North America. It is of interest to students of beekeeping practice to note that these methods, which are still regarded with suspicion by some beekeepers, were employed and recommended by leading beekeepers so long as fifty years ago.

Besides discussing such matters as the form of the winter cluster, air currents within the hive, the disposal of water and carbon dioxide, and temperature control, the author also discusses such a practical matter as hive design.

This is a most stimulating book not only on account of the interesting analysis of the data presented but perhaps even more because of the gaps in our knowledge which such analysis discloses.

C. G. BUTLER

Genetics

By Dr. H. Kalmus, in collaboration with Lettice M. Crump. (Pelican Books, A.179.) Pp. 171. (Harmondsworth: Penguin Books, Ltd., 1948.) 1*s.* 6*d.*

GENETICS is one of the youngest, yet also one of the most actively developing, branches of biology. At present neither its own theoretical structure and internal consistency nor its importance for general biology and human affairs is widely appreciated outside the immediate circle of geneticists themselves. This is in a great measure due to the lack of books giving simple accounts of the subject, particularly in its broader connexions.

Dr. Kalmus' 'Pelican' should therefore command a wide audience. It is a formidable task to compress even an outline of genetics into 171 pages, and there are inevitably omissions and over-simplifications. The author is, however, to be congratulated on his attempt to include consideration of the wider implications as well as the narrower basis, even though in places his discussion may not commend itself to all his fellow geneticists. Care is taken to explain the genetical terms used, and a short glossary is given as well as suggestions for further reading. It has, however, proved impossible to explain all the more general biological terms which are used. The book, therefore, may well prove to be of greatest value to those who already have some biological background.

MOVEMENTS OF POPULATION IN THE BRITISH COMMONWEALTH

AT the Brighton meeting of the British Association, a symposium was arranged by Section E (Geography) on population movements in the British Commonwealth. Prof. C. B. Fawcett contributed a paper on the geographical aspects of the subject; Prof. Brinley Thomas (Section F: Economics) dealt with it from the point of view of an economist; and Mr. R. R. Rawson analysed the particular problem of White settlement on inter-tropical highlands, with special reference to Kenya and Rhodesia.

Prof. Fawcett introduced his analysis with the main facts about the distribution of population in the Commonwealth. He described it as the least densely peopled of the major political units of the world. More than half the total area consists of the arctic or sub-arctic regions of Canada, or the arid and semi-arid zones of Australia and South Africa. The Dominions, the total area of which covers about one-seventh of all the inhabited land, contain not more than one-fifteenth of the good agricultural land of the world. England, with its 40 million people on 50,000 square miles of land, that is to say, about 800 persons a square mile, is the most densely settled country in the world. The striking unevenness of the distribution of the population of the Commonwealth raises the question whether the younger Dominions are under-peopled.

In considering this very topical problem, Prof. Fawcett saw reason to approve measures such as the 'White Australia' policy. He stressed that any 'foreign' minorities which remain distinct communities in the population tend to lessen its social and political unity, and that the acute colour problems in South Africa and the United States are an object-lesson which justify Australians in their determination to keep out races difficult to assimilate. Prof. Fawcett doubted whether the economic effects of immigration are the most significant ones. To quote his words, "the colour problems of the United States and the communal differences of India are sufficient evidence that the world has not yet reached the level of civilization in which a plural society, with wide cultural or racial difference between its component communities, can form a satisfactory social or political unit of free people".

Prof. Fawcett cited with approval the following estimates of the probable populations which the Dominions could support at the present standards of living: Australia, 30–50 million; Canada, 60–100 million. In Australia the increase could be brought about in three ways: by closer rural settlement in the well-watered areas, expansion of tropical agriculture in the east coastal areas of Queensland, and industrial development based on mineral resources, especially coal. Britain could not be expected to supply agricultural migrants, in view of the drive to grow more food at home. Similarly, while full employment continues, there would be little chance of a large-scale transfer of industrial workers. After referring to the effect of social security and the demographic consequences of the pre-war fall in the birth-rate, Prof. Fawcett concluded that any considerable migration would accentuate the change in the balance between the lower and upper age-groups.

The next paper, "The Economics of Commonwealth Migration", was read by the present writer. The argument may be summarized as follows. Despite all the efforts made to people the Dominions wit migrants from Britain, there was a net overflow o population from the British Empire to the rest o the world amounting to 5·9 million in the year 1836–1900 and 250,000 in the period 1901–36. O the ten million British people who crossed the sea in the half-century 1845–1894, 68 per cent went t the United States, 16 per cent to Australia and New Zealand, and 12 per cent to Canada.

What were the main determinants of thes migration movements ? First, there was a shar difference between the relative quantities of factor of production in the Old World and in new countries the marginal productivity of labour overseas wa much higher than it was in Europe. Secondly capital exports tended to be accompanied by migration of labour. The last great burst of emigration from Britain coincided with the absorption of considerable volume of capital by Canada, when th Prairie Provinces were being opened up in the earl years of this century. Thirdly, the *direction* of th flow of British emigrants was strongly influenced b the contrast between the high degree of equality o opportunity in the United States and the clas barriers in Great Britain. Under the influence of th ideas of Edward Gibbon Wakefield, British colonization policy was designed to reproduce in the overse dependencies the social structure of the homelan It met with little success because the facts in th Colonies were too strong for it. It was the discover of gold, not the colonization theories of Whitehal which gave a real impetus to the growth of Australia

The inter-war period was dominated by the drasti immigration restrictions introduced by the Unite States in 1924. The consequences were far-reachin Agricultural protectionism was stimulated in Europ and capital from the United States was encourage to flow to the Old World, since population wa prevented from migrating to America. In these ne circumstances the Empire settlement policy launche by the British Government led to disappointin results. The net amount of British emigration to th Empire fell from 113,000 in 1922 to 63,000 in 1929 and during the thirties the stream actually turne the other way, Britain receiving an *inward* balan of 126,000 migrants from the Dominions.

A cardinal weakness of the ideas underlying th policy of peopling the Empire was the failure realize that Britain was no longer able to expo capital on the appropriate scale. Moreover, a sign ficant change was taking place in the econom relationship between agricultural and industri countries. As the Western world became richer, greater proportion of income was being devoted amenities, and a smaller proportion to necessitie hence the growth of employment in personal service distribution, entertainment, etc. Despite this tren Empire migration policy continued to be based extensive land settlement in the Dominions. Th objective was not consistent with the new directi which was being given to the productive forces the Western world by the rising level of affluence.

Against this background, the paper proceeded an analysis of the bearing of migration on the curre economic crisis, the hypothesis of a planned trans of population for strategic reasons being left out account. Large-scale emigration would weaken t lower age-groups which contain the most producti labour. It would be accompanied by an export capital which would accentuate Great Britai difficulties. In 1947, a year of severe crisis in t balance of payments, no less than a third of the toll on British reserves was caused by export of capital, a good proportion of which consisted of emigrants' funds and money invested in Dominion securities. Moreover, by accentuating the scarcity of man-power in industries where the shortage is already keen, emigration tends to promote inflationary pressure.

The policy best calculated to help Britain overcome the crisis is one which would welcome appropriate grades of immigrants from the continent of Europe. A high rate of immigration makes up for a low degree of internal mobility. The argument that these newcomers would be a strain on the British economy since they have to be fed and housed does not bear analysis. They are prepared to work in industries producing the most essential output—coal, textiles, food—and they are accommodated in existing premises. The value of the marginal product of immigrant labour of this kind much exceeds the cost of the imports and capital equipment needed for its employment.

Finally, there is the long-run question whether Britain can hope to sustain a population of fifty million at anything like the old standard of living when outside help is no longer available. Much will depend on the future course of the terms of trade. There are strong reasons for taking a pessimistic view. The industrializing of agricultural countries will tend to reduce exports of food from these countries. A study of the stages through which the United States has passed is instructive. In poor countries like India, the peasants may sell less of their crops on the market as the price improves; they will wish to consume more themselves. Then, the principle of 'fair shares' in the allocation of food as between rich and poor nations augurs ill for the highly industrialized countries like Britain. These tendencies operating unchecked mean a continuance of dear food for the British people: whether this can be masked indefinitely by a policy of internal subsidies is questionable.

On the other hand, it may be that the world is on the eve of a great advance in the application of science to crop production. Moreover, the long-term trend in consumption habits noted in the inter-war period may yet reassert itself. The most reasonable expectation is that the terms of trade for Britain will fall somewhat from their present level, but will never again reach the favourable ratio experienced between the two World Wars. If the people respond to this stern challenge by increasing and rearranging their productive power, there is no reason why a tolerable equilibrium cannot be found for a population of fifty million. There need be no mass emigration.

In the third paper in the symposium, Mr. R. R. Rawson considered in detail the factors determining White settlement in Kenya and Rhodesia. Looking to the future, he saw signs of a more considerable White settlement in East Africa for strategic reasons; but in view of the lack of mineral resources in Kenya, such a plan would entail linking Kenya with the coal and iron deposits of Rhodesia.

The open discussion ranged widely over the ground covered by the three papers. One of the questions treated in detail was the future of the terms on which Britain can expect to purchase imported food. Reference was made to the views of authorities in other Sections of the British Association, who had pointed out that the effective supply of food could be greatly increased if the heavy loss due to destruction by vermin could be partly eliminated. It was significant to observe the attention devoted to the food problem in this symposium, as in other sessions during the British Association meeting at Brighton. On the question of the White Australia policy, a representative of Section H (Anthropology) disagreed with Prof. Fawcett and argued that the difficulties of assimilating coloured peoples must not be shirked. Finally, I had the feeling that Prof. Fawcett's suggestion that Australia could increase her population to 30–50 million, and Canada to 60–100 million, was much too optimistic. A careful assessment of the probable economic trends seems to be necessary before such estimates can be put forward with any confidence.

BRINLEY THOMAS

PHYSICAL CHEMISTRY OF PROCESS METALLURGY

THE discussion on "The Physical Chemistry of Process Metallurgy", which the Faraday Society held at Ashorne Hill, Warwickshire, during September 23–25, showed plainly that process metallurgy is now as much the province of the physical chemist as the metallurgist. Attention at this meeting was devoted almost entirely to the high-temperature processes involved in the winning and refining of metals, and here in particular it seems that advances will come mainly from the application of physical chemistry. Indeed, speaking as a steelmaker, Sir Andrew McCance (Colvilles, Ltd.) confirmed, in his introductory remarks, that the advances in the open-hearth process over the past twenty years have come almost entirely from the physico-chemical approach to open-hearth reactions. In this article it is intended to touch only upon the main topics of physico-chemical interest. In so short a space it is impossible to consider all the problems discussed, and reference will not be made to those papers concerned with industrial applications.

After an opening paper by Sir Charles Goodeve (British Iron and Steel Research Association), outlining the physico-chemical principles of special importance in this field, the subject was considered in three main sections: metallic solutions; roasting and reduction processes; and slags and refining processes. In addition, a number of papers dealt with the problems associated with experimental work in the important temperature-range between 1,000° C. and 2,000° C. The main difficulty in handling substances at these high temperatures is finding refractory containers which will not react with them. Almost all substances become chemically reactive in such extreme conditions, since high activation energies for molecular processes are no longer seriously restrictive. Another less obvious problem, which has caused large errors in the results of many equilibrium studies between gas mixtures and metals or slags, is thermal diffusion. This is caused by the large temperature gradients which are generally unavoidable in any apparatus operating under these conditions. The heavier components in the gas mixtures used diffuse away from the hot zone, and so set up concentration differences in the apparatus which may be maintained even under steady flow conditions. These differences can be avoided by combining adequate preheating of the incoming gas with a flow-rate sufficient to prevent any significant concentration gradients from becoming established. They can also be greatly reduced, as shown by Mr. M. N. Dastur and Prof. J. Chipman (Massachusetts Institute of Technology) in a paper dealing specifically with the problem, by the addition of a heavy inactive gas, such as argon, to the mixture.

The present state of our knowledge of solid metallic solutions is rather different from that of liquid solutions. For solid solutions we frequently have a structure which has been determined precisely by X-rays, and an exact knowledge of the conditions under which one structure becomes unstable relative to another. As pointed out by Dr. R. M. Barrer (Bedford College, London), simple spatial considerations, such as the ratio of the radius of the interstitial atom to that of the metal atom, lead to a reasonably clear understanding of the type of structure which will be assumed. In contrast, our knowledge of the chemical potentials of solutes in such solid solutions is fragmentary, to say the least. In the liquid state the reverse is the case; for, as Prof. Chipman showed, there are now a reasonable number of such solutions for which the thermodynamic data are satisfactory. On the other hand, we have no exact model for our liquid solution, and can only suppose that it differs from the solid mainly due to the relaxation of spatial restrictions, brought about by melting. This accounts, of course, for the marked increase on melting in the solubility of substances present as interstitial atoms; but this very relaxation makes it difficult to interpret the marked effect of one solute on the activity of another, as described in the papers by Prof. Chipman and by Dr. J. A. Kitchener, Dr. J. O'M. Bockris and Mr. A. Liberman (Imperial College, London).

From the point of view of process metallurgy, kinetic aspects are mainly of interest at low temperatures in the solid state. At high temperatures, diffusion usually controls the rate for processes involving solids, and convection for those involving liquids. This can readily be appreciated when it is remembered that at 1,600° C., for example, no less than one collision in 10^6 is energetically suitable for an activation energy of 50 kilocalories, as compared with one in 10^{14} at 500° C. The most commonly investigated property of solid solutions is the diffusion of solute atoms in the metal lattice. The property most frequently measured, however, is the movement of the solute through a thin sheet of metal; but this, as Dr. Barrer stressed, is often governed more by surface processes than by lattice diffusion. A good example was provided by Sir Charles Goodeve and Mr. K. H. Jack (British Iron and Steel Research Association), who reported that the slowest step in the evolution of nitrogen from an iron–nitrogen alloy (the ε phase of the iron–nitrogen system) is the combination of pairs of nitrogen atoms at the surface. In the presence of hydrogen gas, which appears to render this combination process unnecessary, the evolution is 10^4 times faster, and lattice diffusion becomes rate-determining to some extent.

The value of thermodynamics in the design of metallurgical processes was brought out strongly in the section on roasting and reduction. Its application is particularly important in the reduction of refractory oxides for winning such metals as magnesium, titanium and vanadium. A good example was provided by Prof. L. M. Pidgeon and Dr. J. A. King (Toronto), who reported their studies of the equilibrium:

$$2MgO + 2CaO + Si\,(Fe) = Ca_2SiO_4 + 2Mg_{(g)} + (Fe).$$

This is the basic reaction for the Pidgeon process, which was used in Canada during the War for making magnesium from dolomite and ferrosilicon. The pressure of magnesium developed by this reaction at 1,200° C. is 19 mm., as compared with 1·9 mm. for the reaction,

$$4MgO + Si = 2Mg_{(v)} + Mg_2SiO_4,$$

which was investigated in Germany in 1940. The reason for the difference lies, of course, in the far more negative free energy of formation of the calcium than the magnesium silicate.

The method of representation of free energy data is important for those concerned with the extractive processes. Two methods were discussed at the meeting; one the plot of ΔG° against T, which was illustrated by Prof. C. W. Dannatt (Royal School of Mines, London) and Dr. H. J. T. Ellingham (Royal Institute of Chemistry, London) in their introductory paper to this section, and the other the plot of $\log K$ against I/T, which was used by Dr. M. J. N. Pourbaix and Madame C. Rorive-Boute (Brussels) in describing a series of oxide systems. Although each method has its merits, it would seem desirable to select one as standard, since the graphical representation of collected data is certain to become of increasing importance. In the light of the discussion, the ΔG°, T plot would seem to be of more general application, since it can include data for a wide variety of systems in one diagram. With complex processes this makes it possible to distinguish at a glance the important equilibria from the unimportant, and to see how the systems change as temperature and pressure are altered.

Dr. P. Gross and Messrs. C. S. Campbell, D. L. Levi and P. J. C. Kent (Fulmer Research Institute) reported some interesting work on the thermodynamics of aluminium halides by measurements of the reaction pressures set up by equilibria of the type:

$$NaCl_{(solid)} + Al_{(liquid)} = Na_{(vapour)} + AlCl_{(gas)}.$$

Direct measurements of the pressure are not possible on account of the reactive character of the halides, so they had to adopt an unusual experimental technique. The unknown gas–solid equilibrium, together with a known one which does not interfere with it, was allowed to establish itself in an evacuated vessel closed except for a capillary outlet. This outlet served as a slow escape for the equilibrium gas mixture, which was collected in a suitable condenser on emerging from the capillary. The ratio of the unknown pressure to the known was determined by analysis of the condensate, the known pressure in this case being the vapour pressure of the alkali halide.

The primary reactions which occur in roasting and reduction processes were described by Dr. J. S. Anderson (Atomic Energy Research Establishment, Harwell) in terms of the lattice defects which can occur in ionic crystals, and particularly oxides and sulphides. For these materials the stoichiometric compound is a special case, and in general there is either a very small excess of oxygen in the lattice associated with cation holes, or excess of metal as interstitial metal atoms. In the light of this knowledge the reduction process may be considered as taking place in the following stages. First there is chemisorption of hydrogen or carbon monoxide at the surface as hydroxyl or carbonate ions, as proposed by Garner, the additional valence electrons being accommodated by lowering the valency of one or more cations and thus creating lattice defects in the surface. These defects now migrate into the lattice and increase in concentration until saturation is reached, and metal or lower oxide forms as a new phase. In roasting sulphides one would similarly expect that oxygen ions would first be formed on the surface, creating cation holes within the lattice. This would be followed by destruction of the positive holes as oxides of sulphur are eliminated, and the resultant building of oxygen into the lattice in place of sulphur. Studies of the roasting of copper sulphides by a new method reported by Prof. E. A. Peretti (Notre Dame, Indiana) are in line with his picture, for they show that the reaction proceeds directly from cupric to cuprous sulphide and finally o cuprous oxide, and not via the formation of sulphates as previously believed.

Our present understanding of liquid slags is far from adequate. This can be attributed partly to the fact that ionic melts in general have received little attention from the physical chemist, and partly to he great difficulties which arise in making controlled experiments with materials which attack containers of all types. As Dr. F. D. Richardson British Iron and Steel Research Association) pointed out, our ideas of liquid slag structures are based essentially on our knowledge of the structures of crystalline silicates, phosphates and aluminates, and the recognition that the liquid state differs from he solid mainly in lacking any long-range order. This picture is corroborated by X-ray work on silica lasses, which have been shown to consist of random networks of silicate tetrahedra with metallic cations located in the holes between them. The chemical potentials of the components of slags have in some cases been determined by slag-metal equilibrium measurements. For binary systems they can be obtained less directly from phase diagrams, and interesting results derived in this way were reported by Prof. M. Rey (École des Mines, Paris). The tandard states for some of the oxides and sulphides of importance in slags present a problem in cases uch as ferrous oxide (FeO) and iron sulphide (FeS), which can exist over wide ranges of composition depending on the equilibrium oxygen or sulphur pressures. Although failure to take account of such non-stoichiometric variations may not lead to large rrors in total free energy changes, it was stressed by Dr. G. M. Willis (Melbourne) that large errors may be caused in the partial molar free energies of components in slag melts. An ionic view of slags has been developing in recent years, and although, as Prof. E. A. Guggenheim (Reading) pointed out, it is irrelevant, so far as slag-metal equilibria are concerned, whether the various atoms or atom groupings are ionized or not, knowledge of the ionic constitution is helpful in developing a detailed model of slag melts, nd may, indeed, be of practical importance in arc furnaces. Dr. J. A. Kitchener, Dr. J. O'M. Bockris and Messrs. J. Tomlinson and S. Ignatowicz (Imperial ollege, London) reported measurements of the electrical conductivity of binary silicate melts, which indicate that the conduction is mainly ionic. It increases more than one-hundredfold at the melting point for calcium and manganese silicates, and shows temperature coefficient compatible with the view that the conductivities are due to the small, relatively mobile cations, and the viscosities to the large, relatively immobile anions.

All those concerned with the application of physical chemistry to process metallurgy owe a great debt to the Faraday Society for arranging this discussion. Apart from the stimulating effect of bringing together workers in this field from many laboratories and many different countries, it has brought the criticisms and ideas of physical chemists outside this field to those who are now working in it. It is to be hoped that the discussion will also stimulate physical chemists generally to take a new interest in the fundamentals of some of these interesting high-temperature systems.

F. D. RICHARDSON

VETERINARY EDUCATION: DEVELOPMENTS AT CAMBRIDGE

By DR. JAMES T. EDWARDS

THE address before us* breathes a freshness of outlook which bestirs the imagination of those who have watched a public awakening into the need for finding a healthy solution to a problem which, since the onset of the Industrial Revolution, and even before then, has been treated in Great Britain, to its sad discredit, with sore neglect.

This problem is concerned not only with the 'doctoring of animals', the pursuit which the ordinary member of our public associates with the designation 'vet.'. That in itself, it can never be too strongly emphasized, is an art which calls forth all the skill that is born of long and close experience, all the powers of keen and careful observation, and all the moral virtues of sympathy and kindliness which the human faculties can muster. It is an art which in the course of its long history has seen its periods of great triumph and of respect in the eyes of society, and its periods of utter debasement. Its triumphant periods have been within the histories of great empires at the height of their glory—the Buddhist, the Byzantine, and the Arab; and, let us hope, the British Commonwealth, as it is now marching to higher destiny, will be added to them. One of the worst, if not the worst and most infamous, of the periods in which the art suffered degradation was that in which the Church dominated thought and conduct in the Western world—the Dark Ages. Let us insist at once that this decline in respect for the art did not owe its origin to the Christian ethic, with its dominant note of 'charity'. Compounding for it a doctrine in which the ingredients were not incompatible with persisting Mediterranean cults and contained an infusion of neo-Platonism with some tincture of Christianity, the early Church Fathers, in their wisdom, shrewdly mindful of means of fostering moral uplift among peoples as they were at that time, founded a powerful hierarchy. This hierarchy increasingly in its interest played hard on the Platonic concept of the 'soul' as a higher state of being, which was immortal, and did not pertain to the 'beasts', which in their suffering were therefore denied both pity and mercy. (This theme has been well developed recently by the eminent French scholar and experienced veterinarian Emmanuel Leclainche in his book, "Histoire de la Médecine Vétérinaire" (Toulouse: Office du Livre, rue Alsace-Lorraine, 42; 1936).) The human physicians were hence eagerly absorbed into the Church, and their learning became that of the Church, disdaining craftsmanship and the knowledge which Plato's contemporary, Aristotle, had proved could be so richly garnered for the benefit of mankind from observation on the 'brute creation'. It was not until well into the eighteenth century that craftsmanship became elevated in esteem as a branch of the healing art with the rise of the surgeons from their lowly standing of barber-surgeons. Nothing of this sort had occurred in the older civilizations where, in the Arab Empire, for example, the arts of healing, both of man and animal, were taught side by side, with equal respect, in her great universities, from Baghdad to Salamanca.

---

* Veterinary Education. An Inaugural Lecture. By Prof. W. I. B. Beveridge. Pp. 40. (Cambridge: At the University Press, 1948.) 1s. 6d. net.

After the fall of Rome, and the lapse into disuse of her magnificent road communications with the lethargy that then beset humanity, the Western world broke up into isolated communities, governed, or tyrannized, by baronial courts, the chief officials in each of which were the chamberlains, seneschals and marshals. It was to the marshals that was consigned the important office of charge of the cavalry, comprising both the management and treatment of the horses. From about the eighth century B.C., beginning in Babylonia, right up to the First World War, the use of cavalry in warfare, supplying as it did to this vital enterprise mobility and striking power, had been a main concern of rulers and States. Epidemic disease among horses, of which the chief was glanders, hampered campaigns and so encompassed gravely their existence. During the period of the Crusades, with the discovery of the art of horse-shoeing and the need for preserving cavalry on the march for long distances, a new class of menial assistants to the marshals arose who, besides acquiring proficiency in the craft of making and nailing-on (*ferrer*) iron horseshoes, were also entrusted by their masters with the more laborious duties in treatment, such as the dressing of wounds and drenching of potions. These farriers, as they came to be called, soon, in the way of human nature, supplanted their trusting, well-bred masters, the marshals, usurping as they did in France a title common to both—*maréchal-ferrant*. Doubtless among them there were to be found many observant and worthy practitioners; but, on the whole, throughout Western countries they came to be looked upon as an ignorant class recruited from the most depraved strata of the public such as the knackermen and hangmen. The brutality of their treatments, matched only by their exorbitant charges as fees, was such that, as has been well said (McFadyean, 1923), the most fortunate animals before the opening of the veterinary schools in Western Europe during the latter half of the eighteenth century were those which escaped notice by that class.

There was no dearth of good literature to be consulted, such as the remarkable symposium recorded in the "Hippiatrika" by the Byzantine hippiatrists, and emended and plagiarized in various ways throughout the Middle Ages by successive authors. Yet, strangely, the literature which was produced and obtained a large circulation, such as that of the notorious impostor, Gervase Markham (1568–1637), was of the vilest, all diseases being assigned meaningless names and little description; but, for all there was an 'infallible' cure that had been a long-guarded 'secret', and was a shameful polypharmacy calculated to assuage and exploit superstition and credulity.

An exception to this lamentable story of the West was to be seen in Spain during the days of her greatness as a world power, where the Catholic monarchs, after the expulsion of the Moors, were careful in their own interest to preserve what was best from the Arab civilization they had conquered. Among thi best was a well-educated and highly disciplined profession ministering to the domesticated animals in particular the horse, to the governing body o which profession (the *Protoalbeitariat*) they graciousl accorded their own patronage. It was not until 181 when the Spanish Cortes, meeting at Cadiz, decided in an excess of liberalism, to abolish all corporat institutions that this valuable profession becam disrupted, never again to recover its former dignit and usefulness.

Meanwhile, concern was being felt in another wa with the appallingly low state into which the healin art ministering to the animal world in the West had fallen. This concern was being felt not only by ruler and States but also by those whose interest it was t preserve the herds and flocks upon which the live and prosperity of peoples so largely depended. Fro time immemorial, recurrent waves of devastatin plagues among the domesticated animals had bee known, the most serious of these being cattle plagu (or rinderpest). As evidence of the concern of ruler may be cited that of Frederick the Great, who o return in 1767 from his Silesia campaign in the Seve Years War and fresh from witnessing the devastatio caused by cattle plague and the consequent horro suffered by the civil population, requested the Medica Faculty in Berlin to draw up plans for the openin of a veterinary school. This the professors of th Faculty did reluctantly, but added at once, almos reproachfully, that it was hoped it was not to b further expected of them to soil their hands in th carcases of beasts. The low ebb of affairs in thi respect in Britain was decried by the wise an observant physician, Sir Thomas Browne (1605-82) (Smith, F., "The Early History of Veterinar Literature and its British Development", 1, 311 1919), the author of "Religio Medici", who in hi book "Pseudodoxia Epidemica" bewailed the ignorance of the 'common farriers' to whom only recours could be had by stockowners at the time, and appeale for the raising of a new class whom he designated b a term new to the language, 'good veterinarians' Drawing on his massive classical scholarship, he ha introduced a word which was held in repute in th earlier history of Rome, signifying a cattle husbandman. The solid farming peoples from whom Rom then derived her man-power were much attached t their cattle, the older, more mature, of which (th *veterini*) they prized for their tillage, their respecte attendant being the *veterinarius*.

In Britain, concern was felt not so much by it rulers or its Government, as by the rising agricultura societies, one of which, the Odiham Agricultura Society of Hampshire, initiated the movement fo starting veterinary education in England, while, late in Scotland, the Highland and Agricultural Societ lent its powerful patronage to William Dick whe he started a school in Edinburgh in 1823.

A Board of General Officers, sitting in London i 1796, decided that the best term to use for th educated recruits drafted urgently from the Londo Veterinary College, that had been opened in 1791, fo care and treatment of cavalry and artillery horses i the Napoleonic War was 'veterinary surgeons', t distinguish them as a corps apart from the surgeon who until then had been displaying keen interest als in that work. The designation was afterward taken up enthusiastically by fellow practitione among the civil population. As the late Sir Frederic Smith (1857–1929), the meticulously accurate veter inary historian, rightly insisted, however, the designation is a misnomer, for the practitioner of the healing art among animals has ever been more of a 'physician' than a 'surgeon'. Prof. Beveridge in his address contends that the name was not "a happy choice". We may agree, to some extent, however, with Leclainche in concluding that the very lack of precise meaning in it commends it; and, further, it has a safe position in language inasmuch as most countries have introduced it into their language and so it has gained the sanction of widespread usage. The powerful sanction of usage need not, however, we can now better realize, compel ultimately refusal o employ some more explicit name when that is really needed. In Britain, for example, what was long called the Veterinary Branch of the Board (now he Ministry) of Agriculture has come to be known as the Division of Animal Health. From its foundaion in 1884, a similar great organisation in the United States has been known as the Federal Bureau of Animal Industry.

The Charter of Incorporation of Veterinary Surgeons, 1844, which gave legal recognition to the title of 'Veterinary Surgeons' as the exclusive designation of those who qualified from the veterinary colleges after passing an examination held by an elected Council of their body, was not confirmed by Statute until the passing of the Veterinary Surgeons Act, 881, when in protecting the title 'veterinary', the xclusive right to use which had been allowed to apse, a considerable body of unqualified people were brought on the register as 'Existing Practitioners'. The Act did not debar anyone, however, from undertaking veterinary practice so long as he did not use the title. In some progressive countries for a long time the veterinary profession has enjoyed the privileges of a 'closed shop', and it is one of the aims f the Veterinary Surgeons Act which has just become aw to secure the same privileges for the veterinary profession in Great Britain.

To revert to the low ebb of affairs generally preailing in Europe until well into the eighteenth century: there was, as we have seen, a widespread and periodically deeply felt need for the supply of enlightened and skilled men to control pestilence mong animals; and, as the late Sir George Newman rightly said in regard to his own calling, "pestilence as always been the opportunity of medicine". It is an opportunity, as all who have had intimate experience of the subject well know, that has to be quickly eized, for the public soon forgets once the danger is over. It has to be remembered, too, that in human medicine matters were little better, for until 1745 here was no formal medical education in England, nd thenceforward until 1782 what little that was given was imparted at private schools. Now and gain, there were forthcoming highly gifted men, without special training for the purpose, who as if by intuition divined and applied wholly appropriate measures for controlling disease. For example, in 714, Thomas Bates, surgeon to the King, by esolutely applying the model system of 'stamping-ut' contagion outlined by the Papal physician, ancisi, in 1711, succeeded in eradicating quickly attle plague from England. When about thirty ears later the disease reappeared, recurring afterwards until near the close of the century, when war revented importations of live cattle, Bates's successful experience had been forgotten or overlooked. The natural disappearance of important cattle pidemics, it may be stressed here, from Great Britain during the last part of the eighteenth century and until the beginning of the fifth decade in the nineteenth century was largely responsible for Government and organised societies losing interest for a long time in veterinary education and for its consequent falling after its inception in England in 1791 into unworthy and incompetent hands, a setback from which it never fully recovered, even to this day. James Clark, of Edinburgh, 'Farrier' to the King for Scotland, who, according to Sir Frederick Smith, may "well and truly be described as the father of Veterinary Hygiene, not only in this country but in Europe", published, in 1788, a work on the "Prevention of Disease" which is a revelation. It was doubtless the application later of the principles of ventilation to stables advocated by Clark which brought about the rapid decline of glanders and other respiratory infections in Army horses.

What is important so far as we are concerned in criticizing the work under review is—what is not emphasized in it or, for that matter, in any recent document—that the universities throughout Christendom themselves took no heed whatever of this prevailing deplorable state of affairs, for which learning and inquiry of the highest order were sorely needed. They were, on the whole, not only apathetic, but disdainful, even hostile. Several examples could be readily given if space permitted.

It was not until the twentieth century had opened that the universities awakened, and then almost everywhere in the world, to a realization that the pursuit was worthy of the exercise to the fullest of such powers as were possessed by men and women of first-rate intelligence and general education, and that they must no longer keep aloof. Of all the larger territories, Australia, at Sydney and Melbourne (though this latter school is now closed), has shown outstanding willingness to aid advance of the pursuit by its universities. But already there is much to record in the experiences of several other countries upon the association of the universities with veterinary teaching. Britain has lagged; but there have been peculiar difficulties.

How, in the meantime, veterinary education developed has been well touched upon in the address under review, and it would exceed the compass of a short article even to give a bare summary of the complicated story. The time was doubtless ripe during the latter half of the eighteenth century for it to begin, as it did, with the opening of a veterinary school at Lyons in France in 1761, and the historian can now well discern that elsewhere it made many very bad beginnings. The paramountcy of the horse, which came about with the improvement of road communications early in the nineteenth century, when the Industrial Revolution got into full swing, followed later by decline of the horse which came about early in the present century with the mechanization of road transport, have been major phenomena that have strongly impressed themselves on the trend of developments. The Agricultural Revolution, which coincided with the Industrial Revolution and largely resulted from it, is another phenomenon, the importance of which had been largely masked and ignored in veterinary developments by deflexion of interest, often entirely, to the former one of the ascendancy of the horse. What this Revolution brought in its train was a complete change in the livestock husbandry of Britain and, indeed, of almost all countries, the exceptions being those countries like India and Egypt which still employ cattle mainly as a source of motive power in agricultural operations. Otherwise, with the aggregation of large masses of people in towns which needed feeding, and with the enclosure of the commons and the abandonment of the open field system of farming, and, again, with provision for winter feeding of stock, consequent on storage of fodder and introduction of root crops, no less than the temporary absence, as already indicated, of major plagues, the cattle became transformed, largely through the genius of breeders like Robert Bakewell (1725–95) into types that were destined to meet the clamour of the towns for food, namely, meat and milk. England from being a wool- and wheat-exporting country for centuries had now new assets and new outlets, a prime asset being no longer her sheep, and wheat had to become an imported commodity of first magnitude. The invention of refrigeration, which enabled meat supplies to come from abroad, and the improvement of internal transport, so that milch cows need no longer be kept in cities, have again changed the problem confronting the veterinarian, who, paradoxically, with each succeeding change that seemed to foredoom his calling to extinction, has found himself confronted with a transformed yet ever-expanding field for enterprise.

Great triumphs lie already to his credit: in Britain, cattle plague was eradicated, after it was again introduced after a long lapse in 1865, when heed was paid at last to his counsel, so that when in 1870 it reappeared it was promptly eradicated. The legislation introduced at that time laid the foundation for State veterinary control of animal disease in Great Britain. Glanders again was eradicated in 1913; besides, nearly all the other major plagues, like bovine pleuropneumonia, rabies and sheep-pox, had by then been eliminated. Foot-and-mouth disease has been several times eradicated; but difficulties lie in preventing re-introduction with imported animal products. There remains, however, a mass of insidious disease which is very seriously limiting productivity and is sometimes a grave direct danger to man himself. Tuberculosis has become rampant among our cattle herds; but there seems no reason, particularly in the light of experience gained abroad, in the United States of America, Finland and Norway, why it should not be eradicated in time, effective legislation to bring about that result having been introduced only in 1935. Besides tuberculosis, other serious diseases affecting our dairy herds are sterility, contagious abortion, mastitis and Johne's disease, and much has been achieved already in better understanding of them and devising control. Great success has followed proper investigation, within the last three decades, of the diseases of sheep. Pig diseases are, for the most part, well in hand. In countries abroad, there have been magnificent achievements. Striking examples which may be cited are, first, in the United States, besides the suppression of tuberculosis in cattle, still earlier, following brilliant research, the eradication of Texas fever, a disease which afflicted the southern States to such an extent that economic cattle-raising had become impossible; secondly, wisely guided by the statesmanship of Botha and Smuts after the Boer War, the abundant financial resources available from the Rand were deflected without stint towards ridding the country of animal diseases which were playing havoc with its development as an agricultural country; and, in this endeavour, the successes which attended the labours of the late Sir Arnold Theiler and his disciples exceeded all anticipation.

Knowledge in nearly all departments has so far advanced within the last few decades that we can discern more clearly wherein skill of the kind that is to be derived from a sound veterinary education can be placed at the service of humanity. First, advances in nutritional science have been enormous, and they indicate plainly that a large proportion of the human race lacks adequate and proper feeding without which there must be physical deterioration inescapably predetermining mental and moral enfeeblement. The stage at which this must be rectified is at the earliest, from conception, the pregnant and nursing mother and young offspring being highly vulnerable towards inadequacy of dietary constituents comprising especially first-class protein and several other substances the richest source of which are milk, eggs, butter, cheese and other products of animal origin. A standard of living needs to be attained, therefore, at which there shall be no lack of these ingredients, and animal life consequently needs to be safely and economically propagated to meet all requirements. At present animal life in the world falls very far short of being safe or fully economic to the producers.

Secondly, what to the anthropologist or archæologist has been a minute span of human history, namely the period since the Industrial Revolution, has been fraught with enormous changes in the relationship of man to his environment, and ecologically it is a grav question whether the powers of any species, including the human species, for readjustment can withstand the strain of such a drastic change. Symptomatic probably of the strain in adjustment is a phenomenon that has come prominently into veterinary experience and, incidentally, proved pecuniarily remunerative namely, the craving of the urban classes, from the humblest to the richest, for professional attention upon their household pets—dogs and cats. This source of revenue has more than compensated the professio in England for the disappearance of the horse, and during the interval between the two world wars when Government allowed agriculture to lapse almost into a state of insolvency so that farmer could not easily pay for veterinary attention, th newly opened source must have saved the veterinar profession itself, as to a very fair proportion of it members, from dire financial straits. Some soci historians have emphasized that the migration o the rural population of England into the town after the Industrial Revolution was an unmitigate evil, in so far as childhood experience then was no passed, as it had been immemorially, in clos relationship with the numbers of other species whic the ecologist finds essential for the continuance o any species. All that, of course, awaits inquiry b workers in the several branches of the social science One cannot but be impressed in a country like Egypt where the great masses of the people—the *fellahee* —persist still in a state akin to that of pre-Industri England, with the serenity of countenance tha generally characterizes those masses, compared wit the strained, almost tormented, expressions of thos inhabitants in the few large cities who are emulatin the present urban luxury standards of the Wes The maintenance of a numerous and healthy rur population everywhere may therefore prove on prop investigation to be the highest achievement of gov statesmanship in the present troubled state of th world; and, interspersed among that population guide it, will be needed numerous veterinarian Countries like Holland, Switzerland, Hungary an the Scandinavian countries generally have perceived things already in that way and made provision for veterinary education at, State expense, out of all proportion to what was expended on the "starved and neglected" (to quote departmental committee reports) veterinary colleges in Great Britain in the past.

If one proceeds to make a proper 'job-analysis', then it will be found that to turn out veterinarians to meet the transformed and expanding situation the final objective of the necessary training is three-fold, being concerned with, first, clinical practice ('the doctoring of animals'); secondly, preventive medicine (or public control of the pestilences, grave or insidious, of the kind already mentioned); and thirdly, livestock husbandry and economy (of no less public significance than the former divisions and essential to neet the social circumstances as they are unfolding hemselves). A whole array of sciences, many of which have only just emerged as sciences in their own right, such as animal nutrition, genetics, comparative psychology, endocrinology, need to have heir proper place in the curriculum of teaching leading to the vocational objectives. Mere minor eadjustments in the traditional curriculum are out of place; but what is called for is rather a complete resetting, bearing always in mind the time in he trainee's life that ought not to be exceeded and he expense and the important question of his or her natural aptitude.

Prof. Beveridge in his address has very well pereived many of the implications of the changed ituation. The Veterinary Surgeons Act which has just been passed will give him ample freedom within the jurisdiction of a great university to develop his plans; and in all that endeavour he may be well ssured of the good wishes and goodwill of his British colleagues. That that university should have thought it to appoint a countryman of the daughter Dominion f Australia to launch its plans for a complete eterinary education on securing at last full legal anction to do so is a gesture that will appeal both o the good sense and to the finer sentiments of everyone in Great Britain. Even if space allowed, digression upon the recent history of the several ansactions which have ultimately led to the establishment of this teaching at Cambridge would be odious. However, finally, even in the shortest notice, to omit paying respectful homage to the memory of the late Sir Clifford Allbutt, regius professor of physic at Cambridge, who worked hard during his long life to achieve this end, would be ungracious, now that that end he strove so hard for has come in sight.

OBITUARIES

Prof. Ruth Benedict

The death on September 17 of Ruth Fulton Bene-ct at the comparatively early age of sixty-one deprives social anthropology of one of its most imulating writers and thinkers. Ruth Benedict was ne of the many American anthropologists who took eir early training at Columbia University under he late Franz Boas, and she remained attached to at University all her life, ending her days as the lder of a chair in the Anthropological Department. Ruth Benedict was a vigorous teacher as well as a oman of distinction and charm. In her youth she id field-work among the Zuni of New Mexico and wrote a series of monographs on them. She will, however, be chiefly remembered for her original and provocative book "Patterns of Culture", published in 1934; "Race and Racism", published during the War; and "The Chrysanthemum and the Sword", an analysis of Japanese character which appeared last year.

The fashion of her day was the conventional type of ethnographic monograph; but she early cut away from these and marched boldly out on to the frontier between psychology and anthropology. She was interested from the first in the infinite diversity of values and behaviour patterns which are found in cultures of different types. She believed that these ideals and attitudes formed a coherent whole to which she gave the title 'culture pattern'. She suggested that cultures could be grouped into types on the basis of these patterns. Cultures might be described as Apolonian, Dyonisac or Paranoiac, for example, or they could be classified as 'shame' or 'guilt' societies. The individual brought up in such societies was shaped to their dominant pattern.

Ruth Benedict never developed a systematic typology on this basis. Systematic sociology was not the bent of her mind, and her culture pattern concept could not be sufficiently rigorously defined for comparative work of this kind. On the other hand, her imaginative insight and originality suggested a new field of problems for a younger generation of anthropologists and psychologists, and her literary gifts made her work available to the general public and very much influenced educationists. She must certainly be reckoned as one of the originators of the study of culture and personality which is such a dominant trend in American anthropology to-day.

Ruth Benedict was deeply interested in contemporary problems. During the War she used her methods and concepts to provide a study of the culture patterns of the Japanese for the American Office of War Information. At the time of her death she was engaged in a study of contemporary European cultures, and particularly of their methods of child education. She visited Europe during the past summer and was present at the International Ethnological Congress at Brussels, where she impressed her fellow workers by her vigour and charm. Her death in the middle of an important piece of work will certainly be deeply regretted by anthropologists everywhere.

AUDREY I. RICHARDS

Sir George Hill, K.C.B.

GEORGE FRANCIS HILL, numismatist, and director of the British Museum during 1931–36, youngest son of Samuel John Hill and grandson of Micaiah Hill, both missionaries in India, was born at Berhampur on December 22, 1867, and educated at Blackheath School, University College School, University College, London, and Merton College, Oxford, where he obtained first classes in Classical Moderations and Literæ Humaniores, and under the influence of Prof. Percy Gardner devoted himself to the study of Greek coins. He entered the British Museum in 1893, where Barclay Head had recently published his "Historia Numorum", still the standard text-book in that subject; and edited no less than six volumes of the "Catalogue of Greek Coins". The first of these, on the "Coins of Cyprus" (1897), was followed many years later by a general history of that island, the third volume of which, published in the present year, brings the story to the Turkish conquest in 1571. Meanwhile, he did valuable service as editor of the *Journal of Hellenic Studies* and of the *Numismatic Chronicle*, edited a handbook of "Sources for Greek History", and extended his special studies to Italian coins and medals, and the practical art of die-engraving. His great "Corpus of Italian Medals before Cellini" is his monument in this field.

In 1931, Hill succeeded Sir Frederic Kenyon as director and principal librarian of the British Museum, for which he acquired the biblical "Codex Sinaiticus" from the Soviet Government, and the Eumorphopoulos collection of Oriental antiquities, and where he planted the almond trees in the forecourt. He was created K.C.B. in 1933 and retired in 1936. He took an active interest in the British Academy, the Society of Antiquaries, the Royal Commission on Historical Monuments, the Joint Archæological Committee, and the Hellenic and Numismatic Societies; and published a standard treatise on "Treasure Trove".

Hill died in London on October 18, while a memorial volume of the *Hellenic Journal* and a bibliography, compiled by his many friends, were still with the printers. JOHN L. MYRES

Mr. O. H. Latter

THE death of O. H. Latter on October 11 has removed not only a pioneer in science-teaching in schools but also one who, at the age of eighty-four, was as keen in sight and in mind and as ardent a correspondent as men sixty years his junior. His last letter in the *School Science Review*—characteristically both recalling a lecture of his Oxford days and insisting on accuracy to-day—appeared in June this year; and only two days before his death, while gardening, he shot one of his chief enemies, a grey squirrel.

Latter went as a boy to Charterhouse in 1878 and found there two science masters and no laboratory. In 1887 he took a first class in natural science at Oxford and became Berkeley fellow of Owens College, Manchester; he returned to Oxford in the following year as senior demonstrator to the Linacre professor. Next year he returned also to Keble as tutor. It was largely by chance—a very fortunate chance for science teaching—that in 1890 he returned to Charterhouse as senior science master. There he remained for thirty-six years, during ten of which he was a housemaster.

Latter's special interest was in Lepidoptera, Diptera and most particularly Hymenoptera. His paper in the *Cornhill* on wasps is typical of his gifts for observation and sympathetic exposition. But no branch of natural history escaped him. He contributed to various scientific journals papers on shell-fish, the rabbit, puss-moth, cuckoo's eggs, an odd contortion in dog's mercury, and as a 'holiday task in his seventieth year (with H. Eltringham) on the scent mechanism of the male *Euplœa*. No living thing seemed to him to have been so well studied that nothing new could be observed about it, as witness his papers on the breathing of tadpoles (1923) and the dispersal of burdock (1941).

But Latter was far more than an observer, a writer of broad and lucid text-books and a teacher, great as is the debt his pupils owe to him and continue to acknowledge. He was a founder of what was then the 'Public Schools' Science Masters' Association' and his profound belief in the value of science (and especially biology) as an essential, and not merely a vocational, element in education has had an influence far beyond the public schools. Addresses of his exis on this, his favourite, subject to the British Association, the Association of Preparatory Schoolmasters and the Rotary Club of Colombo; and apart from this wider appeal his public spirit made him for many years the most valued chairman of Godalming Higher Education and Corporation Museum Committees and of the governors of Godalming County School. Fifty-eight years of meteorological observations have ended with his passing: his immense contribution to education remains. J. C. THOMSON

WE regret to announce the following deaths:

Prof. Johan Hjort, For.Mem.R.S., known for his sea-fisheries investigations, on October 7, aged seventy-nine.

Prof. Gustave Roussy, *académicien libre* of the Paris Academy of Sciences, formerly rector of the Sorbonne and director of the Cancer Institute of the Faculty of Medicine, Paris, on September 30, aged seventy-three.

Dr. J. H. M. Wedderburn, F.R.S., professor of mathematics in Princeton University, aged sixty-six.

Dr. C. M. Wenyon, C.M.G., F.R.S., formerl director-in-chief, Wellcome Research Institution, o October 24.

NEWS and VIEWS

Dr. Lise Meitner

WHEN, on November 7, Dr. Lise Meitner celebrates her seventieth birthday, her many friends will offer her their warmest congratulations and respectful admiration on a life of great activity, during which she has maintained the highest reputation for experimental discoveries in radioactivity and nuclear physics. Dr. Meitner studied under Boltzmann in Vienna. Moving to Berlin, she was for a time '*Assistent*' to Planck. She then joined Otto Hahn and thus began a long and rich collaboration, ended only by her flight from the Nazi regime. Her investigations during this period of about thirty years are so many and so varied that only a few can be mentioned here. An early joint paper on the absorption of β-rays was followed by the discovery, wit von Baeyer, of homogeneous groups in the β-ra emission from radioactive bodies. This opened up new field, to which she returned again and again i subsequent years, taking a leading part in th elucidation of β- and γ-ray spectra and in the stud of the properties of β- and γ-rays. To the earlie period of collaboration belongs also the discovery protoactinium in 1918. In later years she worke with Hahn, and also with Strassmann, on th neutron-induced radioactivity of uranium. Aft Hahn and Strassmann had discovered the presence active barium in irradiated uranium, and thereb established the division of the uranium nucleus, D Meitner and her nephew O. R. Frisch gave, in letter in *Nature* in March 1939, the first physic picture of the fission process, introducing the term 'fission' and making an estimate of the energy liberation. Using the method of recoil, which she and Hahn had applied so effectively in the early days of radioactivity, she was later able to show that the bodies previously called 'transuranic' did, in fact, originate by fission. Since 1939, Dr. Meitner has worked in Stockholm, where she now directs a small but active laboratory. Enjoying good health and abundant energy she can, while looking back on a life full of high achievement, also look forward to further years of happiness and success.

Nobel Prize for Medicine : Dr. Paul Müller

The award of the Nobel Prize for Medicine for 1948 has been made to Dr. Paul Müller for his discovery of the effects as an insecticide of D.D.T. Drs. P. Läuger, P. Müller and H. Martin were the leaders of an intensive research for insecticidal chemicals in the Basle laboratories of J. R. Geigy, S.A., which extended more than twenty years. The researches were directed originally towards the discovery of moth-proofing agents to be incorporated in fabrics. It was in the section of research entrusted to Paul Müller that D.D.T. was actually synthesized and its contact insecticidal properties discovered. It seems to have been in the course of field trials that its remarkable effectiveness against the Colorado beetle was noticed. It was soon found to be equally toxic to the louse and the mosquito. The material was brought to the notice of medical entomologists in Great Britain and the United States at a critical moment in the War when the supplies of pyrethrum were rapidly falling short of the demand. Soon it was being produced in very large quantities on both sides of the Atlantic. It proved of enormous value in combating typhus and malaria during the War, and now it is being employed with success in campaigns for the complete eradication of malaria from island areas. It is an equally valuable weapon in agricultural entomology and has provided a great stimulus to the search for yet other insecticides.

Dr. G. M. Vevers

Dr. G. M. Vevers, superintendent of the Zoological Society of London, will be retiring for medical reasons at the end of the year. He received his medical education at St. Thomas's Hospital, London, and served in the First World War as a captain in the R.A.M.C. After demobilization he became assistant o Prof. R. T. Leiper, in the Department of Helminthology of the London School of Tropical Medicine, and was awarded a Beit Medical Fellowship for Medical Research in parasitology. The same year he was also appointed honorary parasitologist to the Zoological Society and spent much of his time in the Society's prosectorium. In 1921 he went to British Guiana on a Colonial Office inquiry into filariasis. In 1923 Dr. Vevers was appointed superintendent of the Zoological Society in succession to the late R. I. Pocock. He introduced the application of the general principles of hygiene to wild animals in captivity, paying particular attention to the helminthic infections which used to be such a frequent ause of death in newly imported animals. He also introduced improvements in diet and housing, resulting in a reduction of the incidence of dietetic diseases and epidemics such as tuberculosis. He was also responsible for carrying out the extensive building programme at the Zoological Gardens, Regent's Park, following the First World War.

Dr. Vevers was closely associated with the late Sir Peter Chalmers Mitchell in the formation and development of Whipsnade Zoological Park, in which he took a very special interest. He also designed the layout of the Dudley Zoological Gardens, and since the Second World War has been engaged in the reconstruction and rehabilitation of the Zoo at Regent's Park. He is the author of numerous papers on helminthology and the keeping and breeding of animals in captivity; also children's books and other books on general natural history, and has been a regular broadcaster in the B.B.C. Children's Hour and other programmes. He was elected an honorary fellow of the Royal College of Surgeons in 1946; and has been awarded the Silver Medal of the Zoological Society of London, and the Gold Medal of the Zoological Society of Glasgow and West of Scotland. After his retirement Dr. Vevers will continue to reside at Whipsnade, and will be available for consultation by the Society in an advisory capacity.

Botany at Rothamsted : Dr. Winifred E. Brenchley

On her retirement from the post of head of the Botany Department, Rothamsted Experimental Station, on October 1, Dr. Winifred E. Brenchley had completed forty-two years of service there. She went to Rothamsted in 1906 as the holder of a Gilchrist Studentship of the University of London, and in the following year was appointed to the permanent staff. Dr. Brenchley was the first woman member of the staff, and it says much for her personality and for the quality of her work that the appointment was an immediate success and paved the way for many other women to undertake research in agricultural science at Rothamsted. Dr. Brenchley was a pioneer in the study of the effects of micronutrient elements on plant growth, and is an acknowledged authority in this field. Before the importance of elements such as boron, copper and manganese in plant nutrition was fully appreciated, she began a long series of solution-culture studies on elements other than the ten known to be essential. Her monograph "Inorganic Plant Poisons and Stimulants", published in 1914, described her own results and provided a valuable critical summary of the scattered information then existing on the subject. The investigation of the effects of boron made afterwards is perhaps the best-known work from her laboratory. Dr. Brenchley's other chief interests have been in the ecology of weeds, and in the changes with time in the flora of the permanent Park Grass plots at Rothamsted. The results of her earlier studies on these plots provided material for her book "Manuring of Grassland for Hay", published in 1924. Dr. Brenchley has played a very active part in the social life of Rothamsted, and in recognition of her long-continued interest in the welfare of all members of the staff, a presentation was made to her at a party held on October 22, attended by many of her past and present colleagues. Dr. Brenchley is to continue her research work at Rothamsted on a part-time basis. Her successor as head of the Botany Department is Dr. D. J. Watson, formerly in charge of the Crop Physiology Section, which has now been merged with the Botany Department.

Indian Archæology at the University of London

On October 28, at the Institute of Archæology, London, Prof. K. deB. Codrington, the newly appointed professor of Indian archæology, gave an inaugural lecture entitled "The Place of Archæology in Indian Studies". The High Commissioner for India, Mr. Krishna Menon, who took the chair, said that the creation of such a chair was very welcome and he hoped that it would lead to exchanges of scholars on both sides. He welcomed the appointment of Prof. Codrington, whose second home was India. In his lecture, Prof. Codrington stressed the educational value of the study of archæology, and the need of close collaboration between all who are interested in the study of India. Outlining the relations of the earliest city culture in India with north and south Persia, he went on to describe the intrusion of the neolithic tanged-adze culture of South-East Asia with reference to the first appearance of the Aryans in India. The chair of Indian archæology in the University of London is held jointly at the Institute of Archæology and the School of Oriental Studies.

Food and Agriculture Organisation

The fourth annual conference of the Food and Agriculture Organisation of the United Nations will open in Washington on November 15. The conference will review the world food situation and the technical activities of the Food and Agriculture Organisation. It will also consider major constitutional, administrative and financial issues, particularly the budget for the next financial year. The United Kingdom delegation will be led by Mr. Tom Williams, Minister of Agriculture and Fisheries; the alternate leader is Mr. R. H. Franklin, deputy secretary in the Ministry of Agriculture and Fisheries. Among other members of the delegation will be Sir Ralph Enfield (chief economic adviser) and Mr. A. T. A. Dobson (fisheries adviser), both of the Ministry of Agriculture and Fisheries; Dr. N. C. Wright (chief scientific adviser), of the Ministry of Food; Sir Gerard Clauson, assistant under-secretary of State in the Colonial Office; Mr. P. N. R. Butcher, assistant secretary in the Ministry of Health; Mr. A. N. Duckham, agricultural attaché to the British Embassy; and Mr. G. R. Oake, head of the British Supply Office (Food) in Washington. In addition, Mr. James Turner, president of the National Farmers Union, and Mr. E. G. Gooch, president of the National Union of Agricultural Workers, will serve as advisers to the delegation.

Biological Service in Great Britain

Mr. Herbert Morrison, Lord President of the Council, announced in the House of Commons on November 1 that Capt. Cyril Diver has been appointed head of the biological service which is to be formed for the conservation of the fauna and flora of Great Britain, including Nature reserves. The London office of the service is at Thorney House, Smith Square, S.W.1.

Society of Chemical Industry: Fine Chemicals Group

The Fine Chemicals Group of the Society of Chemical Industry has for its objects "The discussion of fine chemicals especially such as are of therapeutic or biological interest". The Group held its inaugural meeting at the Royal Institution on October 5, with Sir Jack Drummond, chairman of the Group, presiding. Prof. J. H. Burn, professor of pharmacology, University of Oxford, delivered the inaugural address and reviewed much of the important work that has been done in the production of fine chemicals for medicinal use. He recalled the lapse of time between the discovery of penicillin in 1929 and its use in 1941, and suggested that, but for the recognition of the curative value of sulphonamides, it is possible that the use of penicillin might have been held up indefinitely owing to the false notion that "an antibacterial agent for use in man is an impossibility". Prof. Burn referred particularly to the work in the fields of tuberculosis and cancerous growths, of which the latter is still, in his opinion, the outstanding unsolved problem; it is one thing to deal with bacteria in the blood and extracellular fluid, but quite another thing when the bacterial agents are inside the cell or even in the nucleus. Much knowledge is to be gained from the classical work of Dale and Laidlaw with Carr, Barger and Ewins on adrenaline (and sympathomimetic amines), histamine and acetylcholine. It is increasingly obvious that the effect of chemical substances in the body is to modify or interfere with the action of these three compounds. This matter is of great importance in the study of anæsthetics, and it would be worth while to promote research in this direction. In the general problems of research, Prof. Burn felt that the university worker ought to pass on more of his knowledge to the industrial laboratories, and the industrial men of science must take 'refresher' courses in the academic laboratories to keep abreast of new techniques. The crying need of to-day is not for more fundamental knowledge but more application of the present existing knowledge. In conjunction with this, Prof. Burn expressed the opinion that the value of elaborating quantitative methods for the estimation of biological properties is indisputable. This work has been criticized as not leading to any fundamental discovery; but since 1926 chemical work has been much facilitated by the introduction of biological standards, and the Pharmaceutical Society has made a wise decision in establishing a laboratory for the study of biological standardization.

Cultural Geography of the Tarascan Area, Mexico

Pub. No. 7 of the Institute of Social Anthropology, Smithsonian Institution, Washington, by Robert C. West, may be specially welcomed because it deals with a population in its environment in western Mexico, and takes note of physical features, climate, agriculture, handicrafts, houses and settlements and material culture generally. The geognostic map is an interesting key to the environment and so are the maps, admittedly based on inadequate data none too reliable, of climatic features, especially the frequency of frost on the highlands. Tarascan was an indigenous language of pre-Spanish days; the conquerors misused the natives in mines and elsewhere, missionarie and others 'hispanized' large numbers of the remainde on great *estancias* (stock-raising farms) and *hacienda* (crop farms); so the old language lingers only in th poorer areas which Europeans did not wish to occupy The recession of Tarascan speech is traced in map for different periods. Wheat and barley were cultivated soon after the Spanish Conquest in order to pa the tribute demanded by the authorities, and Arabi modes of irrigation also came in. Each community had owned surrounding lands in which the chie apportioned the right of user among the villagers Since the mid-nineteenth century, individual ownership has developed; but vestiges remain, and in som pueblos a head-of-family may have 2–4 hectare allotted *sine die* provided he does not leave th land untilled for more than two successive years He may sell his right-of-user, but only to anothe member of the pueblo. The woodland is, at least in theory, communal property. The gradations from indigenous to more or less European tradition give pages of special interest to this book.

High-Vacuum Equipment

PARTICULARS have recently been received from Messrs. W. Edwards and Co. (London), Ltd., Kangley Bridge Road, London, S.E.26, of several new devices which they manufacture for use with pumps and vacuum equipment. These include controllable leaks for the continuous admission of small quantities of gas to a vacuum system. A dial allows any particular setting of the valve to be noted and repeated. The other equipment consists of various combinations of bellows and micro-switches to form pressure-controlled relays capable of operating a half-horse-power A.C. motor. One version can be used to switch off power supplies, or start a motor, when the pressure in a vacuum system reaches any pre-determined value between 15 and 500 mm. of mercury. Another application is as a safety device which comes into play when the rate of flow of liquid in a tube falls outside chosen limits. This instrument is also supplied in a form which indicates the rate of flow on a dial. No doubt many applications of these units will be found in apparatus which has to run for long periods without attention.

Colonial Services: Recent Appointments

THE following appointments in the Colonial Services have been announced: J. S. Campbell, agricultural officer, Nigeria; H. D. Matheson, agricultural officer, Federation of Malaya; D. J. Parsons, agricultural officer, Uganda; J. B. D. Robinson, chemist, Department of Science and Agriculture, Barbados; J. W. F. Chapman, assistant conservator of forests, Nigeria; D. A. Francis, assistant conservator of forests, Gold Coast; F. W. Binge, geologist, Kenya; T. C. James, geologist, Tanganyika; D. L. Searle, geologist, Kenya; R. B. Smith, agricultural officer, Trinidad; M. E. R. Taylor, assistant conservator of forests, British Guiana; J. H. Wheelan, assistant conservator of forests, Gold Coast; H. Gillman (agricultural officer, Tanganyika), senior agricultural officer, Tanganyika; R. Johns (agricultural adviser to the comptroller of development and welfare, West Indies), deputy director of agriculture (regional), Nigeria; R. W. R. Miller (agricultural officer, Federation of Malaya), director of agriculture, Sarawak; A. Smith (rural education officer, Gold Coast), principal agricultural education officer, Gold Coast; F. E. Hughes (senior assistant conservator of forests, Gold Coast), conervator of forests, Gold Coast.

University of London

THE title of professor emeritus in the University of London has been conferred on the following: Sir Alexander Fleming, professor of bacteriology in St. Mary's Hospital Medical School since 1928; Sir Francis Fraser, professor of medicine and physician n St. Bartholomew's Hospital Medical College during 920–34 and professor of medicine in the British Postgraduate Medical School during 1934–46; Prof. H. Gordon Jackson, professor of zoology in Birkbeck College since 1928, and master of the College; and Prof. C. H. Lobban, formerly head of the Department f Civil and Mechanical Engineering and professor of civil engineering in King's College during 1935–46.

The following doctorates have been conferred: D.Sc. on Elsie M. Widdowson (Imperial College); D.Sc.(Eng.) on Hugh Ford (Imperial College), H. C. H. Gurney and Harry Walker (external students).

Royal Society of Edinburgh: Officers for 1948–49

AT a statutory meeting of the Royal Society of Edinburgh, held on October 25, the following officers and members of council were elected: *President:* Sir William Wright Smith; *Vice-Presidents:* Prof. W. M. H. Greaves, Prof. James P. Kendall, Sir Ernest Wedderburn, Prof. A. C. Aitken, Prof. E. P. Cathcart, Sir Alexander Gray; *General Secretary:* Dr. J. E. Richey; *Secretaries to Ordinary Meetings:* Prof. E. T. Copson, Prof. Arthur Holmes; *Treasurer:* Mr. Andrew White Young; *Curator of Library and Museum:* Dr. John E. Mackenzie; *Ordinary Members of Council:* Prof. A. D. Hobson, Prof. W. O. Kermack, Dr. John Weir, Prof. J. H. Gaddum, Prof. G. D. Preston, Prof. S. J. Watson, Mr. R. Ll. Gwilt, Prof. J. N. Davidson, Mr. Edmund G. Dymond, Mr. Charles W. Parsons, Prof. R. W. Wheldon, Prof. E. M. Wright.

Institute for the Study of Animal Behaviour

AT the annual general meeting of the Institute for the Study of Animal Behaviour, held on October 10 in the rooms of the Linnean Society, Dr. W. H. Thorpe, of the Department of Zoology, Cambridge, was elected president in succession to Prof. Edward Hindle. Dr. Thorpe, who is a leading British worker in the field of animal behaviour, is a member of the editorial board of *Behaviour*, the new international journal devoted to this subject. Dr. P. H. T. Hartley, of the Edward Grey Institute, Oxford, was elected joint honorary secretary with Prof. Alastair N. Worden, while Mr. James Fisher, a former honorary secretary, was elected honorary treasurer. The following were elected to serve as members of Council: Mr. R. J. Bartlett (London), Dr. J. T. Edwards (London), Dr. John Hammond (Cambridge), Prof. A. C. Hardy (Oxford), Prof. Edward Hindle (London), Prof. Julian Huxley (Unesco), Dr. E. S. Russell (Hastings), Dr. Arthur Walton (Cambridge) and Dr. C. W. M. Whitty (Oxford).

Announcements

A DISCUSSION on "The Theory and Practice of New Techniques in Separation and Purification", to be held by the Chemical Society on November 25, has been arranged by Dr. R. P. Linstead. There will be two sessions: "Chromatography and Partition Chromatography", at 2.30; "Ion Exchange", at 7.

A COMPLIMENTARY dinner was given on October 22 to Prof. John Read by the members of the Chemical Society of the University of St. Andrews to mark the celebration of his silver jubilee as professor of chemistry in the University, to which he came in 1923 from the chair of organic chemistry at the University of Sydney. Mr. A. R. Battersby, president of the Society, presided over a representative gathering, which included Sir James Irvine, principal of the University and a former occupant of the chair of chemistry.

ERRATUM.—In *Nature* of October 30, p. 690, under "The Night Sky in November", line 8, for "easterly" read "westerly".

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Life-Span of Red and White Blood Corpuscles of the Hen

In a former communication[1], a method of determining the life-cycle of nucleated erythrocytes was described. The method is based on the fact that radiophosphorus incorporated into desoxyribosenucleic acid molecules during the formation of the red corpuscles in the marrow of the hen remains in the erythrocytes throughout their life-time. If labelled sodium phosphate is administered repeatedly to a hen with the aim of keeping the plasma activity at a constant level, the specific activity of the desoxyribosenucleic acid phosphorus extracted from the erythrocytes is found to increase with time according to a linear curve and to reach the level of the specific activity of the inorganic phosphorus of the blood plasma after the lapse of 33 days. Thus, after that date, we find only such red corpuscles in the circulation as were formed during the experiment. As, according to these experiments, about five days elapse before the labelled corpuscles are released into the circulation, the life-span of the red corpuscles works out to be $33 - 5 = 28$ days.

An alternative method of the determination of the life-span of the red corpuscles is the following (cf. Shemin and Rittenberg's[2] experiments, in which glycine containing nitrogen-15 was administered). Phosphorus-32 is injected only at the start of the experiment. During the first day, when the activity-level of the marrow is very high, strongly active erythrocytes are formed. During the days after the injection, the activity of the plasma, and correspondingly that of the marrow, is rapidly declining, and the erythrocytes formed at later dates show a much smaller activity. The specific activity of desoxyribosenucleic acid phosphorus isolated from erythrocytes is nil during the first two days; but it rapidly increases during the fourth and even the fifth day after the injection. This indicates that the main part of the strongly active corpuscles is released into the circulation at that date. Later, the activity increases, but only slightly, as erythrocytes formed with smaller activity reach the circulation. This increase continues until the strongly active corpuscles formed during the first day of the experiment reach their life-span and are removed from the circulation. From this point onwards, the activity rapidly decreases so long as these cells are being broken down.

From the data obtained for the specific activities of plasma inorganic phosphorus and desoxyribosenucleic acid phosphorus of the corpuscles, and by making use of the considerations put forward by Shemin and Rittenberg[2], it is possible to calculate the percentage of the corpuscles present in the circulation which is formed during the first day of the experiment. (Details of such a calculation will be published shortly elsewhere.) Fig. 1 shows the results of an experiment aiming at the determination of the life-cycle of the red corpuscles. The horizontal part of the curve between 6 and 32 days indicates clearly that the number of labelled atoms, and hence the number of labelled corpuscles, present in the circulation does not change within that interval of time. The sudden decrease in the number of labelled corpuscles at about 35 days is thus to be interpreted as due to the disappearance not of the labelled phosphorus atoms alone, but of the total corpuscles. In this experiment, the release of the labelled corpuscles into the circulation was found to take place after the lapse of three days, in contrast to five days in the first method described, mainly due to a more refined method of measurement. Correspondingly, the mean life-span of the erythrocytes is about $35 - 3 = 32$ days.

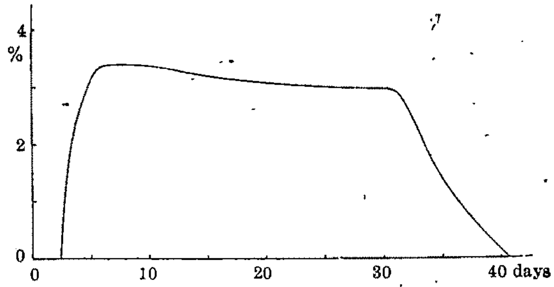

Fig. 1. Percentage of hen *red* cells formed during the first day of the experiment which is present in the blood stream at the time indicated on the x-axis

Though the white corpuscles are a mixture of different corpuscle types, it seemed to be of interest to determine the life-span of this mixture, making use of the second method. 60 μC. radioactive sodium phosphate was injected into a hen and blood samples were secured at suitable intervals. The leucocytes were isolated by the method of Butler and Cushman[3] and their desoxyribosenucleic acid phosphorus was extracted by Schmidt and Thannhauser's method[4]. The percentage of the white corpuscles formed during the first day and present in the circulation at subsequent dates is seen in Fig. 2. Should white corpuscles show a similar behaviour with respect to their life-cycle as do red corpuscles, we might expect the curve to have a horizontal part. This, however, is not the case. This fact is due partly to the inhomogeneity of the mixture of white corpuscles and partly to the comparatively short life-time of the corpuscles; furthermore, there is a large statistical variation in the life-times of single white corpuscles. The curve indicates that at the most 10 per cent of the white corpuscles have a life-span of more than eight days.

Objections may be raised to this explanation and one might be tempted to interpret the results obtained by assuming that the white corpuscles do not preserve their 'label', and that we are confronted not with a change in the number of labelled white corpuscles, but with a turnover phenomenon. This can be shown, however, not to be the case. It is found that if the formation of new white corpuscles is stopped by irradiating the hen with 2,000 r., and phosphorus-32 is then administered, no labelled desoxyribosenucleic

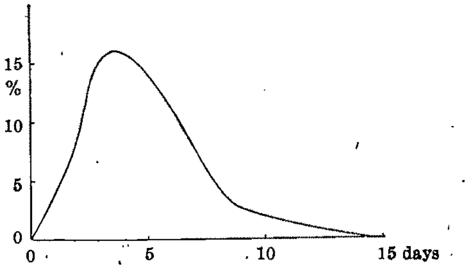

Fig. 2. Percentage of hen *white* cells formed during the first day of the experiment which is present in the blood stream at the time indicated on the x-axis

acid is formed in the leucocytes present in the circulation. This lack of formation of labelled nucleic acid can scarcely be a consequence of the effect of X-rays on the turnover rate, because a dose of 2,000 r. diminishes, but does not entirely stop, the renewal of desoxyribosenucleic acid in all types of tissue investigated[5]; it must be interpreted as a lack of formation of new white corpuscles. The turnover of desoxyribosenucleic acid, present in the white corpuscles is thus negligible.

I wish to express my most cordial thanks to Prof. N. Bohr for numerous facilities put at my disposal, and to Prof. G. Hevesy for his kind interest and many helpful suggestions throughout the work.

Introduction of Radioactive Tracers into Antisera

It has been found possible to introduce radioiodine into the globulin molecule of an antiserum without seriously impairing the agglutinating power of the serum.

The globulin fraction of a *Proteus vulgaris* rabbit antiserum was prepared by two successive precipitations with a 22 per cent concentration of sodium sulphate, and dissolved in $M/15$ phosphate buffer of pH 7. It was then treated with an aqueous iodine solution (0·1 mgm/ml.) containing also some 8-day radioiodine. Reaction is complete in a few minutes, approximately 20 per cent of the iodine being substituted into the globulin. The remainder, now present as iodide, was removed by dialysis.

A solution containing 5 mgm. of the iodinated antiserum globulin in 70 ml. of pH 7 phosphate buffer was mixed with 5 ml. of normal serum and sufficient *Proteus* suspension to remove all the agglutinins. After standing for one hour at 56° C., the agglutinated bacteria were filtered out, washed, and their radioactivity determined. The accompanying table is typical of the results obtained.

Iodine atoms (n) per antiserum globulin molecule (mean), assuming mol. wt. globulin 156,000	Percentage of total activity precipitated
1·0	8·1
2·3	8·1
3·1	9·3
7·7	5·7

A control experiment with normal rabbit globulin gave only about one per cent of precipitable activity, which may have been due to naturally occurring agglutinins in the serum.

With increase of the iodine content above 10 atoms per molecule, the agglutinating titre and percentage of precipitable activity of the globulin showed a marked decrease. The iodine probably becomes substituted into the tyrosine residues, of which there are about 58 per molecule.

If the number of iodine atoms, n, as defined in the above table is small compared with 58, the probability of a globulin molecule containing m iodine atoms will be:

$$\frac{n^m}{m!} \cdot \exp - n.$$

Consequently, for $n = 1$, 36·8 per cent of the globulin molecules will contain no iodine; but for $n = 7·7$, only 0·05 per cent will contain no iodine. Since, however, over this range of n the agglutinating titre showed little alteration, it follows that slightly iodinated antiserum globulin has substantially the same agglutinating properties as the untreated antiserum globulin.

It should be possible to use this technique for the standardization of a considerable variety of antisera.

I wish to thank Drs. R. F. Menzies and H. Bensted, who prepared the antisera. Acknowledgment is made to the Director, Atomic Energy Research Establishment, for permission to publish these results.

Succinic Acid in the Blood of the Larva of *Gastrophilus intestinalis*

During the course of biochemical investigations on the parasitic larvæ of the fly *Gastrophilus intestinalis*, advantage was taken of the ease with which the hæmoglobin-containing 'tracheal organ' cells[1] and the hæmolymph which surrounds them could be obtained in order to study the interrelationship between the two *in vitro*. For this purpose an investigation of the respiratory metabolism of the tracheal organ was undertaken, employing standard manometric methods.

The oxygen uptake of tracheal cells in either phosphate buffer or a specially prepared '*Gastrophilus* Ringer' solution was small; but it was increased up to nine times in presence of the insect's own hæmolymph. Analyses of fructose, glucose, lactate, pyruvate, citrate and succinate having been made on the blood[2,3], the effect of these substances, and of fumarate and butyrate, on the oxygen consumption of the tracheal cells suspended in phosphate buffer was determined. Only with succinate was there an increase in oxygen uptake comparable with that found when the hæmolymph was the suspension medium. Evidence that the factor present in the hæmolymph responsible for this increase is indeed succinate was obtained as follows.

Preliminary experiments showed that the active material was dialysable and could be extracted by ether at an acid pH. Accordingly, the blood from some 1,200 third-instar *Gastrophilus* larvæ was dialysed against three changes of distilled water. The combined external fluid was acidified to pH 2, reduced in bulk by evaporation to 50 c.c., and continuously extracted with ether for ten hours. At this stage the aqueous phase was devoid of activity when tested with tracheal organ cells. The ether extract was then itself extracted three times with equal volumes of water, and the combined aqueous extract washed with a quarter of its volume of ether to remove easily ether-soluble substances. The aqueous solution was now evaporated to dryness, the solid residue taken up in 150 c.c. of ether and evaporated down to 5 c.c. The resulting crystals were filtered off, washed with ether and dried *in vacuo*. The yield was about 400 mgm. The crystals were monoclinic, and had a melting point (uncorrected) of 186–190° (m.p. of succinic acid, 184°). The silver salt of the acid, prepared according to Mrs. Needham's method[4], contained 62 per cent silver (theoretical : 65 per cent). When tested manometrically with a succinoxidase preparation from either pig heart or tracheal cells, the crystalline material was shown to be 91 per cent pure succinic acid.

By the same method succinate was also determined in *Gastrophilus* hæmolymph after deproteinization and ether extraction. The concentration varied from 128 to 404 mgm. per cent. The amount is already high in the half-grown second instar (the earliest stage at which it is practicable to collect hæmolymph), and appears to increase just prior to the second moult, to be followed by a decrease in the early third instar. These changes are summarized below.

Half-grown 2nd instar	2nd instar just prior to moulting	Early 3rd instar	Fully grown 3rd instar
279 mgm. %	351 mgm. %	203 mgm. %	242 mgm. %

To test whether succinic acid might have been formed during dialysis by continuous breakdown—enzymatic or otherwise—from some precursor, the hæmolymph was collected directly into 10 per cent metaphosphoric acid and the silver salt prepared. The yield from some 100 c.c. of blood was 230 mgm. of succinic acid, which shows that succinate is a normal constituent of the blood and not a breakdown product.

Pryor, Russell and Todd[5] reported that succinic acid was obtained from *Lucilia* pupæ, and this suggests that high concentrations of succinate may also be found in other species of insects. At present, however, any indication as to the origin or function of the succinate in the blood must await further study.

We should like to thank Prof. D. Keilin for suggesting this line of work, for his continued interest and advice, and the Agricultural Research Council for a research grant to one of us (L. L.).

Staphylococcal Coagulation and Fibrinolysis

Smith and Hale[1] were the first to point out that coagulation by staphylococci takes place in two stages. First, the bacterial product is converted to a thrombin-like agent by an activator substance found in plasma. This thrombin-like agent then produces fibrin. Gerheim, Ferguson and Travis[2], and Kaplan and Spink[3] have pointed out that the activator substance is associated with the albumin fraction in ammonium sulphate fractionation, while the latter workers showed that in alcoholic fractionation the activator appears to be associated with the alpha and beta globulins. Kaplan and Spink also have made an important contribution in their studies on the inhibition of the staphylocoagulase reaction.

Staphylococcal fibrinolysis in the past has either been ignored or explained on the basis that staphylocoagulase is a proteolytic ferment[4]. Lack[5], working in Britain, and Gerheim *et al.*[6,7] in the United States, have shown that staphylococcal coagulation and fibrinolysis are distinct phenomena. They are in agreement that staphylococci produce a kinase for the proenzyme, plasminogen (profibrinolysin), just as streptococci do. This kinase has been designated staphylokinase.

Gerheim *et al.*[7], in a series of heat-lability studies, have shown that heating for two hours at 75° C. completely destroys the coagulation precursor (prostaphylocoagulase), while there is little change in the staphylokinase reactivity.

Excretion of D-Pyrrolidone Carboxylic Acid by Rat and Dog Fed with Tumour Proteins

There has been much controversy about our claim[1] that D-glutamic acid is a constituent of tumour proteins. Many authors were unable to confirm our results, and in their opinion the D-form which we isolated from malignant tumours was formed by partial racemization *in vitro* during the hydrolysis with hydrochloric acid. An explanation of these contradictory results will be given in future publications. Here we wish to record further evidence for the correctness of our views.

In 1940 we reported[2] that the normal dog was unable to digest rabbit tumours (Brown – Pearce) in the same way as common meat. The Neuberg[3] precipitate of the urine contained a peptide fraction which on hydrolysis yielded glutamic acid with 17 per cent D-form. From the peptide fractions of the fæces we isolated glutamic acid with 53 and 57 per cent D-form respectively, that is, with a surplus of the unusual antipode. So far as we know, these experiments have never been repeated in other laboratories. In connexion with some new facts mentioned below, it was desirable to repeat the experiments in our laboratory for a third time. A dog was fed for four days with cooked rat tumours (benzpyrene). The isolation of the peptide fraction of the fæces was carried out in the same way as described previously. In the new case the isolated glutamic acid contained 33 per cent D-form ; the lower value is in good agreement with our general experience that the rat tumours (benzpyrene) produce on acid hydrolysis only about half as much D-glutamic acid as the very malignant Brown – Pearce tumours.

In 1944, S. Ratner[4] reported the isolation of optically pure D-pyrrolidone carboxylic acid from the urine of rats after feeding a normal stock diet with the addition of DL-glutamic acid. The conversion is probably enzymatic. It seemed to us that, in our feeding experiments with tumour proteins, a part of the D-glutamic acid might have been split off and converted to D-pyrrolidone carboxylic acid. As this cyclic derivative is not precipitated by Neuberg's reagent, we would not have found it in our earlier experiments. The collected urine of the dog was adjusted to *p*H 2 (with sulphuric acid), filtered and continuously extracted for forty-eight hours with ethyl acetate, the temperature of the aqueous layer being 15° C. throughout this period. The oily residue obtained after the evaporation of the ethyl acetate was treated in the same manner as described by S. Ratner[4]. We finally obtained a colourless crystalline product which was identified by the melting point (alone and in mixture), the optical rotation ($[\alpha]_D = + 11{\cdot}2°$) and the analyses as the pure D-form of pyrrolidone carboxylic acid. We estimate that about 10 per cent of the D-glutamic acid of the tumour originally present is excreted in this way.

As a control, the same dog was fed with beef and the urine extracted with ethyl acetate. In this case deuterio-D-pyrrolidone carboxylic acid (5·30 atomic per cent deuterium) was added to the extract. The recovered tracer substance showed no depression of the isotope contents. This is in complete agreement with the results of S. Ratner[4]; further, D. Shemin and D. Rittenberg[5] demonstrated, with deuterium and nitrogen-15 as tracers, that no D-glutamic acid is formed in the organism of the vitamin B_2-deficient rat, a conclusion which is reasonably applied also to the normal animal.

In another experiment, tumour proteins of rats (benzpyrene) were fed to normal male rats. Here again we isolated D-pyrrolidone carboxylic acid from the urine; in this case the final purification was carried out by chromatographic fractionation (Al_2O_3 Brockmann II–III; alcohol as solvent). The optical purity of the cyclic compound was demonstrated by the conversion to D-glutamic acid ($[\alpha]_D = - 31{\cdot}5°$).

The excretion of an optically pure derivative of D-glutamic acid after the enzymatic 'digestion' of tumour proteins is not compatible with the current view that the D-form which we isolate after acid hydrolysis of tumour proteins is an artefact. Moreover, an important consequence for future experiments may be pointed out. We know from experiments, mainly unpublished, with labelled amino-acids that a small part of fed or injected D-glutamic acid is incorporated in the tumour proteins. If the labelled molecules of D-glutamic acid are displacing the 'intrinsic' ones, a decrease of the isotope content of the excreted D-pyrrolidone carboxylic acid should be demonstrable. However, it is not yet clear whether the 'extrinsic' D-glutamic acid is really displacing intrinsic D-glutamic acid, or whether it is being additionally incorporated. Another premise is a favourable ratio between the 'extrinsic' and the intrinsic' D-glutamic acid. In any event, the effect will be rather small, and its demonstration will depend upon a very accurate isotope determination. Preliminary experiments with deuterio-D-glutamic acid emphasize the importance of these points. Presumably the use of radioactive D-glutamic acid would be more suitable; we hope to carry out a crucial experiment as soon as possible.

Further details of the investigations will be published elsewhere. Grateful acknowledgment is made to the Rockefeller Foundation for the support of our work.

Bacteriostatic Action of Oximes

THE action of numerous inorganic and organic substances on the growth of bacteria has been investigated in the hope of demonstrating properties useful either in the laboratory for selective and enrichment methods for isolation, or clinically for the treatment of the diseases which they cause. Record has not been found in bacteriological literature of the use of oximes in such an investigation.

The oximes and their derivatives used in the experiments described were kindly supplied by Dr. O. L. Brady, of University College, London. They included acetoxime, benzantialdoxime, N-methyl benzaldoxime, O-methyl benzaldoxime, salicylaldoxime and hydroxylamine hydrochloride. Each of these was tested against *Staphylococcus aureus*, β-hæmolytic streptococcus (Lancefield Group *A*), *Salmonella typhi*, *Bacterium coli*, *Proteus vulgaris* and *B. subtilis*.

Methods. For each test a series of nutrient agar plates was prepared, each plate containing a different concentration of the chemical to be tested. The concentrations were 1 : 400, 1 : 600, falling by 200 to 1 : 20,000. Suspensions in peptone water were made from well-grown 24-hr. agar cultures of the organisms. Small loopfuls of each suspension were inoculated on to the series of plates as well as on to control plates containing no oxime or derivative. After aerobic incubation at 37° C., readings of the amount of growth were taken at the end of 24 and 48 hours. In cases where all the organisms grew freely at the highest concentration of the compound, the experiments were repeated with still higher concentrations, namely, 1 : 100, 1 : 200 and 1 : 300.

Results. Acetoxime at the concentration of 1 : 400 failed to inhibit the growth of any of the organisms. It was afterwards found that the staphylococci were inhibited at 1 : 300, the β-hæmolytic streptococci at 1 : 200, and *B. subtilis* at 1 : 100. *Salm. typhi*, *Bact. coli* and *Proteus* all grew freely at 1 : 100. For the sake of brevity, the results with the other compounds are tabulated. The figures indicate the lowest concentration inhibiting the various test organisms.

Discussion. It will be observed that there is no outstanding difference in resistance or susceptibility among the different organisms tested. The hope of discovering a compound which would inhibit *B. subtilis* or prevent the swarming of *Proteus*, and yet not interfere with the free growth of organisms the

	Staph. aureus	*β Hæm. strept*	*Salm. typhi*	*Bact. coli*	*Proteus*	*B. subtilis*
Benzantialdoxime	1,200	1,200	1,200	800	600	800
N-methylbenzaldoxime	800	2,000	1,600	1,200	800	800
O-methylbenzaldoxime	800	2,000	1,200	600	800	1,200
Salicylaldoxime	2,000	4,000	2,000	1,200	1,200	1,200
Hydroxylamine hydrochloride	12,000	8,000	8,000	8,000	8,000	12,000

isolation of which was desired, was not fulfilled, as the *B. subtilis* and the *Proteus* were among the more resistant organisms. Similarly, such organisms as the β-hæmolytic streptococci and the *Salm. typhi*, the abundant growth of which is desired for their isolation and subsequent study, were among the most susceptible. The lack of marked resistance of *B. subtilis* compared with that of *Bact. coli* and *Proteus* is not unexpected, as the experiments measured the bacteriostatic and not bactericidal effect of the substances.

Aluminium Phosphate as Precipitant of Agglutinable and Non-Agglutinable Strains of *H. pertussis*

ALUMINA (hydrated aluminium oxide) is generally used to precipitate *H. pertussis* organisms from aqueous suspensions. With this adsorbent the preparation of alum-precipitated vaccines has never involved any difficulty in getting all the bacteria precipitated.

Some months ago a number of experimental vaccines were prepared with aluminium phosphate as precipitant. We noticed that a few *pertussis* strains were incompletely precipitated; this was unusual, having never occurred with alumina, and we thought it worth while to investigate the difference in behaviour of the various strains.

The strains were subjected to the customary test for agglutinability, using a phase I immune rabbit serum. It was found that the strains which had become incompletely precipitable with aluminium phosphate had also lost their ability to be agglutinated by the immune serum. To elucidate this phenomenon further, an examination was made of the twelve strains kept as stock cultures in our laboratories, and of a further thirty-three strains, freshly isolated from whooping-cough cases and kindly supplied to us by Dr. R. Cruickshank, of the Central Public Health Laboratory, Colindale. All strains were tested for agglutinability, using a formol-killed suspension prepared from each at a concentration of 2,000 million organisms per ml. Precipitability with aluminium phosphate was tested by adding 0·3 ml. of 5 per cent solution of disodium phosphate and 1 ml. of a solution of 2 per cent potash alum to 4 ml. of bacterial suspension at a concentration of 20,000 million organisms per ml. This is approximately twice the minimum amount of aluminium phosphate needed completely to precipitate the average precipitable strain. An estimate of the proportion of organisms precipitated was made by opacity measurements of the supernatant fluid about thirty minutes after the floccules had begun to deposit.

The results are summarized in the accompanying table, which demonstrates that freshly isolated strains of *H. pertussis*, as well as old laboratory cultures having a satisfactory agglutination titre, were all completely precipitated with aluminium phosphate. Stained preparations of the suspensions of the two types of strains were examined under the microscope, and it appears that the non-agglutinable were shorter and smaller than the agglutinable strains. Stained with Giemsa, the former were rather basophil; but no morphological difference could be demonstrated.

Number of strains and origin

	5 laboratory stock cultures	7 laboratory stock cultures	33 Colindale
Agglutination titre	Less than 1 : 1,000	1 : 12,000 1 : 16,000	1 : 8,000 1 : 30,000
Behaviour with phosphate	Not precipitated	Completely precipitated	Completely precipitated

Various species of bacteria other than *H. pertussis* were tested for their precipitability with aluminium phosphate. It was found that the Gram-positive cocci (*Staph. aureus, Strept. hæmolyticus* and *pneumococcus*) are completely precipitated, as also is *C. diphtheriæ* (7 strains): *Ps. pyocyanea* and *Klebsiella pneumoniæ* were not precipitated, nor was *B. coli* or *B. paracolon*. Some strains of the *B. typhosum-paratyphosum* group were precipitated and some were not. The agglutinability of the strains could not be correlated with their precipitability. Three strains of *H. parapertussis* were found to be invariably precipitated: they could not be rendered non-agglutinable by *parapertussis* immune serum, despite repeated sub-culture (over two years).

H. pertussis suspensions stored after addition of phenol or ethyl alcohol slowly lose their agglutinability. It was found, however, that organisms rendered non-agglutinable by this means were still completely precipitated by aluminium phosphate. Moreover, we observed that agglutinable organisms after aluminium phosphate precipitation retain completely their ability to adsorb agglutinins from an immune serum.

Other adsorbents were studied, and we have found that cadmium phosphate behaves in the same manner as aluminium phosphate, whereas crystalline magnesium ammonium phosphate, although a relatively poor adsorbent, does adsorb agglutinable suspensions more readily. Acriflavine (1/2,000) precipitates all suspensions irrespective of agglutinability.

A *p*H optimum at which the organisms were most readily precipitated, analogous to an isoelectric point was not found; agglutinable organisms were precipitated with equal facility over the *p*H range 4·0–10·0. At *p*H values below 4·0 precipitation does not take place, owing to solution of the adsorbent. Non-agglutinable organisms are not precipitated at any *p*H between 4·0 and 10·0.

Further indications that the two types of organism differ in surface properties were given by the finding that the agglutinable organisms are completely soluble in 0·2 *N* sodium hydroxide, or in 2 per cent solution of sodium desoxycholate, whereas non-agglutinable organisms are unaffected. There would appear to be an analogy with the bile-soluble organisms of the *Streptococcus* group (pneumococcus), which have an antigenically active surface polysaccharide.

Agglutinability and precipitability of the two types of *pertussis* organisms were not influenced by treatment with salivary amylase or urinary diastase, and Molisch's test was positive for both types of suspension. Work on the relation between the biological properties of *H. pertussis* strains (agglutinability by immune serum, virulence to laboratory animals, endotoxin production, growth requirements on semi-synthetic media) and physical behaviour towards precipitants and solubilizing agents shows a close parallelism: it is hoped to publish our findings in fuller detail elsewhere.

N. Acridyl-(5)-Alanines as Antibacterial Substances

THE occurrence of D amino-acids in several antibiotic polypeptides has stimulated interest in the correlation between the optical form of amino-acids and their effect on the antibacterial activity of certain molecules[1,2]. In furtherance of the investigation previously reported by Linnell and Smith[3], the synthesis and resolution of the ethyl ester of DL-N. acridyl-(5)-alanine has been accomplished.

Condensation of DL-alanine with 5-chloroacridine in phenol solution gave a 96 per cent yield of DL-N. acridyl-(5)-alanine as a yellow powder, m.p. 214° (found: C, 70·7; H, 5·48; N, 10·7; theory: C, 72·1; H, 5·26; N, 10·52 per cent). The monohydrate of this acid had been prepared, in 80 per cent yield, by the condensation of alanine and 5-methoxyacridine[4]. The acetate, hydrochloride and sodium salt of the above compound were prepared under anhydrous conditions; but bacteriological testing at this stage was not possible because the free acid was practically insoluble in water and aqueous solutions of the salts rapidly hydrolysed to the parent acid. A similar result has been reported for N. acridyl-(5)-glycine by Dupré and Robinson[5].

Esterification with ethyl alcohol in the presence of dry hydrochloric acid gas gave an 80 per cent yield of the racemic ester. This crystallized from aqueous alcohol as small yellow prisms, m.p. 75° (found: N, 9·25; H, 6·26; theory: N, 9·52; H, 6·12 per cent). The ester gave well-defined crystalline compounds with picric and picrolonic acids, and its diacetate and monohydrochloride were quite stable in aqueous media. A preliminary test showed that a 0·1 per cent aqueous solution of the diacetate possessed antibacterial activity against *Staphylococcus aureus* and *Streptococcus pyogenes*.

Resolution of the racemic ester was achieved by the use of (+) tartaric acid. An 87 per cent yield of the racemic ester (+) bitartrate was obtained by mixing hot absolute alcohol solutions containing equivalent quantities of the ester and (+) tartaric acid. This salt was a deep yellow powder, m.p. 165°, $[\alpha]_D^{20} = +18°$ (water, $C = 4·0$). Fractional crystallization from 80 per cent alcohol gave the (+) ester (+) tartrate as long yellow needles, m.p. 118°, $[\alpha]_D^{20} = +54·5°$ (water, $C = 4·0$). Evaporation of the mother liquors and repeated crystallization of the residue from absolute alcohol gave the (−) ester (+) tartrate as a yellow powder, $[\alpha]_D^{20} = -19·5°$ (water, $C = 4·0$).

The ester isomers were isolated by extracting aqueous solutions of their respective (+) tartrates, which had been made alkaline with ammonia, with benzene. They were obtained as viscous yellow oils, (+) N. acridyl-(5)-alanine ethyl ester, $[\alpha]_D^{20} = +128°$ (96 per cent alcohol, $C = 2$); (−) N. acridyl-(5)-alanine ethyl ester, $[\alpha]_D^{20} = -122°$ (96 per cent alcohol, $C = 2$).

Preliminary bacteriological tests on aqueous solutions of the (+) tartrate showed that these salts caused inhibition of growth in the following dilutions:

Organism	Racemic ester (+) bitartrate	(+) ester (+) tartrate	(−) ester (+) tartrate
(1) *Staphylococcus aureus*	1/6000	1/6000	1/3000
(2) *Streptococcus pyogenes*	1/4000	1/4000	<1/2000

A fuller account of this work is to be published elsewhere. The preparation and resolution of DL-β acridyl-(5)-alanine is now being investigated, and it is proposed to include other amino-acids in later work.

Genetic Transmission of Two Rare Blood-Group Genes

To date no data of families have been published which illustrate the genetic transmission of the rare gene r^y, and only but one or two families which illustrate the transmission of gene R^z.

Recently, four families were encountered which illustrate the genetic transmission of the genes r^y and R^z in striking fashion. Because of the rarity of such cases, it seems important to record them, and they are listed in the accompanying table.

Families illustrating genetic transmission of the rare genes R^z and r^y

Case number		Parents		Children		
		Father	Mother			
1	Phenotype	Rh_1Rh_2	rh	rh	Rh_1Rh_2	Rh_1Rh_2
	Genotype	R^zr	rr	rr	R^zr	R^zr
2	Phenotype	rh′rh″	rh	rh	rh′rh″	
	Genotype	r^yr	rr	rr	r^yr	
3	Phenotype	Rh_1Rh_2	rh	Rh_1Rh_2		
	Genotype	R^zr	rr	R^zr		
4	Phenotype	Rh_1Rh_z	rh	Rh_1rh	Rh_1Rh_2	
	Genotype	$R\,R^1$	rr	R^1r	R^zr	

Incidentally, these more complicated cases serve to underline the importance of avoiding ambiguity between the designations for the phenotypes and genotypes.

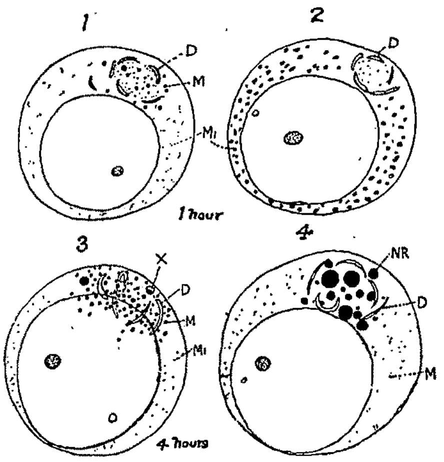
Methylene Blue as a Vital Stain for the Golgi Apparatus

Experiments have been made with five specimens of methylene blue as a vital stain for the spermatocytes of *Helix aspersa.* The specimens were an old German 'polychrome methylene blue', and four others, 'pure methylene blue', and just 'methylene blue'.



In a suitable concentration all the specimens acted in the same way, being segregated into small droplets (M) inside and outside the Golgi apparatus (D), neither the mitochondria, M_1, nor the lenticular dicytosomes staining (Fig. 1). At a higher concentration of the dye (not the polychrome methylene blue) the mitochondria stained intensely, rivalling the best Janus green vitally stained cells (Fig. 2). In many of these cases the methylene blue granules associated with the Golgi apparatus (Fig. 1) did not appear. The polychrome methylene blue at these higher, perhaps lethal, concentrations tended to stain the mitochondria blue and rarely the dictyosomes of the Golgi apparatus a reddish colour. The main difference between methylene blue and neutral red as vital dyes for *Helix* spermatocytes is that the methylene blue can be made to stain mitochondria or to segregate into droplets in the region of the Golgi apparatus, whereas neutral red does not stain the mitochondria or Golgi dictyosomes, but easily segregates into droplets which grow in size according to the length of time the cells are exposed to the dye. In Fig. 3 is a cell which has been exposed to a weak methylene blue solution for four hours. The number of methylene blue segregation artefacts has increased very greatly, the dictyosomes are still unstained and in rare cases the methylene blue segregation cavities may be large (X). Generally speaking, these cavities do not become as large as the neutral red artefacts (Fig. 4, after four hours).

It is interesting to note that the methylene blue segregation artefacts shown in Fig. 3 are spread both inside and well outside the region of the Golgi apparatus. In more highly differentiated cells, such as nerve or salivary cells, the behaviour of the methylene blue dye will be more complicated.

It is hoped to publish the results of these and other experiments on methylene blue and Sudan Black B elsewhere in a fuller form.

Passage of Hæmoglobin from Blood into Eggs of *Daphnia*

It is known that the amount of hæmoglobin dissolved in the blood of *Daphnia* varies inversely with the oxygen content of the water in which the animals live. The changes in concentration of the hæmoglobin have been studied by a quantitative method which allows measurements to be made on a single *Daphnia*: the colour of the animal's blood is compared under the microscope with known dilutions of human blood[1]. In the course of further work involving the use of this method it was noticed that parthenogenetic females with eggs in the brood pouch have less hæmoglobin in their blood than those with embryos in the pouch. The difference is greatest in populations producing numerous young.

The parthenogenetic eggs of *Daphnia* contain hæmoglobin[2]. It can be seen under the microscope with reflected light that the ovaries become progressively pinker as they enlarge during the last few hours preceding egg-laying. The microspectroscope shows that this pink colour is that of oxyhæmoglobin. Moreover, at the same time as the pink colour is increasing in the ovaries, the blood becomes paler. This decrease in the hæmoglobin content of the blood may amount to one-third. The inference is that hæmoglobin passes from the blood into the eggs as they develop in the ovary. The course of the decrease during the six hours before the moult, which immediately precedes egg-laying, has been studied quantitatively in a number of individual *Daphnia.* It is at first gradual and then rapid. Part of the final decrease in the pink colour of the blood is due not to a loss of hæmoglobin but to a dilution of the blood resulting from the moult and the increase in body-size which is its consequence. This dilution, however, accounts only for a small proportion of the decrease in blood colour. After egg-laying, the hæmoglobin of the blood is gradually regenerated to its original level. The course of this regeneration has been followed quantitatively over the 2–3 days during which the embryos develop in the brood pouch and are finally liberated prior to the next moult.

The molecules of *Daphnia* hæmoglobin appear to be of two sizes, with weights respectively one-half and six times that of mammalian hæmoglobin; the larger molecules are the more abundant[3]. The passage of this protein from the blood into the ovary raises an interesting problem. Either the blood hæmoglobin must be rapidly broken down and the products rapidly resynthesized in the ovary, or else the hæmoglobin molecule as such crosses the cell membranes. This would not be the sole case where the passage of a protein molecule across a cell membrane is suspected. Other examples are found in the secretion of hormones and enzymes, virus penetration and the particularly relevant case of the acquisition of passive immunity in birds' eggs. Here the antitoxin passes from the blood serum of the bird into the eggs[4,5].

A full account of this work will be published elsewhere. I wish to express my sincere thanks to Prof. H. Munro Fox for his interest and advice.

Effect of Carbon Dioxide on Availability of Manganese in Soil Producing Manganese Deficiency

A SERIES of experiments, extending over several years, in which potato plants were grown both in pots and in the field, in soil producing manganese deficiency, from the recently drained lake-bed at East Malling Research Station, has led us to suspect the presence of some hitherto unexplained factor influencing manganese availability. The soil in question is an alluvial deposit containing a large amount of calcium carbonate and organic matter and has a *p*H of 8·0–8·5. The soil contains ample manganese, as simple extractions in Morgan's solution yield considerably more than 50 p.p.m. of manganese on a dry soil basis. This, however, is only a small fraction of the total, as is shown by extractions with strong acid. The amount of manganese available to the plant is, on the other hand, very small, since plants containing less than 1 p.p.m. on a fresh weight basis and showing acute deficiency symptoms are of common occurrence in certain areas of the lake-bed. Attempts to reproduce these conditions using the same soil in pot culture never succeeded in producing plants showing such marked symptoms or low manganese contents, although the soil *p*H was maintained between 8·0 and 8·5 by irrigating with water saturated with calcium carbonate. Water extracts of soil taken either from pots or the lake-bed itself showed negligible amounts of extractable manganese, although the plants grown in pot culture in the summer of 1948 showed no manganese deficiency, while those grown in 1947 were much less deficient than those growing on the lake-bed.

Consideration of these facts led to the hypothesis that local accumulations of carbon dioxide within the root-masses might render manganese available without producing perceptible changes on the *p*H of the soil as a whole. The following experiment was therefore carried out. Some uniformly mixed soil (water content 9·0 per cent) was collected and finely ground. Portions of 250 mgm. each were weighed out into 150 ml. conical hard-glass flasks, well corked, and were left in contact for forty-eight hours with high-grade water re-distilled in quartz. The water used was divided into two parts, one of which was saturated with acid-free carbon dioxide at 20° C. and the other boiled. Mixtures in varying proportions were used, keeping the total volume at 25 ml. A flask was also set up in which the water was kept saturated with carbon dioxide during the extraction. After extraction the liquid was centrifuged to remove soil particles, and the *p*H and amount of manganese extracted determined. The results are given in the accompanying table.

ml. boiled water	ml. water saturated with CO_2	p.p.m. of Mn extracted calc. on dry soil	*p*H of extract
25	—	<0·1	8·0–8·5
24	1	<0·1	8·0–8·5
23	2	<0·1	8·0–8·5
21	4	<0·1	8·0–8·5
17	8	0·4	8·0
9	16	2·6	7·5
—	25	5·6	7·5
—	25 kept sat. with CO_2	22·0	6·0

Owing to the extremely localized accumulation of carbon dioxide likely to occur in the soil, and the large excess of calcium carbonate present, no general changes in *p*H have been detected in the pot cultures, which remained uniformly above *p*H 8·0.

The liberation of manganese by these local accumulations of carbon dioxide would go far to account for the patchy distribution of symptoms found in the field and the higher manganese contents of pot plants with a more compacted root system. Owing to the rain early in the summer of 1948 the soil of the pots was saturated with water for several weeks, while in 1947 these conditions did not occur, which may explain the observed differences in manganese uptake.

Protection of Grain against Weevils

TO-DAY, the losses of foodstuffs caused by insects, principally weevils, often disregarded in pre-war days, cannot be overlooked. A conservative estimate has been made that on the average losses of ten per cent of all stored food are caused by insects[1]. In the tropics the life-cycle of weevils and other insect pests is accelerated as the temperatures are close to the optimum and, furthermore, breeding is continuous throughout the year, so that the losses can attain appalling proportions—samples of grain offered for sale have been seen in which more than 50 per cent of the individual grains have been seriously damaged. In such infested grain there is a further attack by the flour beetle, *Tribolium castaneum*, which spoils the little good grain remaining by the taint.

During the last few years investigations have been in progress on inert dusts of local origin, some of which, notably diatomite, have been found to give fair protection. Jepson[2], in Tanganyika, has most successfully employed a 'Gammexane' dust diluted with diatomite, at a rate to provide 1 p.p.m. of the gamma isomer. The Ministry of Food has objected to this very small concentration on the grounds of possible poisonous effects; true, there is a danger of applications of the dust being made by each successive handler. Pyrethrum powder, a local product, has often been suggested as a protectant; but on account of its supposed short life has not been used. In September last an experiment was started in which diatomite, diatomite–pyrethrum dusts and pure pyrethrum powder were used. Four types of grain were included: clean maize, weevily maize, clean wheat and weevily wheat; unfortunately the 'clean' maize became infested *en route* and should be placed in the category of 'slightly weevily'. Six treatments were included, namely: untreated; diatomite alone, at the rate of 2 lb. per 200-lb. bag; three diatomite–pyrethrum dusts of increasing pyrethrum concentration, also at the rate of 2 lb. per 200-lb. bag; and, finally, pyrethrum powder, fairly finely ground, at the rate of 1 lb. per bag. Each treatment was replicated four times, and the bags were stacked in a randomized block, which ensured continuous infestation of the whole stack from the untreated weevily bags.

At the end of a week, counts made on random samples drawn from all the bags in the stack revealed that all the treatments had reduced the numbers of living weevils to a highly significant degree. Complete protection was given by all pyrethrum treatments over three months, though in the diatomite lot a few live weevils were found. At the end of six months, the infestation in the bags treated with the weakest pyrethrum–diatomite dust (20/80) had become mild. Complete protection has been afforded by the other two dusts and the pyrethrum powder for eight and a half months when, for the first time, random samples revealed living weevils in significant numbers. At the end of this period the untreated 'clean' wheat contained 57·3 per cent of damaged grains; the grain treated with diatomite alone 12·5 per cent; that with the weakest dust 3·5 per cent; while only a fraction of 1 per cent was damaged in those protected with the two stronger dusts and pyrethrum powder. There is evidence that an application of less than 1 lb. a bag will provide adequate protection, especially if the powder be more finely ground[3].

Perhaps the most interesting point established in these experiments is the unexpectedly long life of pyrethrum powder in bagged grain. Since the effect is very rapid, there would be no chance of stray weevils entering bags of grain treated with pyrethrum powder being able to lay eggs. The long protection given would also tend to destroy weevils emerging from grain lying on the floor of the warehouse; thus, complete protection for a much longer period than eight months may be confidently expected.

The detailed results of these experiments will be published elsewhere.

Fast Neutron–Proton Scattering and the Law of Interaction between Nucleons

IN order to use the results of experiments on the scattering of high-energy neutrons by protons to obtain information about nuclear interactions, it is necessary to calculate the expected angular distribution of the scattered neutrons and the total collision cross-section for a large variety of different possible types of nuclear interaction.

Until now, practically all calculations of the scattering which have taken account of non-central forces have assumed a spherical well, radius $2 \cdot 80 \times 10^{-13}$ cm., as the shape of the interaction. Recently Hu and Massey, in a paper to appear shortly in the *Proceedings of the Royal Society*, have calculated the appropriate interaction constants for a number of different shapes of interaction. Following Rarita and Schwinger[1], they investigated three types of the n—p interaction with exchange properties suggested by the symmetrical, charged and neutral meson theories, which we shall call interactions I, II and III respectively. For states of even parity the interactions were taken as the same for each type of force, namely,

$${}^1V_{\text{even}} = -\frac{\hbar^2}{Mr_0^2}\, gV\left(\frac{r}{r_0}\right),$$

$${}^3V_{\text{even}} = -\frac{\hbar^2}{Mr_0^2}\, a\,(1+\gamma S_{12})\, V\left(\frac{r}{r_0}\right),$$

r being the range of the interaction, S_{12} the tensor force operator, and g, a, γ dimensionless constants; this g is not the same as the g used by Rarita and Schwinger.

The interaction functions $V\left(\frac{r}{r_0}\right)$ investigated were of the following forms:

(1) Spherical well $V\left(\frac{r}{r_0}\right) = 1$ for $r < r_0$
$\phantom{V\left(\frac{r}{r_0}\right)} = 0$ for $r > r_0$

(2) Yukawa potential $V\left(\frac{r}{r_0}\right) = \left(\frac{r_0}{r}\right)\exp\left(-\frac{r}{r_0}\right)$

(3) Exponential potential $V\left(\frac{r}{r_0}\right) = \exp\left(-\frac{r}{r_0}\right)$

(4) Gaussian potential $V\left(\frac{r}{r_0}\right) = \exp\left\{-\left(\frac{r}{r_0}\right)^2\right\}$

For a variety of ranges, r_0, Hu and Massey determined a, g and γ to give correctly the binding energy, the energy of the virtual singlet state, and the quadrupole moment of the deuteron.

A knowledge of these interaction constants has made possible a systematic investigation of the dependence of the total cross-section and angular distribution in high-energy n—p scattering on the range and shape of the assumed interaction. Accurate calculations of this type are at present being carried out in this Department for incident neutron energies in the range 100–250 MeV. These calculations are very lengthy, however, and in the meantime we have used the Born approximation to calculate the scattering in this energy range.

Ashkin and Wu[2] have investigated the validity of this approximation in the case of the spherical well of range $2 \cdot 80 \times 10^{-13}$ cm. They found that, although it is not very good at neutron energies of 100 MeV., it gives fairly good agreement with exact calculations for neutron energies of 200 MeV., the agreement being poorest in the case of interactions of type II.

In general, the Born approximation appears to give rather too large a value of the total cross-section. This is shown, for example, in Table 1, which compares the total cross-section as calculated by the Born approximation in the present work with exact values obtained previously by Massey, Burhop and Hu[3]. These values refer to a spherical well interaction of range $2{\cdot}80 \times 10^{-13}$ cm., and incident neutrons of energy 83 MeV.

Table 1

	Total cross-section ($\times 10^{26}$ cm.^{2})			Ratio $\sigma_{180°}/\sigma_{90°}$		
	Inter. I	Inter. II	Inter. III	Inter. I	Inter. II	Inter. III
Exact theory	14·10	15·77	23·38	10·2	3·67	0·58
Born approximation	19·05	23·32	28·32	11·3	3·56	0·53

Table 1 shows also that the ratio $\sigma_{180°}/\sigma_{90°}$ of the differential cross-section at 180° to that at 90° in the c.m. system is given fairly well by the Born approximation.

For other forms of interaction one would expect the Born approximation to give better results than in the case of the spherical well. Thus, for a purely central type of Yukawa interaction of range $1{\cdot}18 \times 10^{-13}$ cm. and symmetrical forces, Chew and Goldberger[4] found that the Born approximation gives a total cross-section about 7 per cent too large at 100 MeV.

(4) The decrease of total cross-section with increase of neutron energy is more rapid with the longer range interactions.

(5) The spherical well shape of interaction tends to give a larger total cross-section and a smaller ratio of $\sigma_{180°}/\sigma_{90°}$ than the other shapes. This, however, could arise partly from the poorer accuracy of the Born approximation in the case of the spherical well.

The Berkeley measurements of the total cross-section gave the value $8{\cdot}3 \pm 0{\cdot}4 \times 10^{-26}$ cm.^{2} for 90 ± 13 MeV. neutrons[5]. Of all the interactions investigated, the only one that gives a value approaching this is the Yukawa potential of range $1{\cdot}18 \times 10^{-13}$ cm. for type I interaction, which gives a value of $9{\cdot}1 \times 10^{-26}$ cm.^{2}. According to the interaction constants given by Chew and Goldberger[4] and used for this range, the triplet interaction in this case is almost wholly non-central.

The provisional experimental value[6] of $\sigma_{180°}/\sigma_{90°}$ is about 3. This seems to rule out any kind of type III interaction. The Yukawa symmetrical case of range $1{\cdot}18 \times 10^{-13}$ cm. gives about 6·2 for this ratio. It seems to be a feature of the angular distribution in the case of the Yukawa potential with type I interaction, however, that there is a sharp increase in differential cross-section at scattering angles near 180°. In such a case an experimental measurement might be expected to give a value of $\sigma_{180°}/\sigma_{90°}$ somewhat too small.

A full account of these calculations will be published elsewhere.

Table 2

Shape of Interaction	Range $\times 10^{13}$ cm.	Total cross-section ($\times 10^{26}$ cm.^{2}) Inter. I		Inter. II and III		Ratio $\sigma_{180°}/\sigma_{90°}$ Inter. I		Inter. II		Inter. III	
Neutron energy in laboratory system (MeV.)		100	250	100	250	100	250	100	250	100	250
Spherical well	3·49	19·0	7·5	22·1	8·5	75	1240	37	757	0·12	0·68
	3·05	17·6	7·4	20·3	8·1	25·8	2190	8·9	942	0·26	0·40
	2·80	17·0	7·7	20·7	8·7	12·9	136	3·7	48·2	0·30	0·05
	2·62	16·8	8·0	22·2	10·0	7·6	36·5	1·5	8·7	0·44	0·04
	2·18	25·5	15·3	48·9	30·8	2·4	3·1	0·44	0·62	0·98	0·01
Yukawa potential	2·18	14·1	6·0	16·6	6·6	90	397	64·8	269	0·34	0·31
	1·74	11·9	5·5	13·8	6·4	38	152	18·9	64·4	0·40	0·35
	1·18*	9·1	5·9	16·5	10·4	6·2	14·3	0·61	1·29	0·59	0·43
Exponential potential	1·09	15·3	6·2	17·6	7·0	99·5	562	43·0	237	0·28	0·20
	0·87	12·6	5·9	15·3	7·1	22·7	102	8·5	31·9	0·39	0·25
Gaussian potential	2·18	14·9	6·5	17·7	7·5	32·9	266	12·3	91·9	0·25	0·13

* The constants used for this range are approximate ones given by Chew and Goldberger[4].

Table 2 shows the results of the present calculations. Some general conclusions to be drawn from this able are as follow:

(1) The total cross-section for interaction types I and III is always larger than for type I.

(2) The ratio $\sigma_{180°}/\sigma_{90°}$ is greatest for interaction I nd always less than 1 for interaction III.

(3) As the range of interaction decreases, the total ross-section passes through a minimum and then tarts to increase again while the ratio $\sigma_{180°}/\sigma_{90°}$ coninually diminishes. The increase of the total cross-ection at very short ranges is associated with the ncreasing importance of the tensor force. In the xtreme case of a spherical well of range 2·18 × 0^{-13} cm., the non-central interaction is so large that he central interaction has to be made repulsive to ive the correct deuteron binding energy.

We are greatly indebted to Prof. H. S. W. Massey and Dr. Tsi-Ming Hu for allowing us to use, prior to publication, the interaction constants calculated by them, and for valuable discussions during the course of the present work.

Photo-Elastic Effect in Barium Nitrate

During the course of our investigations on photo-elasticity, we have found that single crystals of barium nitrate behave in many respects in an exceptional manner. Differences between the stress-optical constants as determined by a Babinet compensator are $(q_{11} - q_{12}) = -23 \cdot 81 \times 10^{-13}$, $(q_{11} - q_{13}) = -18 \cdot 06 \times 10^{-13}$ and $q_{44} = -1 \cdot 62 \times 10^{-13}$ C.G.S. units for the sodium *D* lines. $(q_{11} - q_{12})$ and $(q_{11} - q_{13})$ furnish a measure of the birefringence caused when pressure is applied along a cube axis.

Values given above for barium nitrate are the largest so far obtained for any cubic crystal. These values are not only larger than those hitherto reported for other cubic crystals, but are also larger than the corresponding value for most glasses, which does not generally exceed 10×10^{-13}. Barium nitrate crystals belong to the T_h class and we would expect $(q_{11} - q_{12})$ to be different from $(q_{11} - q_{13})$. It is an interesting feature that the difference in this case is nearly 27 per cent, and is much larger than that observed by us earlier in potassium and ammonium alums[1]. It is also to be noted that for this substance the birefringence produced by a pressure along a cube axis is nearly fifteen times that produced by an equal pressure along a cube diagonal. This should be regarded as a large anisotropy, as the corresponding figure for potassium alum, its nearest approach, is only eight times.

Inclusions in Aluminium Crystals

It appears from various experiments that the ease with which a crystal can grow in a deformed matrix depends very much on the mutual orientation of growing and disappearing lattice domain. This is already obvious from the fact that, in a recrystallizing coarse-grained material, the new crystals show corrugated boundaries, demonstrating visibly that some of the original grains are consumed at a faster rate than others[1]. Recent experiments give a far more striking proof of this phenomenon.

It was observed by Carpenter and Elam[2] in their original paper on the preparation of aluminium crystals by the stress-strain method that the large crystals so obtained often contain small included domains with deviating orientation, which were obviously unabsorbed grains from the original fine-grained material. These inclusions proved to be very stable against prolonged heat treatment (see, for example, Seumel[3]).

It struck us that in a crystal with a number of inclusions, several of these domains reflected incident light at the same moment, thus pointing to a more or less identical orientation. It seemed worth while to determine this orientation, and to look for a relation between the orientation of the 'mother crystal' and the orientation of the included domains. As the dimensions of these domains depend on the grain size of the matrix, they can vary considerably, so that it is not always possible to determine the orientation of an inclusion by X-ray methods. In these cases the etch method, developed for aluminium by Lacombe and Beaujard[4], was used. By this method tiny cubic etch-pits are developed, and the boundary lines of the pits are therefore traces of (100) planes on the surface of the test piece. Starting from the orientation of the mother crystal (determined from a Laue transmission photograph), the (100) traces to be expected for the four spinel twin orientations were constructed by means of stereographic projection. It was found that the pits in the inclusions had orientations which coincided with the four twin possibilities within about 5°. Fig. 1 shows two different twins in the same mother crystal.

The orientation of larger inclusions (approximately 0·2 mm. diameter) could be obtained by X-ray methods (Laue transmission photographs). These photographs consisted of the superimposed Laue patterns of mother crystal and inclusion; as the pattern of the included domain showed a marked asterism as a result of the deformation before recrystallization (this proves at the same time that the included domain is no new crystal), it was not difficult to separate them. The photographs confirmed the relationship between the orientations already found by the etch method. Fig. 2 shows the Laue patterns of mother crystal and inclusion superimposed; the enclosed spots would have coincided for an exact twin relationship.

According to these experiments, it seems to be difficult for a growing crystal to consume those lattice blocks which occupy approximately a twin position. From this it might be deduced that in order to prepare large aluminium crystals by the stress-strain method without such inclusions, one has to start from fine-grained material of such 'narrow' texture that a growing crystal has no chance of meeting its (approximate) twin position. A second point is the striking difference in behaviour between grains in *approximate* twin position and lattice blocks which give rise to exact twins. As was found in earlier work[5], a growing crystal may induce ('stimulate') a block to become an active nucleus, which develops into an exact twin with regard to the stimulating crystal (for a more extensive account on exact twins in aluminium and the idea of 'stimulation' we refer to ref. 6).

At the moment, we have not yet been able to analyse the geometrical relationship between two

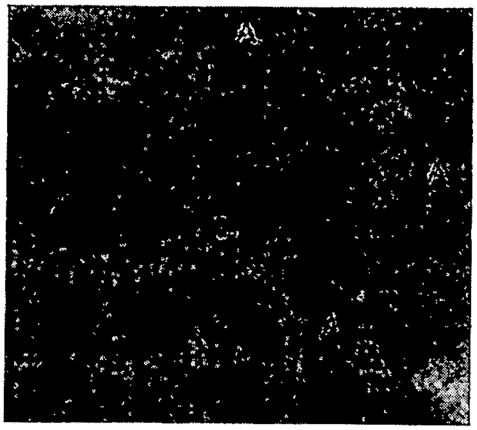

Fig. 1. Part of an aluminium crystal, *A*, containing an 'unconsumed' inclusion, *B*, with cubic etch pits. From the relative position of the etch pits it can be deduced that the inclusion *B* is approximately a spinel twin with regard to *A*. × 300

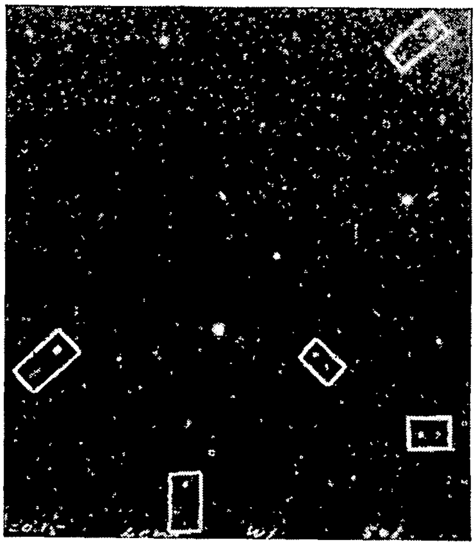

Fig. 2. Superimposed Laue patterns of a large aluminium crystal (sharp spots) and of an unconsumed inclusion of the original deformed matrix (slightly elongated spots). Pairs of spots enclosed by ▭ would coincide if the orientation relationship between crystal and inclusion was exactly that of a spinel twin

win orientations sufficiently to understand why con-umption of an approximate twin lattice is apparently o difficult.

Note added in proof. In recent work by P. A. eck, M. L. Holzworth and Ph. Sperry on grain rowth in Al–Mn alloys (1948) it was similarly found hat the large crystals, which develop on continued eating of special fine-grained recrystallized material y a process of 'exaggerated' or 'discontinuous' grain-rowth (also called 'secondary recrystallization'), eave unconsumed definite small grains of the original matrix: Prof. Beck kindly put some of his crystals t our disposal, and here also the same 'approximate win-relation' between large crystal and imbedded nclusion was found.

Electrokinetic Potentials of Aged Barium Sulphate Crystals

ELECTROKINETIC methods can be used with great dvantage in the study of the adsorption of electro-tes or potential-determining ions on crystalline bstances. One of us[1] determined the streaming otentials in diaphragms of precipitated and aged arium sulphate, as a function of the composition of e bathing electrolyte solution. Reyerson, Kolthoff d Kieth Coad[2] have recently confirmed in a general ay these results, with the exception that they found constant negative charge in hydro-alcoholic (50 per cent) solution of potassium chloride (10^{-5} *M*). Ruyssen[1] had found that by the replacement of the aqueous potassium chloride solution by a hydro-alcoholic one the initial negative charge was reversed.

We have re-investigated the point under discussion with the same samples of barium sulphate and the following experimental facts were definitely established: (1) The charge of the barium sulphate was negative in both aqueous and hydro-alcoholic potassium chloride (10^{-5} *M*) solution, provided these were the first solutions with which the crystals came in contact. (2) When the aqueous potassium chloride solution was displaced by a hydro-alcoholic one, the measured charge became positive. When the crystalline substance was taken out of the diaphragm and thoroughly washed and shaken with the same liquid, its charge was again reversed to negative. (3) When the hydro-alcoholic solution of the first experiment was displaced by pure water, the crystals were charged positively. (4) In a saturated barium sulphate solution, without other electrolytes, the crystals became again negatively charged.

We may conclude that the normal equilibrium charge of pure barium sulphate is negative in aqueous potassium chloride solution and saturated barium sulphate solution as well as in hydro-alcoholic potassium chloride solution. This is in agreement with Reyerson *et al.*[2], but not with the positive streaming potentials found by Buchanan and Heymann[3] of natural barytes and recrystallized barium sulphate. On the other hand, we confirmed the experimental fact of the reversal of the charge of the barium sulphate when the aqueous solution is displaced by a hydro-alcoholic one, although this seems not to be the equilibrium charge. It seems that in the hydro-alcoholic medium there is a precipitation of the barium sulphate out of the displaced saturated aqueous solution, followed by preferential adsorption of the Ba^{++} ions.

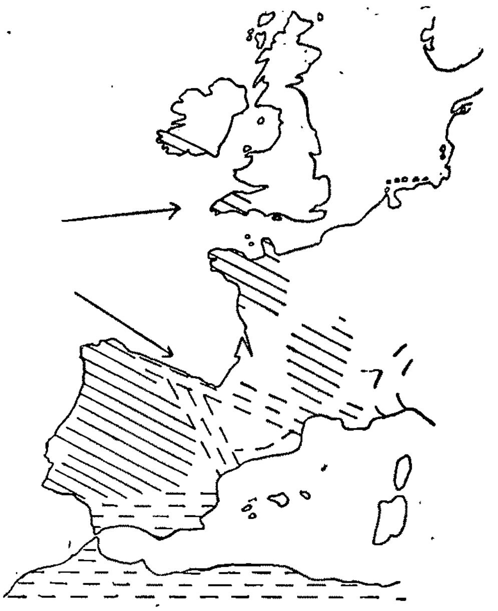
Factors Controlling the Atlantic Coastline of Europe

IN 1938, W. V. Lewis[1] pointed out that the general line of a shore tends to be at right angles to the direction of dominant wave-attack, and that as a bay becomes adjusted to this attack it tends to become asymmetrical, with the longer, smoother side facing the quarter from which the dominant waves approach. In 1940[2], I suggested that the theory applied by Mr. Lewis to beach material and easily eroded cliffs might be developed to explain the outline of the larger bays of south-west England. I showed that this would account for the fact that their eastern sides have been rendered comparatively smooth, with blunted headlands, while their western sides have been protected from dominant wave-attack, so that their indented minor bays have been preserved between angular promontories.

Various geologists have since suggested to me that this view of coastal development may be applicable to widely scattered parts of the world. In particular, I am indebted to Mr. E. E. S. Brown (now president of the Geologists' Association) for pointing out to me that both the west coast of Ireland and the Bay of Biscay are exposed to the full force of the Atlantic, while the coast of north Spain runs parallel to the line of wave-attack and is thus comparable with the coast of north Devon. These suggestions have led me to a further study of the map of western Europe from this point of view.

The outline of the Atlantic coast of France, Spain and Portugal is notable for its relative simplicity, the single northward-facing stretch turning at either end almost at a right angle into the westward-facing sectors. If wave-attack has been largely responsible for the smoothing of the westward-facing coasts, this is an illustration of the power exerted when the direction of prevailing winds happens to coincide with the direction of the greatest stretch of open ocean. In western Europe, the Westerly winds blow direct off the open Atlantic. The relation of the shore to wave-attack may possibly be very different on a coast such as that of eastern Canada, where the prevailing wind is offshore.



Sketch-map of Western Europe ; Armorican structure shown by continuous lines, Alpine structure by broken lines. Arrows indicate approximate direction of prevalent winds. (Bonne's projection)

Moreover, in western Europe the direction of the open ocean and prevailing winds happens to lie at right angles to the principal structural lines. The northern limit of Armorican, otherwise known as Hercynian, folding (originating in Permo-Carboniferous times) ran approximately east and west through south-west Ireland and southern England, resulting in the mountain ranges, now worn down to mere stumps, of Devon and Cornwall and of Brittany. Following the older Caledonian lines of weakness, running in a rather more north-east to south-west direction, granites were injected into Devon and Cornwall ; the granite of the Land's End protects the peninsula rather as the ferrule protects a walking-stick. A corresponding series of igneous and metamorphic rocks form the backbone of the Breton peninsula. The English Channel has eaten its way into the lower ground between Cornwall and Brittany, and, still farther south, the west of France is traversed by valleys where a submergence of about 600 ft. would unite the Bay of Biscay with the Gulf of Lions in a strait through the 'Gate of Carcassonne'.

The next rib in the skeleton of western Europe is the Pyrenees, which, although dating from the Alpine orogeny of Tertiary times, follow the same east and west axis as the earlier Armorican folds. Thus the general trend of the north coast of Spain runs straight from the Alpine Pyrenees into the Alpine and Armorican Cantabrians. The great block of the Iberian peninsula consists of the Meseta, which is lapped round in the south by the Betic Cordillera folded in the Alpine period. The structural control is continued in North Africa by the Alpine range o the Atlas Mountains, the sea having broken through between the Atlas and the Betic Cordillera to form the Strait of Gibraltar. Much of the Atlantic coast of Spain and Portugal lies in 'Mediterranean' latitudes south of the Westerly wind belt, but owing to the relation of land and sea it is not exposed to the North East Trades, and even in summer the winds have a westerly component. However, the Iberian coast presumably depends more for its form on structure and less on relation to winds and waves than does the coast north of the Cantabrians.

It is the east–west folds which, owing to the coincidence of the Armorican and Alpine axes, have acted as the supporting structure of western Europe holding out the land into the Atlantic Ocean, which has eaten its way back or broken right through wherever the protection of mountain or igneous rock was lacking. Thus the coast between the east–west mountain ribs has been worn back in a north–south direction under the attack of the waves. Thes waves are driven by the Westerly winds approaching over the open Atlantic approximately at right angle to the main structural lines of western Europe.

'Pins and Needles'

It is well known that the release of a constricting cuff, which is cutting off the blood-supply to a pa of a limb, may be followed by the complex sensatio known as 'pins and needles' ; but there has bee some controversy as to which part of the nerve or i branches is giving rise to the nerve impulses. Lew *et al.*[1] and Zotterman[2] believed that the region of th nerve lying under the cuff was mainly concerne whereas Weddell and Sinclair[3] argue that the sensation "is due to the stimulation of a proportion of th peripheral nerve endings in the area in which it felt". Some new experiments to be described gi results which appear incompatible with either these views.

The pricking sensation of 'pins and needles' wa produced by the release of a blood-pressure cu placed just above the elbow, which had cut off th blood-supply to the forearm and hand for twel minutes. The pricking sensation in the normal ar was compared with the sensation felt after blocking the ulnar nerve or its branches at various levels with procaine.

A block at the elbow, just below the cuff, entirely eliminates the sensation, which must mean that the 12-cm. stretch of nerve lying under the cuff cannot be the origin of all the impulses, or even of a majority of them, as Lewis *et al.*[1] suggested. A block of the ulnar nerve branches in the hand, however, which makes the whole or a part of the ulnar skin area anæsthetic, has only the effect of modifying the sensation, the pricks being fewer and less intense, but nevertheless clearly felt in the anæsthetic skin area. This argues against the conclusion of Weddell and Sinclair[3], since the peripheral endings are, in this case, taking no part in the production of the sensations which are perceived.

The effect of a block half-way between these extremes (that is, mid-forearm) is particularly interesting. The sensation is far less intense than with a block in the hand, although the same skin area is anæsthetized in either case: the pricks are now very few, and although clearly-felt as pricks, they are individually less intense than in normal unanæsthetized skin.

These experiments suggest that the intensity and number of the pricks depend on the length of nerve which is recovering from any fixed period of depressed blood-supply, and that no part of a nerve is particularly concerned in generating the impulses which give rise to this form of 'pins and needles'. This probably explains why the pricking of 'pins and needles' is less intense when produced by a cuff at the wrist, and very feeble indeed with a cuff around a finger.

The change in the physico-chemical circumstances governing the excitability of any one nerve fibre, which occurs as the circulation is restored (the removal of a 'substance'[3]), presumably offers to all parts of that fibre the opportunity of firing off impulses, and the chance of some low-threshold point or points becoming rhythmically active should be increased when a greater length of the fibre is exposed to the changed environment.

A fuller account and discussion of this work will be published elsewhere in due course.

Persistence of D.D.T. in the Soil

THE note by M. S. Smith[1] concerning the persistence of D.D.T. and 'Gammexane' in soil is in conformity with the results of experiments carried out in Australia on the use of D.D.T. as a control of the scarab *Aphodius howitti* Hope, the larvæ of which infest pastures on the tablelands of south-eastern Australia.

The species has a simple annual life-cycle, the adult flights occurring in February. D.D.T. was applied to the pasture as a 2 per cent dust in talc at the rate of 3·3 lb. of *pp*-isomer D.D.T. per acre in August 1946. At this time the larvæ had almost completed their active feeding stage. No significant mortality resulted from the treatment. However, in the winter of 1947, the treated areas were completely free from infestation, while adjacent untreated areas were again infested. Indirect evidence suggests that the D.D.T. had its effect on the very young larvæ of the 1947 generation, approximately eight months subsequent to the date of treatment.

On the basis of Smith's results, it may reasonably be expected that the D.D.T. will have persisted and exercised a control of the larvæ of the 1948 generation. At the time of writing, larvæ are as yet too small to enable effective population counts to be made.

The details of this work are being published elsewhere.

Entomological Aspects of 'Swollen Shoot' of Cacao

THE rapid spread of the deadly 'swollen shoot' disease of cacao first recorded by Steven[1] in 1936 justly gives cause for alarm. Now believed to be due to a virus transmitted by three species of insects of the family Pseudococcidæ, this malady of unknown origin bids fair to destroy the West African cacao industry. That this is realized by the people of West Africa is evident from the lively public interest in the problem.

It is not, therefore, too soon to pause and take stock of the problem. The good old-fashioned remedy of destroying affected trees and contacts, bearing as it does the stamp of common-sense, has won general support except, perhaps, from the unlettered farmer in whose egocentric view there is only one kind of dead cacao tree.

In this connexion it will be well to keep in mind the entomological aspect of the problem and see how the vectors may be controlled in the primitive conditions under which the crop is produced. One method which does not appear to have received the consideration it merits is that of biological control. In the welter of ideas about resistant varieties, immunization and cutting-out, this elementary aspect seems to have been forgotten. Yet the Pseudococcidæ are in some respects peculiarly amenable to this treatment in the tropics. In West Africa they are not heavily parasitized or preyed upon; and there is in other parts of the world a wide range of parasites and predaceous enemies which could be, possibly usefully, certainly with impunity, introduced into West Africa. I am not unaware of the provocative nature of this proposition. But those who would dismiss it untried should bear in mind the infinitesimal cost of effecting such introductions against the havoc wrought by the disease. No one can say whether the method will succeed. But it is a weapon that has proved itself elsewhere, and, in the present parlous state of the important West African cacao industry, it is one that should be tried without delay.

INTERNATIONAL UNION OF GEODESY AND GEOPHYSICS

THE Eighth General Assembly of the International Union of Geodesy and Geophysics, and of its seven constituent associations, was held at Oslo during August 19–28. The opening assembly, held in the large hall ('Aula') of the University of Oslo, was attended by the King of Norway and the Crown Prince. The Government of Norway and the municipality and the University of Oslo extended the most generous hospitality to the Union. A large amount of careful preparation had been done by the Norwegian Organising Committee under the chairmanship of Prof. H. Solberg, secretary of the Academy of Science and Letters.

Owing to the state of health of the president, Prof. Helland-Hansen, of Norway, the duties of president were carried out by the senior vice-president, Prof. N. E. Nörlund, of Denmark. The general secretary of the Union is Dr. J. M. Stagg, of the British Meteorological Office. The Council of the Union consists of one delegate from each country; the British member of the Council was Prof. J. Proudman. There were more than five hundred delegates and guests from about forty countries. The largest party was the British, numbering nearly eighty, of which about half were delegates appointed by the Royal Society; but the party from the United States exceeded seventy. This was the first ordinary General Assembly since the War; a small, purely administrative Assembly had been held at Cambridge in 1946, and this enabled the Oslo delegates to devote the maximum amount of time to scientific discussion. Evening lectures by Dr. M. A. Tuve, of Washington, and by Dr. S. Thorarinsson, of Iceland, the latter showing a remarkable colour film on the recent eruption of Mt. Hekla, were much appreciated. Prof. Vening Meinesz, of Holland, was elected president of the Union for the period 1948–51. An invitation from Belgium to hold the next General Assembly at Brussels in 1951 was gratefully accepted.

The Union expressed its gratitude for the very considerable financial assistance which it has received from Unesco. The major part of this has consisted of grants in aid of the permanent scientific services which are sponsored by the Union; the largest individual grant for 1948, £3,000, is in aid of the International Seismological Summary, the staff of which is housed at Kew Observatory. But many of the officers of the Union received Unesco grants in aid of their travelling expenses to and from Oslo.

A very valuable feature of the Assembly was the excursions, and it was on these that the warm-hearted hospitality of the Norwegians reached its height. It is the common experience of those attending international conferences that the personal contacts made on such excursions are, even from the point of view of the advancement of science, the most valuable part of the whole proceedings. Most delegates and guests accepted invitations to visit the district around Lillehammer on August 22. After the Assembly, forty delegates enjoyed a most entertaining and instructive visit to the hydro-electric works at Rjukan as the guests of Norsk Hydro. The meteorologists and oceanographers took part in excursions which met far up the Sogne Fjord, and from this point they were conveyed to Bergen in five research vessels, four of them Norwegian and one Scottish. The hospitality of the municipality of Bergen formed a fitting close to a memorable occasion.

Association of Geodesy. The work of the Association of Geodesy was distributed over five sections. In the Section on Triangulation there was much discussion on methods of measuring long distances, including triangulation between non-intervisible ground stations by radar and by the observation of flares dropped from aircraft. Consideration was also given to the proposal to extend the Central European Net to Western Europe. In the Section on Geodetic Levelling, deliberations were mainly devoted to refinements in the practice and theory of geodetic levelling and to the methods of research into those problems of tectonics on which levelling is capable of throwing light. The Section on Geodetic Astronomy gave consideration to co-operation with the International Unions of Astronomy and of Telecommunications. An interesting and important report on the activities of the Royal Observatory was received from the Astronomer Royal.

In the Section on Gravimetry it was noted that since 1939 the rapid development of static gravimeters has brought them into general use, not only for geodetic purposes but more especially for geological prospecting by oil companies. As a result, the quantity of gravity material accumulating in some areas is more than can be conveniently handled in geodetic work. It was decided that the Association should set up a Gravity Bureau. In the Section on the Geoid, attention was given to deviations of the vertical, to geoidal rise and deflexions, and to the application of methods of differential geometry to geoidal determination. There was a heated discussion on the 'co-geoid-fictitious level surface of the earth' after the removal of effects of compensated topography.

Both the president of the Association, Mr. W. D. Lambert, of Washington, and its secretary, Prof. P. Tardi, of Paris, were re-elected.

Association of Seismology. This Association benefited from the fact that a preliminary meeting had been held at Strasbourg in 1947. Without world-wide co-operation the progress of seismology would have been extremely slow. A notable example of such co-operation is the International Seismological Summary, for which the Association is responsible; significant measures for increasing the usefulness o the Summary were agreed upon at Oslo. A specia session of the Association was devoted to recent researches on the seismicity of the earth. One of the sessions was devoted to the study of the seismic results of the large explosions at Heligoland, Burton-on-Trent, Haslach and Soltau, and to the results o seismic prospecting in France, Spain and the United States.

The president, Dr. R. Stoneley, of Cambridge, and the secretary, Prof. J. Rothé, of Strasbourg, were re-elected.

Association of Meteorology. In his presidential address to the Association of Meteorology, Prof. S Chapman made a strong case for an Internationa Meteorological Research Organisation to link togethe the various meteorological research bodies throughou the world, and to serve as a clearing house for ideas. A strong impression was created by the discussion on rain-making by artificial means. Other important contributions included the following: a theory of selective unstable waves in an atmosphere described by the boundaries of the tropopause and the earth's surface, a subject which is connected with the formation of short-lived cyclones; fundamental problems in the study of radiation; the density of the high atmosphere as determined by the motion of meteorites; the need for more observations of water vapour and of helium in the high atmosphere; antarctic meteorology; jet streams; and the possibilities of statistical forecasting. Mr. A. W. Brewer exhibited an automatically controlled frost-point hygrometer, based on the design which he and Dr. Dobson had evolved, and gave an impressive account of the water vapour content above the tropopause. Prof. Byers showed a film exhibiting in slow motion the records of radar reflexion from rain during thunderstorms over Florida.

Prof. J. Bjerknes resigned the office of secretary and was elected president; Prof. J. van Mieghem was elected secretary.

Association of Terrestrial Magnetism and Electricity. The discussions of this Association included the following subjects: the influence of solar activity on terrestrial magnetism; air-borne magnetic surveys carried out in the United States and in Britain, which show great promise for the near future; the origin of the earth's magnetism; diurnal variation of the horizontal force near the magnetic equator; detection of rapidly moving ionic 'clouds', observed during ionospheric storms; and the use of $V2$ rockets for the exploration of the upper atmosphere.

Owing to the absence of the president, Dr. J. A. Fleming, of Washington, the chair at the early meetings was taken by Prof. J. Coulomb, of Paris; Prof. S. Chapman, of Oxford, was then elected president, and presided at the later meetings. The secretary, Dr. J. W. Joyce, of Washington, was re-elected.

Association of Physical Oceanography. A change of emphasis as compared with those at earlier Assemblies was shown in the meetings of the Association of Physical Oceanography. Previously, most attention was given to the distribution of temperature and salinity in the oceans and to the deductions regarding water-movements, etc., which could be drawn from such distributions. On this occasion, most attention was given to observations of oscillations in the sea, ncluding surface-waves; turbulence and storm-surges. The change reflects a result of the War, which prevented ocean-going expeditions and turned attention to problems associated with the landing of roops on beaches. For the first time, British oceanographers took a prominent part in the presentation of papers.

Most of the standing scientific committees of the Association, including those on mean sea-level, ocean bottom, weather ships and technical handbook, were reappointed, while a new one on bibliography was set up. The president, Prof. H. U. Sverdrup, of Oslo, was re-elected. Prof. J. Proudman, of Liverpool, esigned the secretaryship, and Prof. H. Mosby, of Bergen, was appointed to succeed him.

Association of Vulcanology. In the absence of the resident, Prof. Michel-Lévy, of Paris, owing to ill-health, the Association of Vulcanology met under the chairmanship of one of the vice-presidents, Prof. B. G. Escher, of Leyden. His address was on the symmetrical shape of the earth's surface and its fect upon the volcanism of the earth and the moon. Contributions included reports dealing with volcanic activity during the past decade, in Japan, Kamchatka, the East Indian archipelago, Guatemala, the West Indies, Africa, Iceland, Etna, Vesuvius, and elsewhere. Few vulcanologists attended the meeting, which is largely to be ascribed to the coincidence in time of the International Geological Congress in London.

Two new objects were brought forward, and to these particular attention was given. A commission was set up under the chairmanship of Prof. L. Glangeaud for the purpose of studying the extinct volcanoes of the world with special reference to the relations between geological time and the changing composition of the magmas concerned. A long-standing policy of the Association, for which funds have been accumulated over a number of years, is the publication of a catalogue of the active volcanoes of the world, and a conference was held on the scope of the catalogue, and its compilation and publication. Prof. B. G. Escher, of Holland, was elected president, and Prof. F. Signore, of Italy, was re-elected as secretary.

Association of Hydrology. The work of the Association of Hydrology was spread among the four commissions: limnology, potamology, underground water, snow and glaciers. The Limnology Commission dealt with the balance-sheet of a lake, with statistics of lake-level and with the movement of water in lakes; the Potamology Commission with evaporation, with precipitation-recording methods, and with transport of solid material in Nature and in the laboratory; and the Underground Water Commission with infiltration, with variations of level in springs, and with hot springs in general.

The Commission on Snow and Glaciers, in addition to the set themes, dealt, *inter alia*, with suggested classifications of snow, and with the alternative methods of observation and reporting which are now in use in the United States and Switzerland. The report on glacier variations was the first to be made by the new permanent committee which was established at Washington in 1939 to carry on the work of the long-established Commission Internationale des Glaciers. The statistical data up to now have dealt solely with the changes of position of the glacier snouts; but in future it is planned to include three-dimensional surveys of selected glaciers. There was an exhibition of glaciological films. It was decided to reduce the number of commissions to three: underground water, lakes and rivers, snow and ice.

The Association met under the chairmanship of Prof. G. Slettenmark, of Sweden, who had been appointed acting president after the death in 1947 of Prof. O. Lütschg, of Switzerland. The secretary, Prof. F. Diénert, of France, died shortly afterwards, and his place was filled by Prof. A. M. Vibert, of France, as acting secretary. At the close of the Assembly, Mr. Merrill Bernhard, of the United States, was appointed president, and Prof. L. Tison, of Belgium, was appointed secretary.

A joint meeting of the Associations of Seismology, Meteorology and Physical Oceanography was devoted almost entirely to thirteen papers on microseisms, recent developments in this subject showing how profitable has been co-operation between workers in the different sciences. The Union Committee on Continental and Oceanic Structure was replaced by a Joint Inter-Association Committee on the Physics of the Earth's Interior. J. PROUDMAN

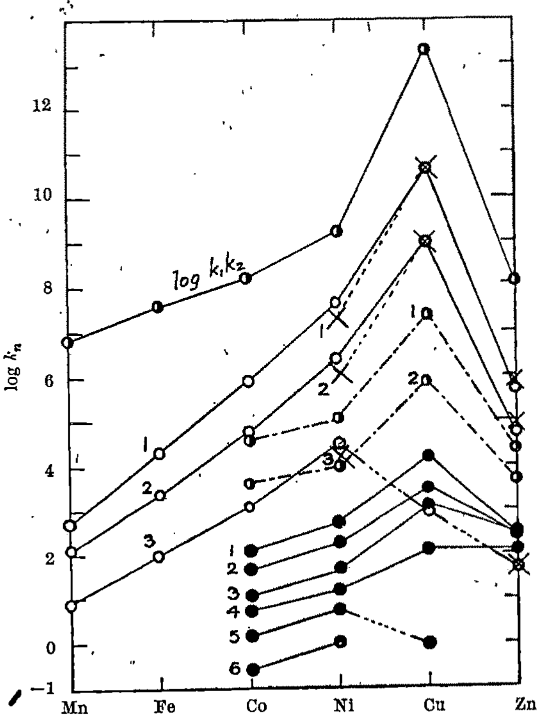
ORDER OF STABILITY OF METAL COMPLEXES

By DR. H. IRVING and R. J. P. WILLIAMS
Inorganic Chemistry Department, Oxford

MELLOR and Maley[1,2] have recently pointed out that the stability of complexes of bivalent metal ions follows the order

$$\mathrm{Pd} > \mathrm{Cu} > \mathrm{Ni} > \mathrm{Co} > \mathrm{Zn} > \mathrm{Cd} > \mathrm{Fe} > \mathrm{Mn} > \mathrm{Mg},$$

irrespective of the nature of the ligands involved, and remark that "although it is not clear what determines the order of metals in the series, it is worth noting that metals forming dsp_2 bonds ($\mathrm{Cu^{II}}$ and $\mathrm{Pd^{II}}$) head the list". Although our own programme of experimental work is incomplete, it appears desirable to indicate some of our conclusions in this field, since they extend the observations of Mellor and Maley and render to some extent more intelligible the order of decreasing stability found experimentally.



The numbers give the value of n in log k_n for: ●, ammonia; ○, ethylene diammine; ×, propylene diammine; ◐, salicylaldehyde.

If published data[2] on the successive stability constants of divalent ions of the first transition series are plotted against their atomic number (see graph), it is seen that the stability of complexes increases steadily to reach a maximum at copper whether the ligands be ammonia, ethylene diammine, propylene diammine or salicylaldehyde. The reluctance of copper to exceed a co-ordination number of 4 is shown by the low value of k_5 for the pentammino-, and k_3 for the tris-ethylenediammino-complexes. All zinc complexes are markedly less stable than those of $\mathrm{Cu^{II}}$, and it is perhaps significant that the M-shell is completely filled in $\mathrm{Zn^{II}}$, whereas the attachment of six groups through d_2sp_3 or dsp_2 orbitals (involving resonance) is possible throughout the sequence $\mathrm{Ca^{II}}$ to $\mathrm{Cu^{II}}$. A similar trend of stabilities can be noted in the second transition series with $\mathrm{Pd^{II}} > \mathrm{Cd^{II}}$, but the interposition of $\mathrm{Ag^{II}}$ (which forms complexes isomorphous with those of $\mathrm{Cu^{II}}$) can as yet be only inferred. In the third transition series, the order of stability is certainly $\mathrm{Pt^{II}} > \mathrm{Hg^{II}}$ and $\mathrm{Pb^{II}}$.

Published data on the *absolute* stability of complexes are limited so far to those already quoted. Yet it is obvious that the formation of an inner complex represented by the equation

$$M^{n+} + n\,\mathrm{H}R \rightleftharpoons MR_n + n\mathrm{H}^+$$

involves essentially a competition between (hydrated) protons and metal cations for the anion of the reagent forming the complex: the more stable the complex, the lower the pH at which it can persist, and *vice versa*. (It is, of course, implicit that any ligand displaces an equivalent number of water molecules from the hydrated cation; for example, ammonia or pyridine displace one; diammine salicylaldehyde or dithizone displace two, etc.) It can be shown that the pH for 50 per cent precipitation (or 50 per cent extraction of metal complexes for a constant excess of reagent) is a measure of their relative stability. Such data, with figures for the pH of incipient precipitation of metal quinaldinate and, for comparison, the stability constants of salicylaldehyde complexes are collected in the accompanying table and confirm the sequences of stability already noted.

Metal	'Oxine'; pH for 50% precipitation[3]	'Dithizone'; pH for 50% extraction with carbon tetrachloride[9]	Quinaldinic acid; pH for incipient precipitation[4]	Salicylaldehyde; log k_1k_2 in aqueous dioxane[1,2]
Mn	4·8	~9	—	6·8
Fe	—	5·6	—	7·6
Co	3·2	4·9	3·9	8·3
Ni	3·2	3·0	3·9	9·2
Cu	2·3	1·0	0·5	13·3
Zn	3·1	3·2	1·85	8·1
Pd	—	~−2·0	2·5	14·8
Cd	4·2	4·1	3·2	7·8
Pt	—	~−2·0	—	—
Hg	—	~−2·0	0·2	6·8
Pb	5·2	5·5	3·6	9·1

It is worth noting that among the divalent cations of the first transition series, copper alone is precipitated by 5:7-dibrom-8-hydroxyquinoline in normal acid[5], and similar examples of the outstanding stability of cupric complexes are commonplaces of analytical chemistry. H. Fischer[6] noted similar order of stability for complexes with α-nitroso β-naphthol, β-nitroso-α-naphthol and diphenyl carbazone, though the positions of cobalt and nickel were sometimes interchanged.

It must be emphasized that the order may be radically changed if the divalency of any of the participants is altered. Thus the selectivity of nitrosonaphthols as reagents for cobalt depends on their capacity to oxidize it and form a complex of trivalent cobalt far stabler than the corresponding complexes of divalent iron and nickel (or cobalt That divalent copper, palladium (and trivalent iron interfere with the cobalt test[7] shows that their complexes are comparable in stability, even with those of trivalent cobalt. Derangement of the 'natural' order of stability may also arise from steric and other factors. Thus, copper forms normal 1:2 complexes with M-methyl- and NN′-diethyl-ethylenediammine but cannot do so with N-methyl (or ethyl)-N′-diethyl ethylenediammine[8]; and trivalent gallium, indium and thallium, but not aluminium, will give insoluble 1 : 3 complexes with 2-methyl-8-hydroxyquinoline and similar rêagents[9]. We shall present elsewhere our observations with sterically hindered ligands such as α-methyl- and α : α′-dimethyl-*o*-phenanthroline.

The stability of complexes formed by any one ligand, for example, ammonia, with a series of metals may be expected to increase with the electronegativity of the metal concerned. Though reliable values for the transition elements are not yet available, it is of interest to record that a plot of instability constants (log k_n) against the second ionization potential (corresponding to the change $M \rightarrow M^{++} + 2e$ for the metal concerned) is approximately linear from manganese to copper, points for zinc lying somewhat off the curves. Thence, or less readily from the accompanying graph, it can be seen that the successive increments in stability in passing from manganese to copper complexes are of much the same order whether water is replaced by two molecules of ammonia, or one of salicylaldehyde or a diammine. When any one metal is considered, the gain in configurational entropy consequent upon ring formation is strikingly demonstrated by the high relative stability of the latter complexes.

Whereas it seems reasonably certain that the most stable complexes are always formed by elements erminating the transition series, and probable that he same 'natural' order of stability is preserved throughout each series, the acceptance of a unique order of stability operating throughout the Periodic Table must wait upon more extensive quantitative measurements with more varied types of ligands and upon a wider range of metals. Quantitative studies on chromous complexes should prove of particular interest.

FIRST INTERNATIONAL CONGRESS ON RHEOLOGY

SOON after the end of the War, the Committee of the British Rheologists' Club approached rheoogists in the Netherlands about the possibility of holding an International Rheological Congress in Holland. Dutch rheologists welcomed the suggestion nd set up a Committee to organise the Congress (see *Nature* of January 17, 1948, p. 104).

Shortly afterwards, the International Council of Scientific Unions appointed a Joint Committee on Rheology which held its first meeting in London in September 1947. The honorary secretary, Prof. J. M. Burgers, was taking a leading part in the organisation of the Congress, and it was agreed that he plans for the Congress should be made in close o-operation with the Joint Committee, the second annual meeting of which would also be held at the same date and place as the Congress itself. The Congress was held at Scheveningen during September 0–25.

The technical business of the Congress was divided into two parts: (1) general lectures given by invitation of the Committee; (2) shorter communications submitted by members. The latter part was arranged to run in three concurrent programmes, though the subject-matter was grouped in four categories: (*a*) theoretical problems; (*b*) experimental methods; (*c*) rheological properties of various systems; (*d*) biological systems.

The official languages of the Conference were English and French, the Dutch members showing a remarkable proficiency in the English language.

There was also a general discussion on nomenclature introduced in a general lecture by Prof. J. M. Burgers, who also presented a communication from the International Joint Committee. The Joint Committee had instructed two of its members, Prof. J. M. Burgers and Dr. G. W. Scott Blair, to draw up a report on nomenclature based on the various wartime publications of the British Rheologists' Club and of Dutch rheological organisations. Although developed entirely independently of one another, these reports had been found to have very much in common.

Prof. Burgers also summarized in his address the general scope of the work which the Congress was about to undertake.

The general lectures covered a wide field of rheology. Prof. F. Eirich, of the Polytechnic Institute of Brooklyn, N.Y., dealt with experimental methods in rheology, discussing the relative merits of different types of viscometers and rheometers for industrial and academic problems. Prof. C. Sadron, of the University of Strasbourg, spoke on the viscosity of dilute solutions of macromolecules, with special reference to molecular shape and orientation. This lecture was particularly valuable in drawing together information from Dutch, American, British and French sources, and in presenting a composite picture of the complex problems of viscosity-concentration relations.

Dr. M. Reiner, of the Technical College, Haifa, spoke on rheological relations in complex systems, outlining first the applications of the classical theories of elasticity and hydrodynamics, and then proceeding to discuss how the classical rheological coefficients vary with structural changes in the material and how various groupings of elastic and viscous elements are linked together to account for the behaviour of complex systems. Dr. K. Weissenberg, of the British Rayon Research Association, Manchester, also spoke on rheology of abnormal systems, developing a comprehensive scheme by which all macroscopic aspects of rheological behaviour can be dealt with whether previously regarded as 'normal' (that is, conforming to some established theory or convention) or as 'abnormal'. The scheme is based on a general theory of transformation for defining invariant rheological parameters. The lecture was ably illustrated by experiments.

Dr. G. W. Scott Blair (University of Reading) discussed psychophysical aspects of rheology, and the relationship between physical measurements and subjective judgments of rheological conditions as made by craftsmen in industry, and explored the possibilities of applying multiple factorial analysis to data from batteries of empirical rheological tests. Prof. A. L. Copley (New York University) spoke on biological problems in rheology, dealing especially with rheological problems of protoplasm, of cellular coats and intercellular substances, and on the rheology of body fluids ('humoral rheology'). Dr. R. Houwink, of the Rubber-Stichting, Delft, who was also chief secretary of the Congress, spoke on rheology in industry, outlining the main rheological properties important for industry, with special reference to glass, asphaltic bitumen, thermoplastics, thermosetting plastics and paints.

In a short account of the Congress it is impossible to deal with all the contributions to the sectional meetings, numbering between thirty and forty papers; but it can be said that the ground covered was very wide.

There were a number of papers on thixotropy, including one by Sir Charles Goodeve, in which a novel model was described to represent thixotropic and plastic flow. Dr. H. Nitschmann, from the Harvard Medical School, Boston, described interesting experiments on thread-forming liquids, showing the relationship between this property and changes in viscosity with driving pressure. Dr. C. N. Davies, of the London School of Hygiene and Tropical Medicine, also discussed thread formation of liquids. It was somewhat unfortunate that, in an otherwise admirably arranged programme, Drs. Davies' and Nitschmann's papers were read in different sections almost simultaneously. M. M. Louis (Reuil, France) described a new type of viscometer for industrial use which should have a wide appeal on account of its simplicity of design; and a number of new rheometers were also described for the study of rubber, plastics, printing inks and other materials. Drs. H. de Bruijn and P. G. Meerman, of the Netherlands State Mines, discussed the use of a Stormer viscometer for settling suspensions, and Mr. W. Lethersich, of the Electrical Research Association, the relative merits of compression and rotation instruments for work on dielectrics.

On the theoretical side, turbulence phenomena received considerable attention; Dr. R. Schnurmann, of the Manchester Oil Refining Co., dealt with Reynolds' numbers in solutions of large molecules, and Dr. J. C. Oldroyd (Courtaulds, Ltd., Maidenhead) discussed wall-effects in turbulent flow through pipes. Prof. J. J. Hermans (University of Groningen) gave a summary of his well-known work and that of Prof. P. H. Hermans on swelling of gels, and Prof. W. T. Astbury (Leeds) gave an account of X-ray and electron microscope studies on myosin and actin.

Of the thirty-eight sectional papers, apart from general lectures, circulated in preprint form before the meeting, no less than twenty were from British rheologists, and, indeed, Great Britain was very well represented at the Congress.

An exhibition of rheological apparatus included instruments from Holland, Great Britain and France. The apparatus was classified in accordance with the way in which the stresses are applied, for example, direct, alternating, etc., whether the stress is distributed homogeneously throughout the material, or inhomogeneously, and whether the rates of shear are constant or variable. There were some sixty instruments grouped in this way. The exhibition was open during most of the Congress, and Dr. R. N. J. Saal gave a short informal address describing the exhibits and their classification.

On the evening of September 23 an informal dinner was held, Prof. H. R. Kruyt presiding. Prof. Kruyt proposed the health of the delegates, and replies were made on behalf of Great Britain by Dr. G. W. Scott Blair, of the Continental countries by Prof. C. Sadron and of the United States by Dr. A Voet.

Following the Congress, many delegates took par in a three-day trip by touring car to Arnhem an the State Mines in the Province of Limburg. O September 25 visits were paid to the General Rayo Union, to the Staple Fibre Factory of the A.K.U. to the Netherlands Shipbuilding Experimenta Station at Wageningen and to the Central Foo Products Research Station. On September 26 ther was a visit to the Arnhem Battlefield and on September 27 to the Central Experimental Station of Stat Mines at Treebeck.

The Congress was very well organised, although in spite of the quite remarkable recovery already made, conditions in Holland are at least as difficul as they are in Britain. The Dutch organising committee must have worked extremely hard in preparin the Congress, and the unfailing kindness and hel which we received from all our Netherlands colleagues, and especially from Prof. J. M. Burger (chairman), Dr. R. Houwink (first secretary) an Dr. G. E. Rotgans (organising secretary), will lon be remembered. (As Dr. Houwink said at the dinner Dr. Rotgans turned out to be "not a bad goose, bu a very good goose indeed !")

Although in existing circumstances it was felt t be unwise to fix a date and place for the Secon Congress, it was the general feeling both in th Congress itself and within the International Join Committee that congresses of this kind should b held about every four years, and the hope wa expressed that the Joint Committee should recommend the calling of a Second Congress in due course

The *Proceedings* of the First Congress will b published shortly and will be available at an approximate cost of £2 8s. G. W. SCOTT BLAIR

NATIONAL RESEARCH COUNCIL OF CANADA

ANNUAL REPORT

THE thirty-first annual report of the Nationa Research Council of Canada (Ottawa) covers th year ended March 31, 1948, and includes the repor of the president, Dr. C. J. Mackenzie, together wit the financial statement. The total expenditure durin the year amounted to just over 6·9 million dollars almost a further quarter of a million dollars wa expended on work carried out at the request o Government Departments and provided for by them apart from the 7·646 million dollars received in othe ways, including parliamentary appropriations o 6·351 million dollars. To cope with the expandin programme, facilities have been extended and th staff now total more than 2,300, of whom a thousand half of them scientific workers, are working a the atomic energy project at Chalk River. Th operating branch for the production and extractio of isotopes was organised during 1947, and branche of the project are concerned with the problems o operating the low-energy ZEEP and the higher powered experimental NRX piles and handling thei highly radioactive products safely and effectively Attempts are being made to spread the new techniques and knowledge to the universities and othe research institutions in Canada, and thus to foste research in these fields.

A new Division of Radio and Electrical Engineering has been established and substantial progress made in the applications of radar. In harbour control a nine-inch display with accurate ranging facilities has been added to the original installation at the Naval Signal Station at Camperdown, Nova Scotia, and procedures are being worked out for the use of shore-based radar in the identification and guidance of incoming ships that are not equipped with radar. Trials during the past season have shown that blind navigation of the entrances of Toronto Harbour and identification of every wharf within the Harbour is possible. The practical value of a direct-reading electronic instrument for locating hot joints on power ines has been demonstrated in field tests.

The Division of Physics carried out magnetometer surveys during the latter part of the year in co-operation with the Department of Mines and Resources and with the assistance of the Royal Canadian Air Force. A fundamental investigation has been started on the nature and source of cosmic rays, in particular their relation to other geophysical phenomena such as magnetic storms, and the ionosphere. A high-speed cine-camera capable of operating at a rate of 200,000 frames per second has been designed and built, and a method of geophysical prospecting has been tried in which measurements are made of the depth of overburden by vertical echo-ranging from the surface, and exploraion within the bed-rock, with a device which is dropped down a drill-bed. Architectural studies include a series of commercial sound-absorption tests, while equipment has been completed for producing high-intensity sound fields at frequencies from four kilocycles to about 600 kilocycles per second, and a new rod thermostat is being developed for use in railway refrigerator cars. A summer programme of panel-cooling investigations in two experimental houses was undertaken and continued through July and August 1947, while photographic research included work on the aerial camera, the dimensional tability of photographic film bases and the factors affecting the rendering of detail in contact printing.

The organisation of the Pure Chemistry Branch has been completed, and an infra-red spectrometer installed in the section on organic spectrochemistry. Among many problems investigated in the Applied Chemistry Branch of the Division of Chemistry are he lubrication of railway car journal bearings, the correlation of laboratory abrasion tests with actual oad tyre tests, the laundry application of dust-laying oils to cotton and wool hospital fabrics, corrosion inhibitors for use in various types of olution and the spreading of oil paints on certain repellent surfaces. A co-operative research with the Noranda Mines, Ltd., promises to develop a method of roasting pyrites for the recovery of elemental sulphur, and the investigation of silver alloys as catalysts for the oxidation of ethylene to ethylene oxide with air has led to the development of highly ctive stable catalysts. A method has been developed or the rapid determination of low concentrations of arbon monoxide in air.

Much of the work of the aeronautics section of the Division of Mechanical Engineering is devoted to wind-tunnel testing of new aircraft designs for Canadian firms; the low-temperature laboratory continued the flight investigation of aircraft icing, lectro-thermal de-icing for wings and propellers and he study of meteorological conditions associated with ice. A snow-cover survey was initiated, in co-operation with the Meteorological Service of the Department of Transport, to obtain data on the type and condition of snow encountered in different parts of Canada, in order to assist in developing snow-clearing equipment and in the study of such subjects as aircraft skis. Work continued on the improvement of fuels and lubricants for use at low temperatures, and research was initiated on fuels and combustion in jet engines.

In the Division of Applied Biology, substantial progress was made in research on food preservation and the industrial utilization of agricultural wastes and surpluses. Investigations on oiling, antiseptic and gas treatment of shell eggs have facilitated shipments to Britain, and transport temperatures have been established for a milder and more acceptable bacon. Extensive work has indicated that the Fritz machine for continuous butter production, as designed for German use, cannot consistently produce butter meeting the Canadian legal standard of not more than 16 per cent moisture content. Laboratory studies on new cooling mixtures to provide lower temperatures in refrigerated railways cars gave promising results, and a study has been commenced on the fermentation of cellulose wastes, while that on the fermentation of beet molasses has reached the pilot-plant stage. Work was also commenced on the utilization of straw.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, November 8

INSTITUTION OF POST OFFICE ELECTRICAL ENGINEERS (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 5 p.m.—Mr. W. J. Bray: "The Possibilities of Super H.F. Radio and Wave-guide Systems for Telecommunications".

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 5 p.m.—Prof. G. H. J. Daysh: "Development Areas and the Location of Industry".

Tuesday, November 9

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Mr. A. L. Armstrong and Prof. H. J. Fleure, F.R.S.: "Discovery of a Palæolithic Skull in a Rock Shelter at Whaley, near Creswell, Derbyshire".

ZOOLOGICAL SOCIETY OF LONDON (at the Zoological Gardens, Regent's Park, London, N.W.8), at 5 p.m.—Scientific Papers.

INSTITUTE OF PHYSICS, ELECTRONICS GROUP (at 47 Belgrave Square, London, S.W.1), at 5.30 p.m.—Mr. P. H. Flanders: "The Physical Properties of Very High Voltage X-Rays and Electrons and their Medical Benefit".

INSTITUTION OF ELECTRICAL ENGINEERS, RADIO SECTION (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Continuation of the Discussion on "To What Extent does Distortion Really Matter in the Transmission of Speech and Music?" (to be opened by Mr. P. P. Eckersley).

SOCIETY OF CHEMICAL INDUSTRY, CHEMICAL ENGINEERING GROUP (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. A. D. Davidson: "Heat Transfer".

ILLUMINATING ENGINEERING SOCIETY (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 6 p.m.—Dr. J. W. Mitchell: "High Speed Photography".

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Discussion on "Rubber as a Stress-Carrying Material, and some Design Considerations" (to be opened by Mr. S. W. Marsh).

SIR HALLEY STEWART TRUST LECTURE (at the Memorial Hall, Farringdon Street, London, E.C.4), at 6 p.m.—Mr. R. F. Harrod: "The Atomic Age—The Economic Repercussions of Atomic Power".*

MANCHESTER GEOGRAPHICAL SOCIETY (in the Geographical Hall, St. Mary's Parsonage, Manchester), at 6.30 p.m.—Rev. Brian L. Gandon: "Through India to the Himalayas".

TEXTILE INSTITUTE, YORKSHIRE SECTION (at the Midland Hotel, Bradford), at 7 p.m.—Mr. W. H. Hillier: "The Treatment of Sewage containing Textile Effluent".

Wednesday, November 10

PHYSICAL SOCIETY, COLOUR GROUP (at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 3.30 p.m.—Scientific Papers.

Institute of Petroleum (at Manson House, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. F. H. Garner and Mr. A. R. W. Baddeley: "Detergency of Carbon Black in Hydrocarbon Solution".

Institution of Electrical Engineers, Supply Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. H. M. Lacey: "The Lightning Protection of High-Voltage Transmission and Distribution Systems".

Royal Institute of Chemistry, Newcastle-upon-Tyne and North-East Coast Section (at King's College, Newcastle-upon-Tyne), at 6.30 p.m.—Dr. L. H. Lampitt: "Food Problems".

Thursday, November 11

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. H. Dingle: "What is Science?"*

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. R. M. Goody: "Thermal Equilibrium at the Tropopause and the Temperature of the Lower Stratosphere"; Prof. S. Chapman, F.R.S., and Mr. K. K. Tschu: "The Lunar Atmospheric Tide at 27 Stations widely distributed over the Globe".

University of London (in the Department of Biochemistry, University College, Gower Street, London, W.C.1), at 4.45 p.m.—Dr. B. C. J. G. Knight: "Biosynthesis in Micro-Organisms".* (Further lectures on November 18 and 25.)

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. R. J. Smeed: "Some Statistical Aspects of Road Safety Research".

Illuminating Engineering Society, Manchester Centre (joint meeting with the Association of Public Lighting Engineers, in the Reynolds Hall, College of Technology, Manchester), at 6 p.m.—Mr. W. D. Sinclair: "Fluorescent Street Lighting".

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—M. Destival: "French Aircraft Gas Turbines".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7 p.m.—Prof. C. E. H. Bawn: "The Structure and Reactivity of Free Radicals" (Tilden Lecture). (To be repeated on Friday, November 19, at the University, Glasgow.)

Institute of Metals (at the Royal School of Mines, South Kensington, London, S.W.7), at 7 p.m.—Prof. W. R. Jones: "Resources of Strategic Metals".

Pharmaceutical Society, Manchester, Salford and District Branch (joint meeting with the National Association of Women Pharmacists, in the Lecture Theatre, St. Mary's Hospital, Manchester), at 7.45 p.m.—Mr. D. G. Ardley: "Some Recent Advances in Drug Therapy".

Wednesday, November 10—Thursday, November 11

Iron and Steel Institute (at 4 Grosvenor Gardens, London, S.W.1).—Autumn Meeting.

Friday, November 12

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Institution of Mechanical Engineers, Applied Mechanics Group (at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Discussion on "Some Properties of the Compression Shock as in Turbine and Compressor Blade Passages" (to be opened by Mr. I. M. Davidson).

North-East Coast Institution of Engineers and Shipbuilders (at the Mining Institute, Newcastle-upon-Tyne), at 6.15 p.m.—Mr. R. G. Voysey: "Techniques of a Gas Turbine Vibration Laboratory".

Oil and Colour Chemists' Association, Manchester Centre (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Dr. D. R. Duncan: "The Colour of Pigment Mixtures".

Saturday, November 13

British Psychological Society (at Tavistock House, Tavistock Square, London, W.C.1), at 2.30 p.m.—Discussion on "Current Professional Problems of Psychologists" (to be opened by Miss Grace Rawlings and Mr. Alec Rodger).

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 2.30 p.m.—Major Maxwell Knight: "The Habits and Lives of British Reptiles and Amphibia".*

Royal Institute of Chemistry, London and South-Eastern Counties Section (at the University, Reading), at 3 p.m.—Symposium on "Radioactive Tracer Elements".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Educational Psychologist—The Director of Education, County Education Office, St. Mary's Gate, Derby (November 13).

Senior Research appointment to be made for the purpose of undertaking Government-sponsored research into problems of the location of industry—The Secretary, National Institute of Economic and Social Research, 2 Dean Trench Street, London, S.W.1 (November 13).

Head of the Science Department of the Technical College of Monmouthshire, Crumlin—The Director of Education, County Hall, Newport, Mon. (November 13).

Lecturer in Mathematics in the Physics and Mathematics Department—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham, Essex (November 13).

Chief Laboratory Engineer to take charge of a recently established Highways Laboratory at Osset, near Wakefield—The County Engineer and Surveyor, County Hall, Wakefield (November 13).

Educational Psychologist—The Director of Education, Education Offices, Cobourg Street, Plymouth (November 15).

Lecturer in Pure Mathematics in the School of Science, Gordon Memorial College, Khartoum—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (November 15).

Veterinary Surgeons (6), and a Field and Research Officer, in the Department of Veterinary Services, Southern Rhodesia—The Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (November 19).

Head of the School of Applied Chemistry, Melbourne Technical College—Mr. S. L. Martin, Mathematics Department, University College, Gower Street, London, W.C.1 (November 19).

Lecturer in the Department of Physics—The Registrar, University College, Hull (November 20).

Educational Psychologist—The Secretary for Education, County Buildings, Shrewsbury (November 22).

Officer-in-Charge of the Tests Division—The Director, National Foundation for Educational Research, 79 Wimpole Street, London, W.1 (November 22).

Lecturer or Assistant Lecturer in the Department of Biochemistry—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2 (November 24).

Lecturer in Physiology in University College, Dundee—The Secretary, The University, St. Andrews (November 30).

Leverhulme Studentship in Chemical Engineering—The Registrar, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7 (November 30).

Lecturer or Assistant Lecturer in the Department of Electrical Engineering—The Registrar, The University, Sheffield (December 1).

Meteorological Officer Cadets (5) in the Department of Industry and Commerce—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin (December 10).

Museums Assistant, primarily to supervise the collections in the Kirkstall Abbey House Museum (devoted to local history and antiquities)—The Director, City Museum, Park Row, Leeds (December 20).

Transvaal Chamber of Mines Chair of Wood Technology in the University of Stellenbosch—The Secretary, South Africa House, Trafalgar Square, London, W.C.2 (Stellenbosch, December 31).

Senior Assistant in Chemistry—The Registrar, College of Technology, The Newarke, Leicester.

Senior Geologist to the Government of the Gold Coast to undertake general geological work including geological mapping and prospecting—The Director of Recruitment, Colonial Service, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Lecturer in Biology, and a Lecturer in Chemistry—The Principal, Derby Technical College, Normanton Road, Derby.

Abstractors (part-time) for the *Veterinary Bulletin*—The Director Commonwealth Bureau of Animal Health, Veterinary Laboratory New Haw, Weybridge, Surrey.

Lecturer in the Department of Applied Chemistry—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1

Deputy Executive Officer, and a Technical Officer in Seed Production—The Secretary, National Institute of Agricultural Botany Huntingdon Road, Cambridge.

Laboratory Technician in the Department of Pathology—The Pathologist, Royal Devon and Exeter Hospital, Exeter.

Scientific Officers (2) in the Biochemical Department for work on the separation and characterization of large molecules of biological origin—The Secretary, Rothamsted Experimental Station Harpenden, Herts.

Senior Technician (male) for training for maintenance of X-Ray Geiger counter and other equipment in the Medical Research Council's Field Research Station at Fajara, Gambia—The Director, Human Nutrition Research Unit, National Hospital, Queen Square, London W.C.1.

Senior Scientific Officers and Scientific Officers, and Experimental Officers and Assistant Experimental Officers, a Chemical Engineers in the Ministry of Supply research and development establishments in Lancashire, Essex, Kent and Buckinghamshire—The Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.884/48A.

Assistant Inspecting Officers (Scientific Supplies), and Assistant Chemists (Grade III)—The Director-General, India Store Department (Inspection Branch), 32–44 Edgware Road, London, W.2.

Physicist for fundamental work on the structure and propertie of fibrous materials, etc., and a Physicist for laboratory and service test of shoes and shoe materials, etc.—The Director, British Boot Shoe and Allied Trades Research Association, Satra House, Rockingham Road, Kettering.

Senior Trained Biochemical Technician in the Physiology Department—The Professor of Physiology, King's College, Newcastle upon-Tyne.

Senior Physics Laboratory Steward—The Principal, Acton Technical College, High Street, London, W.3, quoting F.41.N.

Demonstrator in Parasitology in the Department of Pathology and Laboratory Technicians for (*a*) the Department of Physiology (for biochemistry), and (*b*) the Division of Histology and Embryology—The Secretary, Royal Veterinary College and Hospital, Royal Colleg Street, London, N.W.1.

Chemist to take charge of the research work (at present being carried out at Leeds University)—The Secretary, British Brush Manufacturers' Research Association, 80 Coleman Street, London, E.C.2.

Technicians (2, Grade III) in the Department of Botany—The Secretary, University College, Gower Street, London, W.C.1, quoting Botany/1.

Senior Lecturer in Agriculture responsible for Extra-mural Teaching—The Principal, Kent Farm Institute, Sittingbourne.

Biochemist (man or woman) preferably with post-graduate experience in the field of enzymes or tissue-metabolism—The Secretary Courtauld Institute of Biochemistry, Middlesex Hospital Medical School, London, W.1.

PHYSICAL SCIENCE AND HUMAN VALUES

In 1946, Princeton University celebrated its bicentenary by a number of conferences at which leading figures in the world of learning met to discuss progress in their particular fields. One of the groups which met in this way consisted of physicists, and on the first and third days of this gathering the topic for discussion was the relationship of physical science and human values—a welcome recognition that both can influence profoundly the work of a university. The papers read at the conference have now been published in book form*.

The papers themselves, as Prof. E. P. Wigner points out in his preface, fall into two groups: those concerned broadly with the way in which the organisation of the society of which the man of science is a member can influence the growth and the trend of science, and those concerned with the influence of the man of science and his work and thought upon that society. The distinction is not sharply drawn, the field covered is very wide, and more than a title is needed to give unity between such diverse themes as Mr. F. T. Spaulding's discussion of scholarship in the secondary school, Dr. L. A. DuBridge on the large laboratory in nuclear research, Prof. F. S. C. Northrop on the physical sciences, philosophy and human values, and Prof. P. W. Bridgman on new vistas for intelligence.

The common bond is to be found rather in the evidence which the book provides that physical scientists are thinking, and thinking deeply, about all the interactions of science and society. The British reader will note that American thought runs on very similar lines to that of men of science in Britain; and the book, with Prof. H. N. Russell's approval, in the concluding paper, of the suggestion that a new Hippocratic code is needed to-day for all who deal with nuclear energy, and that the powers of life and death which are in our hands must be used soberly, and so far as in us lies, in the fear of God, supports the recent statement issued by the Committee on Science and its Social Relations set up by the International Council of Scientific Unions (see *Nature*, October 2, p. 507).

The papers in this volume, which cover subjects like the relation of research in universities to government and commercial laboratories, seldom contribute anything very novel; but points are stressed which are commonly overlooked or ignored in current debate in Britain. There is the same concern lest the university laboratories should be diverted from the advancement of science to the solving of commercial problems. In the United States, as in Britain, that would be regarded as a disaster of the first magnitude, and Dr. I. I. Rabi's suggestion that in the university research is to some extent secondary to, or parasitic on, teaching, at once drew the counter-attack that the advancement of knowledge is the first function of a university and that industry is really dependent upon the universities. Nevertheless, while industry's dependence not only upon new knowledge but also upon the development of new technologies was recognized, there was not in this discussion any tendency to exalt the divergent research typical of the university at the expense of the convergent research in industry. Both are required, and each would suffer if the other were cramped. The emphasis was rather on the need for co-operation, the way in which industry reacts on science, science on industry, and also one science on another, providing the means whereby advances are made in other fields.

---

* Physical Science and Human Values. A Symposium by P. W. Bridgman, F. S. C. Northrop, H. Shapley, I. I. Rabi, H. N. Russell, M. Polanyi, F. T. Spaulding and L. A. DuBridge. With a Foreword by E. P. Wigner. Pp. vii+181. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1947.) 16*s*. net.

What stands out from the discussion is the recognition that the conditions favouring creative work are essentially the same in industry and in the universities, and that the spirit of freedom which enables an individual to work by his own method will become increasingly characteristic of the industrial research laboratory, as it already is of the university laboratory. Again, Dr. DuBridge stresses that the dominating factor in any research laboratory is the attitude of the workers themselves; and he points out rightly that without the tremendous emotional stimulus to co-operative effort which the War provided, any laboratory built along the lines of the large war laboratories is bound to collapse. The point is one to be kept in mind in considering the possibilities of applying what is known as the technique of operational research in peace-time. The question of incentives has as yet not received anything like the attention it merits where the man of science is concerned, and Dr. DuBridge's paper should stimulate further thought about the question and the psychological conditions conducive to collaboration in creative work. His confidence that the essential freedom of inquiry and time for thought can be secured even in the presence of great new techniques of physical science and organisation presents a challenge which the conference was not slow to meet, and Prof. M. Polanyi directed attention in this connexion to the importance of public opinion. Where public opinion respects the autonomy of science and the freedom of those charged with scientific work, he believes that the form of organisation matters little.

Another important factor is that to which Prof. Wigner directed attention, namely, the value of mobility and interchange of scientific staff, which is commonly recognized, but still rather the exception. Prof. Wigner suggested that in large institutions a reasonably rapid turnover of the personnel both at the top and at the bottom might well help to foster the sense of adventure and the lively atmosphere which is one of the big advantages of the university. Dr. Harlow Shapley's paper on the uses and hopes of scientific societies is of interest as indicating the way in which learned and professional societies could both counter the tendency to specialization and assist in the formulation of national policy. As an example of inter-science activity, he referred to the Society of the Sigma Xi; but he looked further to the Science Division of the United Nations Educational, Scientific and Cultural Organisation, urging especially th foundation by that body of great internation institutions for scientific exploration and develo ment in those fields where research is normally expensive that small institutions or even sma countries cannot easily undertake them on a nation basis, and also the establishment and operation travelling panels, each composed of specialists different nationalities and adjacent fields of specia ization.

When the conference entered upon the influence science on society, its thought was vaguer and le constructive. Prof. Northrop emphasized that if th atomic bomb was ever used to destroy civilizatio it would be because men could not get togeth sufficiently, on account of their ideologies, to agre upon the social controls that are necessary to me the situation. Although he argued that the ideologic conflicts between different conceptions of econom and political theory and human values are due t philosophical differences connected with scientif theory concerning Nature and the methods scientific verification in natural science, he did n entirely convince the conference as to the prob ability of a philosophical basis of agreement betwee the U.S.S.R. and the Western democracies; and suc scepticism will be encouraged by the recent fulsom adulation of 'Michurin science'. Science may we provide a rational basis for ethics; but it is the metho rather than the content which, as Prof. H. Margena suggests, forms the link; and in these latest man festations Russia appears to reject the values both science and of ethics, and to undermine the coheren which Polanyi regards as the real basis of freedom i science.

Doubtless greater precision in the choice of wor used to describe situations could remove so common and potent causes of conflict; but nothi in this symposium of papers warrants any optimis regarding the clash between the U.S.S.R. and t West. Admittedly it is imperative that other effecti controls shall be evolved in such fields as that nuclear energy before those imposed by milita security are relaxed, and these papers shatter a false ideas of absolute and irresponsible freedom work or communication for the individual scienti worker. Equally they make it manifest that t rejection by the U.S.S.R. of the tradition and di cipline of science at all points where they confli with a particular political ideology betokens difference in values which makes almost impossib at present her participation in the elaboration of t controls necessary to safeguard society. Where t transcendent character of scientific objective whi recognizes no limitations or national boundaries not admitted, there can be no such co-operatio Indeed, the dominant impression left by these pape is that the scientific workers of those countries which scientific values are respected must the selves elaborate the means by which the world c safeguard itself to-day, hoping that the task education and persuasion will secure the acceptan by others of those values in time to avoid catastrophe.

CYTOLOGICAL RESEARCH AND BIOPHYSICS

ubmicroscopic Morphology of Protoplasm and its Derivatives

y Prof. A. Frey-Wyssling. Translated by Prof. J. J. ermans and Miss M. Hollander. Pp. viii+255. ew York and Amsterdam: Elsevier Publishing o., Inc.; London: Cleaver-Hume Press, Ltd., 948.) 32*s*. 6*d*.

THE second edition of Prof. Frey-Wyssling's book is, as would be expected, a most stimulating ork. It comprises three sections. The first is conrned with methods for investigating submicroscopic orphology, such as X-radiation, polarized light, d electron microscope techniques. The second ters into numerous aspects of our knowledge of ll structure. The third covers structures such as llulose and keratin, and some of their relationships ith the cells which give rise to them. All this is ry much from Prof. Frey-Wyssling's own point of iew, expressed clearly and vigorously. It is much be regretted that the standard of translation from e German lacks literary quality: the sentence nstruction is awkward and the volume is lavishly attered with words not hitherto found in the nglish language. Although these defects never de the author's meaning completely, they do mper an appreciation of his clear flow of ought.

One of the main themes is the extent to which the operties of cells and their constituent parts are termined by elongated molecules and particles. is suggested that even the properties of the more id part of protoplasm are to be explained in terms the presence of such bodies, and the perpetual rmation and breakdown of junctions between em. This is a point of view which can scarcely be cepted with the scanty evidence we have availle; and on many, if not most, of the problems udied more views exist than are given in this ok. But it is a point of view worthy of its able ponent.

There is comparatively little discussion of the role long-range forces in the cell, though for the type system emphasized these forces are likely to be great importance. The forces acting between romosomes in meiosis and mitosis present one treme case, in which the distance over which the rces appear to act is of the order of micra, whereas tween small protein molecules the critical distances e of the order of millimicra. One of the major fficulties in advancing our knowledge of cells is our ck of understanding of the nature of the forces hich are important over distances of those orders magnitude. Thus the type of investigation which particularly suggested by this book is likely to be ought to a stop unless there are marked advances this branch of biophysics. The same is true of her branches of cytology: cell permeability awaits more adequate physical theory of diffusion; cell ctrophysiology depends upon a more detailed derstanding of thin films and membranes; cytoemistry waits upon advances in the field of optics, d so on.

The branches of physics which are involved are, the most part, those which are not of importance nuclear physics and electronics, which are attractg the lion's share of the interest and energies of physicists these days. It is thus more than ever necessary that departments of biophysics should be developed, which shall be sufficiently powerfully staffed to carry out fundamental research in those branches of physics and physical chemistry which are necessary for cytology. This policy has proved an outstanding success in the similar field of biochemistry; for example, the significance of phosphorylation and phosphorylation cycles, which ranks of the first importance in modern cell physiology, would never have been grasped had it not been for the existence of groups of biochemists capable of undertaking fundamental chemical investigations. One of the clearest conclusions to be drawn from Prof. Frey-Wyssling's book is that, without a rapid development of biophysics, a large part of cytological research must come to a halt, and much of biochemistry will be delayed in its application to cytology until the physical problems are solved.

J. DANIELLI

THE ENGINEER'S APPROACH TO ELECTRICITY AND MAGNETISM

Elements of Electrical Engineering

By Prof. Walter J. Creamer. Pp. ix+344. (New York and London: McGraw-Hill Book Co., Inc., 1948.) 24*s*.

THIS is an interesting and somewhat unusual type of introductory text-book to the study of electrical engineering. Its express purpose is to introduce the engineering approach to the study of electricity and magnetism to students already possessing an elementary knowledge of the mathematical and physical principles, and the scope of the book has been determined quite rigorously by this consideration. With one or two minor exceptions, only D.C. phenomena are treated; but the student is presumed to be aware of some of the general features of alternating current systems.

It is noteworthy that, as a result of this limitation of the field, many quite important matters not ordinarily dealt with in elementary text-books have found a place. For example, the star-delta transformation is treated in the chapter on the electric circuit, and the superposition principle is illustrated, although, oddly enough, it is not utilized in the demonstration of Thévenin's theorem. Chapter 3, on conductors and insulators, includes a paragraph on non-linear circuit elements. The measurement of ground resistance receives attention in the chapter on measuring networks, and electrolytic corrosion under electro-chemical principles. In the treatment of the magnetic circuit, trial and error methods are applied to the calculation of branched magnetic circuits.

Generally speaking, the material used to illustrate the engineering approach is judiciously chosen and well presented, and a satisfactory link is made with the underlying physical concepts. There are, however, examples of statements which might confuse rather than clarify the thoughts of the beginner. On page 9, for example, in relation to current density it is stated that "the distribution of current over the cross-section of a homogeneous conductor will not be uniform if the conductor lies close to another conductor carrying a large current", as though this were a phenomenon of significant magnitude on D.C.; then on page 187, in connexion with the calculation of the flux linkage of a coaxial cable, is the statement: "The component contributed by the current flowing in the outer conductor is difficult to derive, but it is usually so small that we may neglect it without serious error".

Although simple transient conditions in resistance-capacity circuits are treated in the chapter on the electric field, no reference is made to the effects of finite condenser leakage with series-connected condensers on D.C., and, in the reviewer's opinion, some qualitative consideration should have been given to changing electric displacement and the concept of displacement current. The chapter on electro-dynamic principles deliberately avoids all technological detail; but it might have been profitable to demonstrate qualitatively the effect of teeth and slots on flux configuration.

The final chapter gives a useful introduction to the elements of electron ballistics.

It is interesting to note that M.K.S. units are introduced in parallel with C.G.S. electromagnetic units.

The book contains an excellent set of problems to be worked by the student and is altogether a useful introductory text-book with many unusual features.

J. GREIG

HIGH-POWER PULSE GENERATORS

Pulse Generators

Edited by Prof. G. N. Glasoe and Asst. Prof. J. V. Lebacqz. (Massachusetts Institute of Technology: Radiation Laboratory Series, Vol. 5.) Pp. xiv+741. (New York and London: McGraw-Hill Book Co., Inc., 1948.) 54*s*.

THIS volume of the well-known Radiation Laboratory Series is primarily concerned with *high-power* pulse generators, or modulators as they are generally termed in Britain. The general policy with regard to this series has led inevitably to a concentration on American practice. This is not a defect, so long as the book is not taken to be a balanced, representative and historical account of the work of the Allies in the modulator field. Typical instances are: (*a*) A dismissal of mercury thyratrons in a few lines. No hint is given that the British were more successful in developing a 1·5-megawatt valve (C.V.12), and others which were standard in naval and other sets throughout the War. These valves will doubtless be replaced by hydrogen tubes—but they worked at the time. (*b*) The Americans during the War carried out a great deal of work on rotary spark-gaps, and the space devoted to these and to two-electrode enclosed gaps is again characteristic of their design practice rather than that in Britain. Air-blown three-electrode gaps, for example, are not mentioned, though the British naval 274/5 (1·5 MW.) main gunnery sets used a three-electrode air-blown gap.

Certain expressions used in the volume may be obscure to British readers; while 'bootstrap circuit' is now familiar, it is doubtful whether 'tailbiting circuit' is also clear, though it is certainly picturesque. There is also in this volume a certain amount of duplication and of omission which is perhaps a characteristic disadvantage of the symposium type of format. For example, one is surprised to fin in the section on measuring techniques no referenc to current-viewing transformers. For a brief trea ment of them one has to consult the section o pulse-transformers, where no assessment is made their merits compared with those of viewin resistances.

On the credit side of the book is a comprehensiv collation of those reports which showered on during the War from the United States, and th information in it will be indispensable, or a least invaluable, to anyone interested in generatin or transmitting discontinuities in voltage. F example, lengthy sections on the design procedu for pulse transformers, and the effect of puls transformer parameters on all kinds of circuits which they are employed, are the fruits of war-ti research and will now be useful in many differe fields. The inclusion of worked examples once aga makes one grateful for one feature of the editori policy in this series, which recognizes the importan of orders of magnitude to a correct understanding the subject. The name of Guillemin will always associated with the theory of line-type pulsers, and is satisfactory to find here a full account of h systematic treatment and classification of puls forming networks, which is now the basis of standard nomenclature in the United States.

The photographs reproduced in this volume a perhaps less good than in certain others of t series, but numerous oscillograms are reproduc and are very helpful. The general impression creat is one of comprehensiveness and competence, an the book is likely to be of a usefulness long o lasting its topical interest.

J. T. RANDALL

MECHANICS MINUS MATHEMATICS

Applied Engineering Mechanics

By Asst. Prof. Alfred Jensen. Pp. xi+316. (Ne York and London: McGraw-Hill Book Co., In 1947.) 3 dollars.

THIS book is intended for senior school studen and Dr. A. Jensen's aim has been to make it su able for those with little knowledge of mathemati The few integrals and differentials that appear a relegated to appendixes, where they reinforce t arguments in the text. The book teaches largely examples, of which there are a great many, so solved in ample detail and most having answe given. In addition, there are review questions a problems at intervals. The illustrations are pa ticularly clear, and there is good insistence througho on the use of sketches and diagrams. The stude too, is advised to check his work, and alternati methods of doing so are given. The examples a quite practical, so that the student can relate the to problems within his own experience.

The first part of the book is devoted to statics, a the thoughtful student may not entirely be convinc of the truth of the triangle of forces theorem the statement that forces, like velocities, are vecto and so can be added vectorially. The terms 'for and 'stress' are used for the same thing, thou 'stresses' are usually inferred to be the inter forces in a framework. Forces are classified in ystems depending on whether or not they are oplanar, concurrent or parallel; some emphasis on the unifying principles for dealing with any of these ystems would be advantageous. Three-dimensional orce systems are well treated and there is a good hapter on friction.

The second half of the book deals with dynamics, nd here the omission of elementary calculus results n some awkward circumlocutions. For example, on age 167 two "laws of motion diagrams" are formulated which are nothing more than the fundamental ifferential equations of linear motion shown more xplicitly in the appendixes. A slight knowledge of athematics would enable the student to grasp the ruth of these 'laws' without having to memorize hem parrot-wise. The distinction between mass and orce is made quite clear, mass being treated as a uantity derived from the more fundamental concept f force. Problems in dynamics are so far as possible educed to statics by the introduction of inertia orces and inertia couples. Here again the use of ree-body diagrams showing all the forces is urged on he student. In dealing with impulse and momentum would be as well to ensure that both these quantities re treated as vectors. The conservation of momentum equation given on page 292 is only true under ertain conditions; and a few examples showing solutions of momentum would be useful.

R. A. FOULKES

HUMAN ECOLOGY

uman Ecology

he Science of Social Adjustment. By Thomas obertson. Pp. xx + 534. (Glasgow: William aclellan (Publishers), Ltd., 1948.) 21s.

THE interest of men of science in the study of human relationships is growing apace, much to he benefit of sociology. Sociologists have in the ast been far too prone to assume that their subject an be developed in the library; social philosophy as steadily progressed as a result, while social ience, properly so called, has lagged behind.

Anyone interested in contemporary developments ill therefore welcome a book on "Human Ecology" hen he is informed by the dust-jacket that the uthor is "a physician who, after a distinguished niversity career in biological science and medicine, urned to the study of sociological problems". This a hopeful beginning, because it is the medical ofession which has made the most significant ntribution to the study of human relationships in cent years, as is evidenced by the work of psychiatrists in the Armed Forces during the War, and in e Tavistock Institute of Human Relationships and milar bodies more recently. Moreover, the medical ess demonstrates week by week the growing terest and understanding of the practitioner in oblems of social organization. The biologist is rtainly not far behind his colleagues in developing ese new lines of investigation; the work at the ockham Centre has aroused the greatest interest, d research into problems of nutrition, housing, anufacturing processes, and so forth, is beginning achieve most important results.

It is therefore most disappointing to find in the ok under review no realization whatever of the ealth of new knowledge that is now being made ailable in this way. No attempt is made to develop the notion of 'human ecology' in its true sense which was first established on a biological foundation in the popular works of H. G. Wells. Instead, we find served up once again the outworn ideas which were fashionable among discontented young men with a political bent ten or twenty years ago. Much is said on the esoteric subject of 'social credit': many regrets are expressed concerning the unfortunate effects of the growth of the sovereign State; and the "true and secret source" of the "secret power which now dominates society" is found to lie "firstly and for all time in 'avidya', or unreality". The book ends in the lofty strata of the Hindu religion.

The present book is evidence of the fact that only a beginning has been made with the laying of the foundations of the science of man. It is nevertheless to be hoped that those trained in the biological sciences will be able to demonstrate that a more objective approach to the problems of social organisation is possible.

T. S. SIMEY

DEVELOPMENT OF ROMAN CONSTRUCTION

Ancient Roman Construction in Italy from the Prehistoric Period to Augustus

By Marion Elizabeth Blake. (Publication 570.) Pp. xxii+421+57 plates. (Washington, D.C.: Carnegie Institution, 1947.) 9 dollars.

THIS chronological study of the methods and materials used in Roman building is based on notes and photographs left by the late Dr. Esther Van Deman, who had been collecting evidence for many years for a work of this character. Originally it was intended to include all masonry in Rome and the vicinity from the earliest times to the fourth century A.D. or later; but as it was impossible, owing to the War, to complete the necessary field work in Italy, the author decided to terminate her work with the reign of Augustus, while broadening her field to include sites from all over Italy, as a background to developments in Rome. After a preliminary introduction defining the scope and character of the monograph, there follows a chapter on the materials available for building and decoration, namely, stone, clay, metals and wood. A brief geological survey precedes the description of the various types of stone, the sources from which they may have been obtained, and the chronological significance of the choice of material. Timber construction was employed for a variety of purposes; but its use was limited by the scarcity of suitable trees near Rome, and private houses especially were largely built of sun-dried brick.

The next four chapters are concerned with the various ways of building in stone, and they include accounts of the construction of roads, tombs, villas, theatres and temples in Italy during the whole of the period under review, as well as a discussion of the development of city walls from the cyclopean and other early forms. One chapter is devoted to squared-stone construction in Rome and its neighbourhood, and another to the building of arches and vaults in cut-stone work, and their use in such structures as city gates, commemorative arches, bridges, aqueducts and arcades. The fourth of these chapters deals with those methods of providing the stone facing for walls with a concrete core known as *opus incertum* and *opus reticulatum*, together with the intermediate stage of *opus quasi-reticulatum*. A short chapter on the origin and use of sun-dried and semi-baked bricks then leads to a more detailed description of kiln-baked brick and tile construction, including a useful account of the processes of manufacture and of brick-laying. Finally, we come to the consideration of those features for which the Roman builder is especially famous, mortar and concrete. Such traces of early mortars as survive are very friable, and it was only when the value of the volcanic product called pozzolana was realized that the renowned hydraulic mortars of great strength could be made. The colour and texture of both the non-hydraulic and hydraulic varieties differ with the proportions of the materials used for them, and on this account mortar is now seen to be of great value to chronology. The study of its changing colour and consistency has already helped to establish the dating of several Roman sites in Britain; and in Italy the similarities of such features may show the roughly contemporaneous development of building construction over a wide area. The history of concrete is closely bound up with that of mortar.

Throughout the whole book two features particularly attract the attention: first, the important part played by local resources in the development of building methods, a feature which became one of the characteristic signs of Roman influence throughout the Empire; and secondly, the summaries of the technical considerations involved in building, which are to be found in most of the chapters. These provide information which it is difficult for the student of ancient architecture to obtain without detailed study, and so are especially valuable. In her preface the author states that many things have been included in an attempt to ease the burden of future scholars, and in this connexion mention should be made of the very comprehensive indexes provided. Perhaps when her work on ancient mosaics is completed, she will give us a further study of Roman construction, continuing its history to the date originally designed by Dr. Van Deman.

JOAN LIVERSIDGE

VETERINARY PROTOZOOLOGY

Veterinary Protozoology

By U. F. Richardson. Pp. viii+240. (Edinburgh and London: Oliver and Boyd, 1948.) 10*s*. net.

THE number of books devoted entirely to the Protozoa is, in comparison with the number of books about other kinds of animals, unfortunately small. A new book about these beautiful, fascinating and biologically important organisms is therefore an interesting—and to some biologists an exciting—event. If the new book is, like the one which Mr. Richardson has written, restricted to the relatively few species of Protozoa which cause diseases of domesticated animals, this fact does not lessen the importance of its contents. For these species can kill many farm animals or can profoundly affect their health, and thus can effectively menace the food supplies of the world. Some of them can, moreover, cause serious diseases of man, while others are closely related to species which are among man's most powerful protozoal enemies. There are, therefore, plenty of economic reasons why the Protozoa parasitic in domesticated animals should be studied, and, for the same reasons, any book which helps us to contr them is an important one. Mr. Richardson's boo has, also, another claim to importance. Until h wrote it, there was no English book entirely devote to this subject, so that he has filled an importan gap in English biological literature.

The book under notice is not a large one, and it not, perhaps, as ambitious as it might have been yet it gives, in a small space, a surprising amount selected information. One of its most attracti characteristics is its author's simple and conci style, which enables him to convey to the read clearly and briefly an epitome of existing knowledg No doubt Mr. Richardson's experience of research c some of the species discussed and of the teaching veterinary protozoology have helped him to do thi His style is matched by the line drawings which h has wisely chosen to illustrate the book. These a well done; all the illustrations take this form, excep the coloured frontispiece, which is no doubt intende to show what various Protozoa look like in staine preparations, and the two photographs, one of th cæca of a chicken infected with *Eimeria tenella* an the other of the liver of a turkey afflicted wit 'blackhead' disease.

Addressed primarily to veterinary students and t workers in the tropics, where the diseases caused b Protozoa present some of the most serious problen encountered by the veterinarian, the book begi with a brief general account of the Protozoa, an then deals with the Sporozoa, Mastigophora, Amœb and Ciliates which cause the diseases discussed; an also with such organisms as *Globidium*, *Encephalit zoon*, *Rickettsia* and others, the classification of whic is doubtful. The characteristics and biology of eac species, or group of species, are dealt with, and th description of each species is immediately followe by a discussion of the methods of examining th tissues attacked, the lesions caused, the diagnosis the disease, the drugs used against each species an any immunity that the host may develop. The read thus gets a concise outline of each disease and i control in relation to the biology of the species whic causes it. The information given about the dru used for treatment of each disease will be especiall welcomed by some readers who are unable to re the journals in which this kind of information published, and they will also be interested in th chapter on chemotherapy at the end of the boo Another chapter discusses the techniques used f laboratory studies of these particular Protozo Valuable also are the short lists of references important literature given at the end of each chapte

The difficulties confronting anyone who attemp to write a book of this kind are considerable. Shorta of paper and production costs no doubt preclude, these times, the publication of a larger work, a certainly they limit the number and kind illustrations used. It has long been difficult, if n impossible, for any one man to keep himself ful informed about all the work that is being done the whole range of the parasitic Protozoa. Much the literature is scattered in journals in vario languages, many of which are not readily accessib and work on the treatment and control of protozo diseases is frequently inconclusive, so that opini about its value may be conflicting. Advances a moreover, being made continually, so that a man script may, through no fault of its author, be out date in places by the time it is printed. No read therefore, can expect, in a book on this subject, fin dgments on many of the problems discussed. He ill find in the present book, however, a great deal at will interest and inform him, and a great deal lso that will suggest to him lines of fruitful research. eachers will find in it the essentials of a subject the nportance and fascination of which are not often alized outside the veterinary schools.

Mr. Richardson is to be congratulated; and his ublishers have earned our gratitude for producing, t a moderate price, this attractive, easily handled nd well-printed book. G. LAPAGE

GARDEN, SMALLHOLDING AND FARM

mallholdings for Pleasure and Profit

uarter-acre Part-time Holding to Smallholding and arm. By W. V. Ball. Pp. 124. (Worcester: Little- ury and Co., Ltd., n.d.) 10*s.* 6*d.* net.

our Smallholding

dited by Alan Thompson. (Penguin Handbook H.13.) Pp. 192+8 plates. (Harmondsworth: enguin Books, Ltd., 1947.) 1*s.*

nallholder Broadcasts

ol. 3. From the Series of Broadcast Talks "Backs the Land". Pp. 95+8 plates. (Worcester: Little- ury and Co., Ltd., n.d.) 10*s.* 6*d.* net.

lowers, Shrubs and Fruit for the Small Garden

y G. A. Carter. Pp. 86+12 plates. (Worcester: ittlebury and Co., Ltd., n.d.) 9*s.* 6*d.* net.

'T may be claimed for the present post-war period that it has a substantial fund of good counsel vailable for newcomers to the land. Three of the oks under review aim at providing trustworthy lvice to smallholders, actual and potential, and in is they succeed.

The author of "Smallholdings for Pleasure and ofit" was an ex-Serviceman in 1921 who decided obtain a living from the land. His experiences of nall-scale farming, following a course of instruction the Hertfordshire Institute of Agriculture, are set it clearly in his book, and he presents the reader ith facts and figures of a highly enlightening aracter. Holdings ranging from a quarter of an re to those of 50-acre size are discussed, and oservations made on the capital required to run em. Advice is tendered on how to obtain a small- lding and on whether to purchase or to lease. The and Settlement Association Schemes are described, are land settlement schemes in several countries her than England. Illustrations, mostly of mech- ical aids for the small farmer, add to the value of publication certainly well worth perusal by the ospective smallholder.

"Your Smallholding" ably maintains the high andard established by Penguin Handbooks. In is volume emphasis is placed upon the part-time lding, the demand for which is likely to increase w that working hours are being shortened. Chapters aling with the keeping of cows, pigs, goats and bees e included, and rabbit-keeping is not forgotten. ace allotted to food crops is very limited and is voted mainly to fruit-growing. The unwarranted as against the use of mineral fertilizers, encountered the final chapter, is perhaps forgivable in view of e many words of wisdom to be found elsewhere. is handbook, enhanced as it is by several clear photographs, is wonderful value for the small sum which it costs.

In Smallholder Broadcasts, Vol. 3, much material of enduring interest has been put on permanent record and in handy form. Eight chapters are given to various aspects of poultry-keeping; six to bee-keeping; three to glasshouse crops; and pigs and waterfowl have a chapter apiece. The contributions, by thoroughly competent men, together make a particularly useful book which should be in the possession of every smallholder interested chiefly in livestock management.

"Flowers, Shrubs and Fruit for the Small Garden" is concerned with the garden having an area of between 500 and 800 square yards, that is, one which can be looked after by its owner without outside assistance. The author has made and owned several such gardens and now offers plenty of excellent advice to others. A few of his statements, however, ought not to pass unchallenged. The cultural directions are somewhat sketchy, the pruning of gooseberries, for example, being dismissed in one sentence. It were well to attend to leaky washers before rather than after spraying as advised. The illustrations are not as clear as they might be.

None of these books is provided with an index.

EPICURUS UP TO DATE

Matérialisme progressiste

Par Dr. Charles Mayer. Pp. 177. (Paris: Société française de Presse, 1948.) 150 francs

THIS is a clear and straightforward exposition of a type of philosophy more usually called positivism; for matter is taken to be that which the physical sciences study. It is a relief to find that 'progress' in the title means more knowledge, not bigger and better gadgets, and that the author acknowledges his kinship with the ancient Epicureans. There are differences, however. Epicurus, as expounded by Lucretius, was not interested in science except as a dogmatic stick to beat traditional religion with, whereas Dr. Mayer is interested, and on the purely scientific side writes very well. On the other hand, Epicurus' ethical doctrine was well thought out and based on a real understanding of human nature and the human situation of his day.

Dr. Mayer is content to reproduce the teaching of nineteenth-century utilitarianism and liberalism, modifying its individualism by insisting that welfare is social welfare; but does not examine its foundations or its applicability to the present world situation. In general, he is singularly unaware of philosophical problems. In the preface he sets out his fundamental assumptions: (1) there is nothing supernatural; (2) there are no transcendental truths; (3) the universe is not the product of thought, and its evolution is not predestined; (4) there are no final causes; (5) no facts but material ones; (6) thought itself is a spark (*étincelle*) derived from matter; (7) the mind cannot conceive of itself without matter. Of these, (7) might pass as empirical or 'scientific'; all the rest are transcendental truths (or falsehoods). Thus (2), unless carefully hedged about, is self-contradictory, and even so, unplausible in face of the others. The philosophy of Santayana could have shown Dr. Mayer where his assumptions lead if systematically worked out and how much room is then left for progress of any sort. A. D. RITCHIE

Active Psychology and the Welfare and Progress of Man

Notes on the Establishment of a Non-Medical Practical Psychology. By G. E. Witt. Pp. iii+88. (London: H. K. Lewis and Co., Ltd., 1947.) 7*s.* 6*d.*

THE late Dr. G. E. Witt was a pupil of Kraepelin and Bonhoeffer, and it might have been expected that he would produce an authoritative book. Unfortunately, this present one does not fulfil its grandiose title, and is disappointing. A foreword states that it is "A collection of thoroughly worked through and paragraphised notes. These notes or paragraphs have kept their independency. The sequence is fortuitous." This places a strain on the reader. The foreword admits "This mode of presentation has its advantages and its disadvantages. The disadvantages can be reduced by an index." Perhaps an index will be a part of the second volume; none is provided in the present one.

Dr. Witt's views show that he felt that psychiatry should be expanded into 'active psychology', which is defined in paragraph 2 as "An applied psychology. Resulting from certain perceptions it is a practical method of working psychologically upon the human mind." But unfortunately it continues by stating: "The method, and its foundation, will be explicitly dealt with in another volume". It seems that Dr. Witt believed that by emancipating psychiatry from general medicine and by widespread training in 'active psychology' a revolution would occur in social life as well as treatment.

The style of this book is repetitive, the exposition disjointed and difficult to follow, and much of the matter is dependent on a further volume. The printing and paper are good, and the book is paper bound.

Using and Managing Soils

By Prof. A. F. Gustafson. (McGraw-Hill Rural Activities Series.) Pp. xii+420. (New York and London: McGraw-Hill Book Co., Inc., 1948.) 17*s.*

THE object of this book is to provide the intelligent American farmer, smallholder or gardener with a short account of the scientific principles of soil management. The author, who has written several well-known books, is professor of soil technology at Cornell University, and among the topics he discusses the following are most relevant to British conditions: cultivation, drainage, maintenance of fertility, the best ways of using farmyard manure and green manures, and the proper use of fertilizers and crop rotations. He gives many examples of management; but, for obvious reasons, these mainly refer to the agriculture of the north-eastern and middle-western United States. Thus the book is unsuitable for the corresponding practical man or student in Britain. On the other hand, lecturers in crop husbandry at farm institutes and agricultural colleges in Britain will easily be able to pick out from the discussion the principles applicable to British agriculture.

The great difficulty in writing any book such as this is to combine simplicity with accuracy and conciseness with adequacy of presentation. There are a number of places where the reviewer is not in full agreement either with the adequacy or accuracy of the science, or with what has been omitted or included. But his main criticism is that at several places the general principles are not brought out as clearly as they should be, so that no indication is there given of the generality of the results stated, the reasons for them.

The book is very well produced, is copious illustrated and contains many tables of experiment results.

E. W. RUSSELL

Discharge Lamps for Photography and Projectio

By H. K. Bourne. Pp. xv+424. (London: Chapma and Hall, Ltd., 1948.) 36*s.* net.

A BOOK written by a research worker, whic deals with the subject in which he has specializ for a number of years, is always worthy of attentio and Mr. H. K. Bourne's "Discharge Lamps" is exception to this general rule. The title is perha somewhat misleading, as there is a not inconsiderab section dealing with incandescent filament lamps an carbon arcs, as well as a section later in the boo dealing with photographic flash lamps of the aluminium foil or wire type.

There are many people, whether belonging to th class of student or lecturer or potential user, wh have not been in a position to follow the rap developments of the last two decades in the fie of light sources, to whom this book will prov valuable for reference purposes. Account h obviously been taken of most of the important pape which have been published on this subject as well of the patent literature.

Mr. Bourne's book contains much data an information published for the first time, and it ca be strongly recommended as an authoritative wo covering a large section of the field of special-purpo illuminants. It gives in conveniently summariz form data on the electrical and luminous properti of most types of electric discharge lamp at prese available. The sections dealing with applications w no doubt stimulate further interest in these relative new light sources.

J. N. ALDINGTON

The Hunting Wasp

By John Crompton. Pp. 255. (London and Glasgow Wm. Collins, Sons and Co., Ltd., 1948.) 10*s.* 6*d.* ne

THIS book may be described as a popularizati anew of the writings of Fabre and the Peckha on the habits of the solitary wasps, enlivened by number of personal anecdotes not always abo insects, the whole written in a vivid and racy sty which makes for easy reading. The author's mann may be sufficiently illustrated by his description the wasps' nest in winter. "The long low-ceiling halls echo vacantly. The cradles in their thousan lie empty. Vermin creep in: the mouse, the earwi and the beetle keep the courts where Vespa glori and drank deep".

The subject is presented in terms of an unblushi anthropomorphism; the intelligence of insects taken for granted, but there is criticism and a se reliant philosophy of the robust common-sen variety to be expected from a man who has knock about the world.

A number of mis-spellings and small errors of fa do not detract seriously from a very readable boo But in justice to the entomologists of the Ministry Agriculture, who have been conducting a well-plann and highly successful campaign against the Colora potato beetle, it may be pointed out that it was n the British Government "frightened by the threaten invasion" which offered a reward of £10 for eve Colorado beetle; that ill-conceived measure can from a newspaper office.

V. B. WIGGLESWORTH

COLOURING MATTERS OF THE APHIDIDÆ

By H. DUEWELL, J. P. E. HUMAN,
R. A. W. JOHNSON, DR. S. F. MACDONALD
AND
PROF. A. R. TODD, F.R.S.
University Chemical Laboratory, Cambridge

THREE colouring matters (cochineal, kermes, lac-dye) derived from insects belonging to the occidæ have long been of commercial importance nd have been the subject of extensive chemical vestigation. Although many of the related Aphididæ re highly pigmented and are of very common ccurrence, chemical investigation of their pigments as been very scanty. No doubt one reason for this ate of affairs has been the comparative difficulty f collecting adequate supplies of insect material; ut the small amount of information available sugsts that some aphids at least contain colouring atters possessing unusual properties.

An early paper by Sorby[1,2] described an examinaon of the colouring matters of the "red Aphides" und "in downy patches on the bark of the apple ee". Although not expressly stated by Sorby, this sect was presumably the common woolly aphis *Eriosoma lanigerum*, Hausmann). From these and ther aphids he obtained in solution a remarkable ries of inter-related pigments, and although these ere not isolated they were identified by their chareteristic absorption spectra, details of which were corded. Extraction of freshly killed insects with ater gave a solution of the red "aphideine", which as not isolated; but on standing in air it rapidly ssed into the yellow water-insoluble "aphidilutne", which in turn was transformed into an orange gment, "aphidiluteoleine", on standing for longer riods. On still further exposure to the air, a red louring matter was formed which was named aphidirhodeine" and which appeared to form relavely stable solutions. If the crushed insects were t extracted immediately, no aphideine was obtained it only mixtures of the other derived pigments, the lative proportion of which varied according to the me of standing. Details were given of the colour anges of the various colouring matters in acid and kaline media, and it was concluded that, although e pigments were in some respects analogous to emoglobin, the "physical and optical properties ffered completely from those of the colouring atters of the cochineal insects of commerce". Many ars later, Blount[3], unaware of the work of Sorby, lated from the woolly aphis the crystalline orange-d lanigerin, $C_{17}H_{14}O_5$; but the constitution of the gment was not closely studied. It was recorded, wever, that lanigerin formed a deep red solution concentrated sulphuric acid and a crimson solution sodium hydroxide.

Blount[3] also reported the isolation of a red pigment, robinin, from white pine chermes, *Adelges* (*Pineus*) *obi* (Börner). Strobinin gave analytical values rresponding to a formula, $C_{30}H_{24}O_8$, but was not rther examined because of shortage of material, . *strobi* being of only limited occurrence in England. robinin formed a green, sparingly soluble, sodium lt and showed a remarkable colour reaction with acetic anhydride containing a drop of sulphuric acid, the initially reddish solution changing rapidly through green to a pure blue, with simultaneous appearance of an intense red fluorescence. Our interest in this subject was intensified when, a few years ago, one of us examined in a preliminary fashion a small number of black aphids (*Aphis fabœ*), and found that crude extracts of the dried insects showed certain colour reactions similar to those described for strobinin by Blount[3].

During the summer of 1947, *A. fabœ* was prevalent in the Cambridge area on its usual host, the broad bean (*Vicia faba*), and when it was confirmed that it yielded a red pigment giving the characteristic acetic anhydride – sulphuric acid reaction of strobinin, a systematic investigation of the colouring matters of the insect was undertaken. At that time we, too, were unaware of Sorby's paper. The results so far obtained in our investigations on this and other aphids appear to be of sufficient interest to warrant their publication at this stage.

In the course of preliminary studies on the extraction of fat-soluble pigments from *A. fabœ*, it quickly became apparent that the red colouring matter with reactions similar to strobinin is not actually present in the living insect but arises from a yellow precursor, after death of the insect, the change being greatly accelerated by heat or by traces of acid or alkali. When this change was followed spectroscopically by extracting the insects with 80 per cent aqueous acetone and then partitioning the pigments into light petroleum, the yellow precursor proved to be a mixture of a yellow and an orange colouring matter, both of which underwent conversion to the red pigment either spontaneously or, more rapidly, under the conditions indicated above. Under mild conditions the 'primary' yellow pigment could be converted into the 'secondary' orange pigment, and all observations indicated that the primary yellow could only be converted to the red with the intermediate formation of the secondary orange pigment.

In order to obtain these pigments, the fresh insects were extracted with 80 per cent acetone and the pigments taken into light petroleum from the acetone. The petroleum extract was then rapidly concentrated at room temperature until a granular product separated which gave the primary yellow and the secondary orange pigments on fractional crystallization from carbon tetrachloride. These substances, when dissolved in ethyl acetate and a little formic acid added, gave the crystalline red pigment.

Although, as ordinarily obtained from fresh insects, the crude fat-soluble pigment was a mixture of all three colouring matters in varying proportions, it seemed probable that all were artefacts, for the extraction with 80 per cent acetone was considerably facilitated when the crushed insects were first allowed to stand in contact with air for periods of up to one hour. Further investigation showed that if living insects were treated with water at 70°, no pigments could then be extracted with organic solvents; but a crystalline yellow water-soluble precursor of the above pigments could be isolated. Thus, after the preliminary treatment with hot water the insects were extracted with 60 per cent methanol. Fat was removed by extraction with light petroleum and the methanol removed *in vacuo* from the aqueous layer. Adsorption on active charcoal followed by elution with 75 per cent acetone and evaporation of the eluate gave the pale yellow water-soluble colouring matter crystallizing in flat needles. It formed a port-wine coloured solution in alkali, and addition of crushed aphids to its aqueous solutions caused rapid conversion to the 'primary' yellow fat-soluble pigment, presumably as the result of enzymic action. Other water-soluble pigments, green and brown respectively, apparently unrelated to this series, have also been found in extracts of *A. fabæ*.

Our investigations have been further extended to include the following species of coloured Aphididæ: *Tuberolachmus salignus* (Gmelin) from willow trees (*Salix alba*), *Aphis sambuci* L. from elders (*Sambucus nigra*, L.), *A. rumicis* L. from docks (*Rumex obtusifolius*, L.), *A. viburni* Scop. from *Viburnum* spp., *A. ilicis* Kalt. from *Ilex aquifolium* var. *crispifolium-variegatum*, *Sappaphis pyri* (Fonsc.) from cultivated pear trees (*Pyrus communis*), *S. plantaginea* (Pass.) from cultivated apple trees (*Malus pumila*), *S. cratægi* (Kalt.) from garden parsley, *Myzus cerasi* (F.) from wild cherry trees (*Prunus cerasus*, L.), *Dactynotus jaceæ* (L.) from the greater knapweed (*Centaurea scabiosa*, L.), *D. cirsii* (L.) from thistles (*Cirsium lanceolatum*, L.) and *Eriosoma lanigerum* (Hausmann) from cultivated apple trees. Fat-soluble colouring matters analogous to those isolated from *A. fabæ* have been obtained from *T. salignus*, *A. sambuci*, *A. rumicis*, *S. pyri*, *S. plantaginea*, *M. cerasi* and *E. lanigerum*, and their presence in *S. crataegi*, *A. viburni* and *A. ilicis*, of which only small amounts have as yet been available, has been demonstrated by spectroscopic examination of extracts. The pigments isolated from *D. jaceæ* and *D. cirsii* differed from the others in that the 'secondary orange' pigments were much redder in colour and that neither of the 'primary yellow' pigments were isolated. Further work on these species is in progress.

The nomenclature of these pigments presents a number of problems, partly because of the desirability of some generally applicable scheme, and partly because of the possibility that some of the substances isolated from different species may prove to be identical. For these reasons it is felt that such names as 'strobinin' and 'lanigerin' are not wholly satisfactory. It is proposed that the water-soluble pigment in the insect should be called a 'protoaphin', and that the primary yellow pigment derived from it by enzymic action, a 'xanthoaphin'. The secondary and tertiary pigments derived from the latter would be 'chrysoaphin' and 'erythroaphin'. It is further proposed that, for the present at least, the pigments from each species should be distinguished by adding to each of these stem names a two-letter suffix based on th name of the insect species. Thus the pigments fro *A. fabæ* are described as protoaphin-*fb*, xanthoaphi *fb*, chrysoaphin-*fb*, and erythroaphin-*fb*; those fro *T. salignus* take the suffix -*sl*, from *A. strobi* -*st*, *lanigerum* -*ln*, *A. sambuci* -*sm*, *A. rumicis* -*rm*, *plantaginea* -*pl*, *S. pyri* -*py*, *S. cratægi* -*cr*, *M. cera* -*ce*, *D. jaceæ* -*jc*, *D. cirsii* -*ci*, *A. viburni* -*vi* an *A. ilicis* -*il*.

Details of the pigments obtained from *A. fabæ* a given in the accompanying table.

The xanthoaphins, chrysoaphins and erythroaphi from all the species listed above have very simil and characteristic absorption spectra in the visib region, and examination with a hand spectrosco is a convenient method of identification. Melti points can seldom be used as criteria of purity in th series, and the similarity in absorption spectra leav open the possibility that some, although not all, the corresponding pigments isolated from sever species may be identical. Of the species mention above, *T. salignus* and *A. fabæ* have been the mo exhaustively studied. The former, which at tim causes heavy infestation on willow trees, is mc readily collected alive and undamaged than *A. fab* is usually less contaminated with parasites a foreign insects and has a relatively high content colouring matter (1·3 per cent). As in *A. fabæ*, t living insects contain a protoaphin occurring in t hæmolymph, and this pigment rapidly chang after the death of the insect to fat-soluble xanth aphin-*sl*, readily converted in turn to chrysoaphin and erythroaphin-*sl*. Although closely similar to t corresponding substance from *A. fabæ* in its cor position and its properties, erythroaphin-*sl* gives different X-ray powder photograph.

Our results confirm in every respect the findin of Sorby in showing that representatives of t remarkable class of pigments are found widely amo the Aphididæ. It is evident, too, that strobinin c responds to our erythroaphins, and indeed an X-r powder photograph of a specimen kindly suppli by Dr. Blount indicated that it is probably identi with the *T. salignus* pigment. From the record its colour reactions, Blount's lanigerin is alm certainly one of our chrysoaphins (chrysoaphin-*l* Chemical investigation of the structure and int relationships of all the colouring matters is bei undertaken in this Laboratory and the work is bei extended to include other insect species as th become available.

Pigments from *A. fabæ*

† Determined visually on a microspectroscope.

Most of the chemical work so far carried out has been done on the erythroaphins-*fb* and -*sl*, as these have been available in the largest quantity and hey are the most stable members of their respective series. They are tenaciously held on alumina or alcium hydroxide chromatograms, and although some purification can be effected on talc columns, hromatography has not been generally employed. Solutions of these pigments show an intense fluorscence which is red in daylight and orange in ultraviolet light. They have no definite melting point but decompose with considerable charring above 00°, and they cannot be sublimed even in a high vacuum. They are readily soluble in pyridine, much ess so in acetone, chloroform and carbon tetrachloride and very sparingly so in ethanol, ether and the other common organic solvents. Solutions in aqueous pyridine, sodium hydroxide and sodium carbonate are bright green and deposit green amorphous precipitates on standing. They contain neither nitrogen, halogens, sulphur nor methoxyl (Zeisel). Erythroaphin-*fb* contains acidic hydroxyls (0·84 per cent active hydrogen; Zerewitinoff) and several C—CH_3 groupings (12·4 per cent; Kuhn – Roth). Considerable difficulty has been encountered in obtaining consistent analytical values both for these substances and for the xantho- and chrysoaphins owing mainly to their tenacious retention of small amounts of solvent, but the results of a series of analyses suggest that the erythroaphins have an empirical formula $C_{15}H_{12}O_4$.

Low solubility in suitable solvents and tendency to decompose at higher temperatures have prevented accurate molecular weight determinations; the acyl derivatives, although more suitable for this purpose, still give variable results. In the case of erythroaphin-*fb*, X-ray analysis of the crystalline material indicates a molecular weight of either 260 or 519 ± 3 per cent according to whether the unit cell contains eight or our molecules. The higher value is in better accord with the results of cryoscopic determinations on the benzoyl derivative and would also be more in keeping with the intense fluorescence and extremely sharp absorption bands shown by the pigment, so that we have adopted provisionally a molecular formula $C_{30}H_{24}O_8$ for erythroaphin-*fb*.

Hydrogenation of the erythroaphins in presence of a platinum oxide catalyst or reduction with sodium hyposulphite yields orange fluorescent leuco-compounds which are rapidly re-oxidized in air, suggesting the presence of a quinonoid structure in these pigments. The exact nature of the nucleus as well as the nature of the changes involved in the series of conversions protoaphin → xanthoaphin → chrysoaphin → erythroaphin are still obscure.

It is of considerable interest that there is a very trong general resemblance between the properties of the erythroaphins (even to the difficulty of analysis and molecular weight determination) and those of hypericin, the photodynamic colouring matter of St. John's wort[4,5], which has been provisionally formulated as a polyhydroxy-*meso*naphthodianthrone deivative, and it seems not unlikely that they are related in structure. Using *Paramecium* as test organism, Prof. D. Keilin has shown that erythroaphin-*sl* is strongly photodynamic. It is noteworthy that Dhéré[6] has already remarked on the similarity between the ultra-violet and fluorescence spectra of hypericin, lanigerin (chrysoaphin-*ln*), strobinin (eryhroaphin-*st*) and the mould pigment oxypenicilliopsin[7].

Full details of the investigation here outlined will be published elsewhere. We record with pleasure our gratitude to Mr. H. L. G. Stroyan for his invaluable assistance in locating and identifying the various Aphididæ which we have examined, and to Dr. W. Cochran for the X-ray crystallographic examinations.

INSTRUMENTATION AND CONTROL IN INDUSTRY

SECTION A (Physics) of the British Association held a symposium on September 14 on "Instrumentation and Control, including Electronic Devices". The discussion was opened by Sir Ewart Smith, who spoke on "The Contribution of Instruments to Industrial Progress".

"The instrument field is already a vast one and it is extending rapidly as the result of advances in physical science on the one side, and the ever-growing demands of industry on the other. Industrial processes are becoming more complex in detail and the size of the unit is continually tending to increase; in addition, there is the demand for higher efficiency, for continuity in operation and for better control of finish and consistency, all of which call for a higher degree of instrumentation. Better instrumentation in turn leads to still wider possibilities of technical progress."

Sir Ewart summarized the main stages in the historical development of instrumentation, to indicate the lines future progress might be expected to follow, and stressed both the dependence of modern industry on instrumentation and the need for a new outlook with regard to it. When a large and complex industrial plant may depend entirely on instruments for its automatic control, it is clearly time to regard these instruments not as accessories but as an integral part of the plant. They are, in fact, the heart and brains around which the process should be designed. Industry is now recognizing this important fact, and is attempting to secure the full potential benefits of automatic control in this way.

Relation between Research and Industrial Application

Sir Ewart directed attention to the way in which an industrial instrument is frequently developed from a laboratory instrument which has been designed to meet a need in research, and stressed the important part played in the development of the instrument from one stage to another by the 'development' or 'design' engineer. He emphasized the vital need which had been pointed out at several previous meetings of other sections, and by Sir Henry Tizard in his presidential address to the Association, for ensuring that Great Britain possesses a sufficient number of properly trained applied scientists to take the knowledge made available by the research worker and to put it to effective use in industry.

The applied scientist has a very large part to play in revitalizing the national economy of Britain, for upon his ability must depend progress in applying the large amount of knowledge which has been discovered by the research worker. The applied scientist's function is to be the essential link combining together the potentialities of research, the requirements of the user and the possibilities of fabrication and construction in the industrial field. Sir Ewart defined 'development' as "the process of bringing knowledge derived from research to the state in which it can be applied directly to useful ends". The development engineer must therefore be an applied scientist in the true sense of the term, and it has been in the training of such men that Britain has not made the best use of its potentialities.

Sir Ewart recalled that at a previous meeting of the Association he had defined research as "the process of gaining knowledge in a systematic manner by the study of phenomena, or by the examination and correlation of existing data". Much attention has recently been directed to the importance of research work as defined by the first half of this definition; but Sir Ewart stressed very strongly that the time has now arrived when it is proper to emphasize the importance of work defined by the second half. As knowledge becomes more and more specialized, the need for co-ordination of the various specialized fields increases—for without it existing knowledge cannot be applied promptly to industrial problems. It is, therefore, necessary to give very serious thought to methods of correlation, indexing and dissemination of detailed knowledge in a form suitable for the applied scientist to use. At the same time, the student must be taught how to find such knowledge when it is required.

Sir Ewart said that in order to make effective progress, it is far more important that the applied scientist should have the right approach than that he should possess a vast fund of detailed knowledge. The universities and technical colleges should aim primarily at training men to understand basic principles, to be critical and to think for themselves. Educationists and industrialists alike should make it their duty to see that a proper proportion of the best brains coming forward should be trained in this manner to undertake the vitally important and supremely interesting work of development and design over the whole industrial field. If a sufficient number of applied scientists is assured, industrial progress will be accelerated and the fruits of research will be used to benefit the community much more promptly than is normally the case now.

Standardization of Technical Terms and Equipment

As a corollary to the need for correlation of information, so that it is easily accessible to the applied scientist, attention was directed to the equal need for standardization of units, definitions and general methods of presentation. It is in general agreed that such standardization would be extremely beneficial; but when attempts are made to obtain it, difficulties arise immediately. These difficulties are undoubtedly very real; but it is certainly worth while making individual sacrifices in order to overcome them.

Sir Ewart suggested that the whole subject of education of the applied scientist, and the correlation and indexing of information to make his work more efficient, is one worthy of discussion by the British Association, which provides a natural forum for the general consideration of such matters. This suggestion was warmly welcomed by the president o Section A, Sir Lawrence Bragg, who suggested tha a special session should be devoted to these matters at a future meeting of the Association.

From the standardization of units and nomenclature, it is a natural step to the standardization o material things. Sir Ewart advocated a very much greater degree of standardization of equipment and components in order to reduce production costs, and to assist interchangeability. It was made quite clea that it was not intended that this standardization should apply, for example, to complete instruments but only to those dimensions or components o instruments which are commonly used. Far from hampering progress in design, such a measure o standardization would accelerate progress—as ha been clearly demonstrated in other fields where standardization had been applied. Sir Ewart quoted the instance of the recent discussions between the United States, Canada and Great Britain on the standardization of screw threads. Here a major degree of tentative agreement has been reached, and it is hoped that all concerned will do whatever is possible to bring the discussions to a fruitful end. By putting off the problem to a future date the difficulties are only increased. They should be tackled now in a realistic and effective manner, instead of leaving them to increase in difficulty year by year.

In conclusion, Sir Ewart said that to obtain the most rapid progress in instrumentation, it is essentia to adopt a progressive and critical outlook; to ensure that a large number of properly trained applied scientists are available to industry; to obtain acceptance of common standards of measurement and nomenclature; to index available knowledge to make it easily accessible; to increase the measure o standardization of some types of equipment, and to make sure that industrial processes are designed to give full scope to the potentialities of automatic control.

Use of Electronic Instruments in Iron and Steel Making

The need for good presentation of basic principle and good design was again stressed by Mr. S. S. Carlisle in his paper on "The Use of Electroni Instruments in Iron and Steel Making". The iro and steel-making industry is at present carrying through an extensive programme of modernization and development, and is thus finding wide use fo the latest techniques of industrial measurement an control. There is, however, an understandable tendency to adopt techniques which are firml established as reliable and suitable for continuous operation in the particularly rigorous conditions encountered. Those responsible for operating stee plant are keenly interested in electronic instruments but sufficient confidence has not yet been inspired i electronics to create a great demand for them.

Mr. Carlisle believes there are three main reasons for this. In the first place, very exaggerated claim have been made for electronics as a solution to ever problem. Secondly, the impression has not bee dispelled that electronic equipment is fragile an inevitably extremely complicated. Thirdly, insuffcient attention has been given, in general, to the design of electronic equipment to meet the requirements of the heavy engineering industry—which a robustness, continuous operation and immunity t large temperature variations, to dust, to fumes and to vibration.

A great wealth of information has been made available by research work; but design technique, it was suggested, has not progressed sufficiently rapidly to use this information to the best advantage for industry. The development of the operating principles and of the techniques of using the thermionic valve has progressed at such a pace during the war years that the establishment of sound design technique applicable to industrial use has been rather left behind. This may result from the ease with which thermionic valves can be used to construct measuring devices without the necessity of giving a great deal of attention to good engineering design. There has also been a tendency to instal such instruments on the plant before they have been sufficiently tested and developed.

Mr. Carlisle said that the greatest help to a proper application and use of electronics in industry would be rendered by the clear presentation of the basic principles used. The number of actual electronic components necessary to build up equipment for instrument needs is small, and a thorough understanding of the characteristics and limitations of these components and the circuits into which they are built would immediately remove much of the suspicion with which electronic equipment is regarded by those who run industrial plants. Mr. Carlisle proceeded to illustrate his general points by reference to particular types of installations, and then described in some detail the problems of temperature measurement in the steel industry and the methods used to overcome them. Unfortunately, there was insufficient time for Mr. Carlisle to give descriptions of several instruments which had been developed specially for the steel industry; but these, no doubt, will be published in the literature in due course.

In summing up his remarks, Mr. Carlisle suggested that electronic instruments will ultimately find preference over the established systems because of their greater flexibility, in design and application, their simplicity and their suitability for production in large numbers at low cost. There is clearly a strong argument for their use when so large a proportion of the measurements required are, or can be, made by primary measuring elements giving an electrical output. It was emphasized once again that the information and the components are available; it only remains to provide good application technique and sound design for the arduous operating conditions experienced in the heavy engineering industries.

Servo Mechanisms

No better example of what can be done in a specialized field to implement Sir Ewart Smith's plea for better training, more correlation of specialized knowledge and more standardization of terminology, etc., could be found than in the work described by Prof. K. A. Hayes in his paper on servo mechanisms.

The rapid development required for Service needs during the War led to production of a new fundamental theory and a new approach to design. It also led to a new technique for testing—which in itself is of very considerable scientific interest. The complexity of the equipment called for a new type of technician capable of dealing with the intricate circuits and mechanisms evolved; for example, in the No. 10 Predictor there are several servo mechanisms and numerous three-stage amplifiers connected in a very complicated manner. To maintain such equipment in the field, it was necessary to train a large number of men who could think for themselves and use their initiative in carrying out repairs in the field. The ability to reason was called for in a high degree.

It fell to the lot of the Military College of Science to take a large part in working out a suitable training scheme and putting it into operation. The methods of teaching adopted should be of great interest to those in industry who have similar—although perhaps less complicated—problems to deal with. Although this training scheme was worked out for the maintenance man as opposed to the design engineer, it was initiated with the same intention as lies behind Sir Ewart Smith's suggestions. It was designed to inculcate ability to think rather than to amass a large amount of detailed knowledge—which in this instance would have proved useless in the field.

Prof. Hayes outlined the growth of servo mechanism technique, which had achieved rapid advances in the period 1925–38, and even more rapid advances since, during the Second World War. It was recognized by the Services at an early stage that the degree of accuracy required for gunnery, navigation, etc., could only be achieved by the use of automatic computing and controlling devices. Establishment of the underlying fundamental principles of the theory of position control followed quickly, and upon these principles the war-time success in the application of servo mechanisms was built up.

It is interesting to note the high order of performance demanded of the equipment required. For example, even a comparatively light gun weighs a matter of several tons, has a moment of inertia of order 10^6 lb./ft.^{2} units, and yet may be required to move at rates up to 30°/sec. with an acceleration of as much as 10°/sec./sec. It must be trained to coincide continuously with the directing device with an accuracy of a few minutes of arc. The precision of the servo mechanisms was such that the limit to the accuracy of the whole system in this kind of application was normally set by that of the gears and bearings, and the rigidity of the frame and mounting, etc., of the heavy equipment to be moved.

A simplified example of position control was shown to illustrate the fundamental techniques employed. The importance of 'monitoring feed back' was stressed, and the difficulties introduced by the 'stiffness', natural period of oscillation, and lags in the system, were indicated. Time did not permit any detailed discussion of the correcting controls necessary to overcome them.

The amount of work proceeding in various Service establishments during the War on servo mechanisms was such that in order to spread the available information among all concerned and to stimulate discussion among them, the Ministry of Supply Servo Panel was suggested by Dr. A. K. Soloman and was formed under the chairmanship of Sir John Cockcroft, who was later succeeded by Prof. D. R. Hartree. The Servo Panel held regular meetings at which papers were read and discussed in the manner of a learned society, and special panels were set up to deal with particular aspects of the problem.

It is interesting to note how the Servo Panel performed many of the functions of correlation and codification of information, standardization of nomenclature and terminology, which Sir Ewart Smith had already stressed as being so vital to the applied scientist in the whole industrial field. Prof. Hayes reminded the meeting that the library of the Servo Panel, which contains one of the most comprehensive ranges of books in existence on servo technique, is still available in the Ministry of Supply.

In conclusion, Prof. Hayes, commenting on the general nature of servo mechanism theory, said that the testing techniques evolved are being used to examine the nervous and muscular response of human beings, and that Prof. Tustin has suggested that the theory will predict the oscillations of an economic system.

The two papers which followed were more specialized. Dr. Uttley's paper directed attention to the great utility of servo mechanisms in the field of automatic spectrophotometry and, therefore, followed on very fittingly from the general discourse given by Prof. Hayes.

Dr. D. Gabor's paper, "Microscopy by Wave-Front Reconstruction" (see also *Nature*, **161**, May 15, 1948), was not related directly with those which had preceded it. The new method of obtaining increased resolving power is expected to be of great importance in electron microscopy; and calculations show that it should be possible to obtain a resolving power of one Angstrom unit—which would make it possible to resolve the atomic structure of molecules which are not suitable for the usual methods of structure analysis. An interesting demonstration of the method, using an optical model, was given later in the day.

A. J. YOUNG

OBITUARIES

Prof. Johan Hjort, For.Mem.R.S.

THE scientific work of Prof. Johan Hjort, who died on October 7, shows three overlapping phases. As a young man, after his university training at Oslo and Munich, he spent some time at the Zoological Station in Naples (where he met MacBride and Boveri) investigating a problem of pure zoology, the development of the bud in the ascidian *Botryllus*, with special reference to the germ-layer theory, then in full vogue. His paper, published in 1896 (*Zool. Res. Norwegian North Atlantic Expedition*), is still regarded as outstanding by modern experts on the group. Until 1900 he was lecturer in zoology at the University of Oslo and seemed headed for an academic career. But even in this first phase his interests turned to the sea and its practical problems, for it was in 1897 that he made his first discoveries about the Norwegian prawn and its commercial possibilities.

His great period as a marine biologist and fishery expert began in 1900, when he was appointed director of fisheries in Norway, a post he held until 1916. He had at his disposal an excellent research vessel, the *Michael Sars*, and made extensive cruises in her, not only in Norwegian waters but also so far afield as Spitsbergen and Jan Mayen. Hjort was always happy in a ship. His investigations were not only scientific but also practical, for he had always the welfare of the fishermen at heart. By charting the distribution of the pelagic eggs of the cod, he was able to discover lucrative banks that had never been fished before, the high concentration of eggs indicating the presence of great spawning shoals; the results of this early work were published in "Fiskeri og Hvalfangst i det nordlige Norge" (Bergen, 1902). He advised the International Council to undertake a co-operative study of the spawning areas of the Gadoid fishes, and was largely responsible for organising the research, which resulted in the publication in 1909 of the classical report of "Committee A" (*Rapp. Proc. Verb. Inter. Council*, **10**).

Hjort's greatest achievement in this brilliant period was his elucidation of the problem of good and bad years in the herring and cod fisheries of Norway. With the help of able assistants—Dahl, Damas, Lea and Sund—Hjort made a vigorous attack upon the practical problem of why these fisheries showed such big variations from year to year. It happened, fortunately, that at the time when Hjort's work started, the technique of age-determination in fish by means of scales and otoliths was just being worked out. Under Hjort's direction this method was applied with great success to the study of the herring, particularly by Einar Lea, and it soon became established that the main cause of the fluctuations in the great spring herring fishery was the success or failure of the individual broods or year-classes composing the stock. Thus it was found that the 1904 year-class was remarkably abundant, and predominated in the catches for many years, while succeeding year-classes were very poor. Similar methods applied to the Norwegian cod, supplemented by extensive measurements, demonstrated the existence of specially prolific brood-years, as, for example, those of 1904 and 1912, while other years contributed little to the stock. Preliminary results for the herring were published by Hjort and Lea in 1911 (*Pub. de Circ.*, No. 61) and a full study of the question by Hjort in 1914, in an extensive paper on "Fluctuations in the Great Fisheries of Northern Europe" (*Rapp. Proc. Verb.*, **20**). In 1914, at the request of the Canadian Government, he investigated on the spot the herring of the Gulf of St. Lawrence and adjacent waters, and found that their age-composition was similar to that of the Norwegian herring.

The study of fluctuations and their possible causes, initiated by Hjort, became a principal theme in all fishery and marine biological research for many years, and at Hjort's instigation it was frequently discussed at the International Council, particularly in the special scientific meetings which he introduced in 1926 (see, for example, *Rapp. Proc. Verb.*, **65** and **68**; 1930). Hjort returned again and again to this problem, right up to the last.

Hjort was above all a great biologist, with a profound interest in, and understanding of, the relations between the organism and its environment. This is made particularly clear in the chapter on general biology which he contributed to that admirable book "The Depths of the Ocean" (1912), familiarly known as "Murray and Hjort". This book was the outcome of a four and a half months scientific expedition in the North Atlantic in 1910 in the *Michael Sars*, chartered for the purpose by the famous oceanographer Sir John Murray. The cruise gave Hjort a renewed interest in the general problems of marine ecology.

After his retirement from the post of director of fisheries in Norway, Hjort became a professor at the University of Oslo, and the third phase of his scientific odyssey began. Though he still retained his keen interest in fishery problems and continued to be a dominant figure in the International Council his mind turned more towards general scientific and social questions. He gave much time to private study, including a period spent at Cambridge.

In 1921 he published a small book on general scientific method, "The Unity of Science", and in 1931 a larger volume called "The Emperor's New

Clothes", in which he attempted to show that modern physical theories were nothing but fairy tales, inconsistent with experience and reason. Hjort was not at his best in abstract thinking, and his incursions into philosophy and scientific method were not, to my mind, altogether happy. In both books, however, as also in his later publication, "The Human Value of Biology" (Cambridge, Mass., 1938), the sections in which he expresses his ecological attitude to the problems of life are excellent.

But Hjort was much too practical a man to devote himself to purely philosophical studies, and as professor at Oslo he did not neglect research, much of it concerned with practical issues. He took up with vigour population studies in organisms so diverse as yeasts and whales, and with his fellow-workers published many important papers in the series of *Hvalrådets Skrifter* (see particularly No. 7; Oslo, 1933). The sigmoid curve fascinated him. His views on population growth and the social problems involved are set out in his Huxley Lecture of 1934 entitled "The Restrictive Law of Population". Arising out of his population studies he worked out, with G. Jahn and P. Ottestad, the theory of the 'optimum catch', of great importance in connexion with the signs of over-fishing which were becoming apparent in the intensive whale fishery (largely Norwegian) in the Antarctic. The study of the whale population in these waters engrossed him in later years, and his studies were not limited to statistics and reports; he went out to the Antarctic to see for himself what the conditions of the fishery really were —an action typical of the man. He played a considerable part in the international negotiations which led to some measure of control being imposed on the fishery, and kept the International Council in touch with whaling problems.

In 1936 Hjort was invited to attend the celebration of the three hundredth anniversary of Harvard University. He used this opportunity to demonstrate the accuracy of his prophecy that *Pandalus borealis* would be found on the western side of the Atlantic in exactly the same ecological conditions in which it occurred in Norwegian waters. Through the good offices of his friend, Henry B. Bigelow, he made a cruise in the *Atlantis* off the coast of New England and found quantities of this prawn just where he expected to find it. The story is told in his paper (jointly with J. T. Ruud) in *Hvalrådets Skrifter*, No. 17 (1938). This paper contains also a study of the over-fishing problem in relation to the prawn fishery.

About Hjort's social and political views, which he held strongly, it is unnecessary to say much here; they will be found set out particularly in his Huxley Lecture and in his later books and lectures. Suffice it to say that he looked at the problems of human societies with the eye of a biologist, and that he was a strong individualist, temperamentally averse from any form of restrictive control. The old Viking spirit still lived in him. His outlook on life in his later years is well summarized in his last published lecture (*J. Conseil*, 15; April 1948), significantly entitled "The Renaissance of the Individual". Like us all, Hjort had his failings; his personality was so powerful and his views so decided that he was apt to impose them on others, and he was not very receptive of views that differed from his own. But he was a great figure whom his colleagues and friends regarded with respect, admiration and affection, even when they differed from him. E. S. RUSSELL

JOHAN HJORT was a personality in the sense that he could not be overlooked in any assembly of men; and he was a many-sided personality, man of science, philosopher, politician, diplomatist, administrator and, withal, a man of warm friendships. He had a great admiration and affection for the British race and actively sought to promote the best and closest relations between his country and ours. Of all the honours bestowed upon him, he treasured most his membership of the Royal Society.

Early in life he turned his attention to marine biology, and studied at Naples. This choice of a scientific career was almost inevitable. Norway, with its great length of coast-line and its famous seasonal fisheries for cod and herring, breeds especially seamen and fishermen. Fishing is the chief native industry of the country, and Norwegian biologists direct their attention, as one might say, automatically to the sea and all that therein is. Hjort, in particular, recognized the danger to which the fisheries were exposed by the mechanization of fishing, the ever-increasing power of mechanized fishing vessels and the rapid development of the efficiency of fishing instruments. He recognized, further, that the rational exploitation of fish stocks could be realized only in the light of wide knowledge of the complex ecology of marine life, including, of course, its physical environment. His voyage with Sir John Murray on the *Michael Sars* was one of his many excursions into this field of study.

In 1900 Hjort became director of fisheries in Norway, and in the same year began the movement, originating in Sweden, for the establishment of an international organisation for marine studies. When, in 1902, the International Council for the Exploration of the Sea was established, with its seat in Copenhagen, he was appointed Norwegian delegate, a position he occupied, in spite of his resignation of the post of director of fisheries some time after the First World War, until his death. From 1920 onwards he was one of the vice-presidents, who, with the president, constitute the Executive Committee of the Council, known as the Bureau, and, in 1938, he was elected president of the Council, a post he was about to surrender when death overtook him. Soon after the First World War he turned his attention to the machinery of the Council and, in close collaboration with the British president, devised a practical lay-out of regional and specific committees, the chairmen of which constituted a co-ordinating committee named the Consultative Committee, of which he became and, until he succeeded to the presidency, remained chairman. There is no possibility of doubt that this reorganisation of the machinery of the Council was mainly responsible for the great practical results achieved by co-operation between the member countries.

As director of the Norwegian fisheries, Hjort proved himself a competent and original administrator. He had also a wise belief in practical demonstration. When the naturalists of his department had discovered the existence in vast numbers in the deeper waters of many of the fjords of *Pandalus borealis*, now commonly referred to as the Norway prawn, the fishermen were disinclined to be interested. Hjort wasted no time in argument. He went prawn fishing, returned to harbour with a spectacular catch and dumped it on the quay. That was enough. With that practical demonstration he laid the foundation of an exceedingly profitable fishery and a flourishing export trade.

Cautious and precise as a man of science, Hjort was always apt to be impetuous in his relations with others. He had, in fact, a somewhat volcanic temperament which did not easily brook opposition. He was as apt to walk off stage as a film star, and it came about that he handed in his resignation of the post of director of fisheries in Norway once too often. The time came when the authorities did not ask him to reconsider, and accepted his resignation. But he became professor of zoology in the University of Oslo and remained a Norwegian delegate to the International Council. There, too, his volcanic temperament was sometimes active; but his fundamental friendliness always triumphed in the long run, and there is not one of his colleagues, national and international, who does not deplore the loss of a friend and a great man.

His diplomatic gifts were revealed in long and earnest endeavours to settle the vexed question, as between Norway and Great Britain, of the limits of territorial waters off the coasts of Norway. Indeed, if the last word had been with him the long negotiations would, almost certainly, have resulted in agreement; but his views were unacceptable in Norway and agreement seems to be as remote as ever. He attributed the failure to "the politicians". The trend of his political views is revealed in a remark he made to me. "No one," he said, "should be allowed to exercise the Parliamentary vote who has not passed an examination in biology, and members of Parliament, especially Ministers, should be required to have, if not a degree, at least a diploma in natural science. Then there would be no -isms, for none of the -isms will bear examination in the light of biological truth." Thus, picturesquely, he expressed the view that, inasmuch as the well-being of mankind is intimately bound up with the complex biology of all living things, political systems divorced from Nature are built on rotten foundations. But he did not believe that all wisdom was the exclusive possession of the scientific worker, as readers of "The Emperor's New Clothes" and of his Huxley Memorial Lecture, delivered in 1934, will be aware.

In recent years some of his friends have felt that his powers and, with them, his clarity of thought, were failing. But he had a long and useful life behind him, and the influence of the dynamic force he exercised in the field of science and the practical application of scientific findings will endure for generations to come. H. G. MAURICE

Mrs. Savage

MRS. E. J. SAVAGE (née Fry), whose death occurred recently, was an old student of the University College of Wales, Aberystwyth, graduating with first-class honours in botany in 1916.

Her early work concerned the "Cryptogamic Pioneer Vegetation of the Aberystwyth Shales", and later she carried out an investigation of rock floras in Caernarvon and Anglesey. She was able to add to our knowledge of the action of lichens in bringing about rock disintegration and soil formation. Several of her papers on this subject appeared in the *Annals of Botany*. During the First World War she carried out researches in anæsthetics and afterwards became a fellow of the University. In 1919, having obtained her M.Sc., she was appointed assistant lecturer in the Department of Botany at Aberystwyth. In 1925 she was appointed lecturer in botany at Westfield College, University of London, a post she held until her marriage to Mr. S. Savage, librarian and assistant secretary of the Linnean Society, in 1932. Afterwards she lived at Welwyn Garden City, where she soon became well known as an artist and miniature painter, some of her work hanging at the local art club's annual exhibition and also at the shows of the London Water Colour Society.

Mrs. Savage has left botanical records of value carefully labelled and annotated with the meticulous care she bestowed on all her work, together with the memory of a charming personality which continued to survive the heavy trials of a long illness. Her husband has the sympathy of her many friends.

LILY NEWTON

NEWS and VIEWS

Nobel Prize for Chemistry:

Prof. Arne Tiselius

THE recipient of the Nobel Prize for Chemistry this year is Prof. Arne Tiselius, who is well known to protein chemists in Great Britain. For many years he worked in the Physical Chemistry Institute of Prof. Svedberg at Uppsala, and became one of its most outstanding members. Recently a chair in biochemistry was created for him and a new Institute is in the course of construction. His greatest work, and that for which he is most widely known, was in the development of an apparatus for the electrophoretic analysis of biological substances. The apparatus, which now bears his name, has made possible accurate measurements of the electrical properties of proteins and has been most extensively applied both as a test of protein purity and to characterize the components of more complex systems. In this connexion, the application to normal and pathological sera is of great clinical importance. The apparatus is undoubtedly one of the most powerful tools ever developed in the field of protein chemistry. More recently, Prof. Tiselius has returned to the study of adsorption analysis, a subject which interested him in his earlier research years. Since the introduction of chromatography by Tswett, the method has been employed and developed on somewhat empirical lines. Prof. Tiselius and his school have studied the underlying principles involved in this type of separation and have developed elegant apparatus for the adsorption analysis of colourless substances. Many scientific men who have worked in his laboratory have benefited greatly by his patient application to their problems and by his wide knowledge. All who know him well will agree that this latest honour is indeed well deserved

Biological Service in Great Britain:

Capt. Cyril Dive

IN continuation of the announcement made in the House of Commons on April 27 that the Government accepted in principle the establishment of a Nature Conservation Board and a Biological Service under the auspices of the Agricultural Research Council, Mr Herbert Morrison on November 1 stated in the House that the preparations for the service were approaching completion, and that Capt. Cyril Diver had been appointed to take charge of it and had taken up his duties that day. The London office of the service is at Thorney House, Smith Square, S.W.1. Capt. Diver brings to his new post extensive administrative experience as clerk of the Financial Committee of the House of Commons, and in addition has long been keenly interested in natural history, and in particular the study of ecology. While on active service in the First World War he made a study of snails in the trenches. He has been an active member of the British Ecological Society, of which he has been president. He served on the Nature Reserves Investigation Committee and assisted in drafting its report, and also on the Wild Life Conservation Special Committee, which in its report recommended the formation of a Biological Service in Great Britain.

Social Studies at Sheffield: Miss Ellinor I. Black

THE University of Sheffield has recently decided to create a new School of Social Studies, which will provide a postgraduate course leading to a diploma in social studies, and other courses leading to lower qualifications. The School will be governed by a board, on which the Science as well as the Arts Faculty will be represented. As a first step to establishing the school, the University has appointed Miss Ellinor I. Black as its director. Miss Black has been associated with the Social Science Department of the University of Liverpool, which she joined in 1924 at the most critical period of its development. Since 1941 she has been a senior lecturer, and for five years during the period of the War she acted as head of the Department. In addition to the reputation she has established in Great Britain, she has also created for herself a somewhat unique position in the international field; she has since 1936 been closely connected with the Social Welfare Committee of the League of Nations, and the International Committee of Schools of Social Work. In recent months she has renewed her personal contacts with schools of social work in the United States and in Germany. Miss Black is particularly interested in the welfare of the aged. She was a member of the Old Age Survey Committee of the Nuffield Foundation, and she has carried out detailed investigations of the problem in the Merseyside area. Miss Black has made a very deep impression on the education of the professional social worker in Great Britain; as a teacher she has been able to win both the intellectual and the more personal loyalties of her students, as so many that have passed through the Liverpool School can testify. Sheffield will gain in her one who will devote herself wholeheartedly to the creation of the new institution, which will thus possess a very special human quality.

Cooled-Anode Radio Valves

THE new chairman of the Radio Section of the Institution of Electrical Engineers, Mr. F. Smith, delivered his inaugural address on October 13, under the title of "The Development and Design of Cooled-Anode Valves". The term 'cooled-anode valve' is applied to all valves having anodes which form part of the envelope, without discrimination between the different methods of cooling. Probably the earliest valve using air-cooling was the Catkin receiving valve produced in 1933, as a miniature of the then existing large water-cooled transmitting valve. When similar methods of construction were used for valves of about 60-watts dissipation, it was necessary to add a radiator with fins to the anode. The approach of the Second World War, with its demands for special short-wave transmitting valves for pulse operation, led to the development of several series of valves with external anodes cooled by a forced air draught.

Mr. Smith's address was a survey of the development during the past ten years of the various types of cooled-anode transmitting valves. The special problems associated with the use of thoriated-tungsten filaments and oxide-coated cathodes, with the glass-to-metal joints, and the construction and cooling of the electrode seals were described. As the operating-frequency was increased, special design problems were encountered in dealing with the reduced dimensions and electrode spacings. At the highest frequencies, the valve has necessarily to be regarded as an integral part of the oscillatory circuit, and this may take the form of a coaxial transmission line or resonant-cavity in some cases. Recent developments, over the whole range of valves, have continued to be chiefly in the direction of obtaining more power at higher frequencies, and of maintaining this output over a greater band of operating frequencies. The successful development of such valves with water-cooling has been a major factor in many modern radio applications.

Radio Components Exhibition in Stockholm

A PRIVATE exhibition of radio and electronic components held in Stockholm during October 18–22 was arranged by the Radio Component Manufacturers' Federation, which is a constituent association of the Radio Industry Council in Great Britain. Some thirty-seven British firms participated and showed a wide range of products, including transformers, resistors, condensers, plugs and sockets of the many different types now in use, together with chassis, cables and terminals which contribute to the assembly of modern electronic equipment. Certain classes of measuring apparatus for the testing of such equipment were also displayed.

The exhibition was opened by Mr. J. Thyne Henderson, chargé d'affaires at the British Embassy in Stockholm, and a large number of people took advantage of the invitations to attend. It was stated that many of the components and instruments had not previously been demonstrated outside Great Britain, and that it would assist British exports to Sweden to arrange this display. In conjunction with the Federation's exhibition, and at the invitation of the British Council, Dr. R. L. Smith-Rose, director of radio research in the Department of Scientific and Industrial Research, gave two lectures at the Royal Institute of Technology, Stockholm. In the first of these lectures, he described the principles of radar and the various types of radio navigational aids, while in the second he surveyed the progress made in the development of some radio and electronic techniques during the past few years.

Science Teaching at the City of London School

IN 1839 the Rev. W. Cook was appointed to the City of London School to deliver ten to twelve lectures a year on chemistry and natural philosophy, and this was considered sufficient until 1845, when the programme was increased to four lectures per week. In 1847 Thomas Hall, who was already on the staff, was appointed as lecturer, and the teaching of science in the School may be reckoned to commence from this date. On Hall's retirement in 1869, he was succeeded by Henry Durham, who had joined the staff with Isaac Scarf in the previous year. These two gave yeoman service to the School and did not retire until 1910 and 1919 respectively. They taught throughout a period when science underwent revolutionary changes, and the development of science teaching in the School kept pace accordingly. In 1869 Dr. Abbott, the headmaster, introduced science throughout the curriculum, and his successor, Mr. Pollard, founded the science side in 1892; the jubilee of the teaching of science was marked in 1897 with the Hall Memorial Scholarship. Durham was succeeded by G. C. Donington as senior science master, but the latter died soon afterwards and was replaced by G. H. J. Adlam, who died recently. In 1927 the new science laboratories were opened by the Lord Mayor of London, and they consisted of advanced and elementary laboratories, a chemistry lecture room, a balance room and a room for the science staff; soon afterwards, in 1929, a biological laboratory was completed. A further biological laboratory and a museum were added in 1937, and in 1946 the balance room was converted to an advanced physics lecture room.

The centenary of the teaching of science fell in 1947 and was celebrated at the Great Hall of the School on the afternoon of November 6 this year. There was a large gathering of officials of the Corporation, the Schools Committee, the School staff, parents, and past and present pupils, and the chief guest was the Lord Mayor and Lady Mayoress of London. The headmaster, Mr. F. R. Dale, reminded his audience that, on inspecting some laboratories, a predecessor of his, Dr. Abbott, had once said, "You and I know that this is not education". The Lord Mayor made a short address, and was followed by Sir Harold Scott, lately director of the Bureau of Hygiene and Tropical Diseases, who was himself an old pupil of the School. Various demonstrations and exhibits had been arranged in the School laboratories.

Chemistry and Chemical Technology at University College, Dublin

Mr. Michael Tierney, president of University College, Dublin, recently opened in the College a new laboratory for the teaching of chemical technology. Prof. T. S. Wheeler explained that this new laboratory would be known as the Nolan Laboratory in remembrance of the late Prof. T. J. Nolan, whose untimely death had prevented him putting into operation plans he had formulated for the teaching of chemical technology in the College. Mr. Tierney also opened a laboratory for final years honours chemistry, which will be known as the Ryan Laboratory, in remembrance of the late Prof. Hugh Ryan, the first professor of chemistry in University College, Dublin.

Bioluminescence

In connexion with Dr. V. B. Wigglesworth's article on bioluminescence in *Nature* of September 11, p. 423, Mr. K. B. Williamson, c/o Manson House, 26 Portland Place, London, W.1, has recalled observations made by him while he was malaria research officer in Malaya some years ago. A dytiscid beetle which fell about three feet off the laboratory bench on to the floor of the old Malaria Bureau, Kuala Lumpur, displayed a unique type of bioluminescence. The beetle appeared to emit bright flashes of white light, three or four at a time, from its eyes. The fluorescent type of bioluminescence is invisible even in weak light; but these flashes were conspicuous in competition with the light from a fairly bright electric bulb on the laboratory bench. The groups of flashes were repeated several times within half an hour, when the beetle was again dropped from the same height; but never afterwards, when the dropping was repeated during the subsequent months it was kept alive. In sharp contrast to another *Dytiscus*, it failed to capture any mosquito larvæ or pupæ during these months, and it not improbably died of starvation; and may have been blinded by destruction of retinal pigment and damage to the cells producing it. Mr. Williamson tentatively suggests that the flashes from the beetle's eyes were caused by reversal of the normal process of vision, energy in the form of light having been emitted instead of being absorbed by retinal pigment, as the result of intermittent outwardly directed nervous impulses, due to shock.

Earthquakes during July and August

During July, nineteen strong earthquakes occurred in various parts of the world, the strongest being of instrumental scale 7¼ and occurring off the south-west coast of Peru on July 20. It had a depth of focus of 100 km. Two earthquakes on July 16 radiating from a focus having an epicentre near the coast of Guatemala and having strengths 6½ and 6¾ were felt in Guatemala and San Salvador. The only earthquakes to do damage during the month occurred on July 20, damaging buildings on Coiba Island.

During August, twenty-four strong earthquakes occurred in various parts of the world. The strongest occurred on August 25 in the Salta Province of Argentina and attained scale 7½. During the month there was also rather more activity than usual along the south European seismic zone, earthquakes occurring on August 10 in the region of Alasehir in Turkey; on August 12, 13 and 15 near Oporto in Portugal; on August 18 near Sivrice in Turkey, and at Apulia in south Italy; on August 21, destructive at Orda Nova in south Italy; on August 22 in Portugal and Italy; and on August 27 in the region of Skadar, Albania. On August 30 there was also a repetition of an earthquake which occurred on July 8 in a rather unusual area—near Jan Mayen Island.

Group reports have been received from the United States Coast and Geodetic Survey, the central station at Strasbourg, the Jesuit seismological central station at St. Louis, United States, and individual station reports have been received from Beograd, Cleveland (Ohio), De Bilt, Durham, Kew, Stuttgart, Toledo and Uccle.

Polytetrafluoroethylene

The outstanding stability of fluorinated hydrocarbons has been fully exploited in the field of high polymers. The preparation and polymerization of tetrafluoroethylene was described some two years ago (*Ind. Eng. Chem.*, 870; 1946). The polymer (P.T.F.E.) is an excellent dielectric (power factor = 0·0002 over a wide frequency-range) and it is resistant to all common solvents up to 300° C. Molten alkali metals alone have any appreciable attack. In its strength, however, lies its greatest weakness. Form stability is retained up to 250° C., and even at higher temperatures there is no true softening; thus moulding and fabrication present major obstacles. Progress in overcoming this difficulty has, however, been made by Messrs. British Mechanical Productions, Ltd., 21 Bruton Street, London, W.1, who recently exhibited in London examples of moulded valve-holders and other components in polytetrafluoroethylene.

Pure Science and Industrial Development

In an address, "Pure Science, Fertile Source of Industrial Progress", on receiving from the Société pour l'Encouragement de l'Industrie Nationale the medal of the Grand Prix du Marquis d'Argenteuil for 1947, Prof. L. de Broglie gave a brilliant review of the contribution of research in fundamental physics to the progress of industry, in which he referred particularly to the achievements of such French physicists as D. Papin, S. Carnot, Ampère and M. Deprez. He also pleaded for the vigorous prosecution both of the investigation of the laws of Nature without reference to their application, and of industrial and technical research directed towards the utilization of scientific knowledge for the improvement of human welfare. Prof. de Broglie drew his illustrations from the fields of heat, electricity, wave mechanics, relativity and nuclear physics, indicating how discoveries and investigations which have appeared incredibly remote from practical life have yet in due course made most important contributions to industrial progress.

Sugar Research Foundation Prize

Entries are invited for the 1949 fourth intermediate prize award of 5,000 dollars offered by the Sugar Research Foundation. The award will be given for discoveries in the chemistry, physiology or technological application of carbohydrates which contribute to an understanding of the functions of sugar (sucrose) or to its practical utilization. The first of these awards (1946) was made to Drs. W. Z. Hassid, M. Doudoroff and H. A. Barker, of the University of California, Berkeley, for research leading to the enzymatic synthesis of sucrose; the second (1947) went to Dr. Carl F. Cori, professor of biochemistry, Washington University, St. Louis, Missouri, for research on problems of carbohydrate metabolism in the animal body; the third (1948) to Dr. Leslie F. Wiggins, University of Birmingham, for chemical studies of the sucrose molecule and transformations which may make sucrose a valuable raw material n the chemical industries. Winners of these intermediate annual awards are eligible for the Grand Prize of 25,000 dollars to be given in 1950 for the most important work during the five preceding years. Further particulars can be obtained from the Executive Secretary, National Science Fund, National Academy of Sciences, 2101 Constitution Avenue, N.W., Washington 25, D.C., to whom entries must be submitted by January 1, 1949.

Beilby Memorial Awards

From the interest derived from the invested capital of the Sir George Beilby Memorial Fund, at intervals o be determined by the administrators representing he Royal Institute of Chemistry, the Society of Chemical Industry, and the Institute of Metals, awards are made to British investigators in science o mark appreciation of records of distinguished work. Preference is given to investigations relating to the pecial interests of Sir George Beilby, including problems connected with fuel economy, chemical engineering and metallurgy, and awards are made generally to younger men who have done original independent work of exceptional merit over a period of years. The administrators—the presidents, honorary treasurers and secretaries of the three participating institutions—will be glad to have their attention directed to outstanding work of the nature indicated, not later than December 31, 1948. Communications should be addressed to the Convener, Sir George Beilby Memorial Fund, Royal Institute of Chemistry, 30 Russell Square, London, W.C.1.

"Changing Aspects of Nutrition"

An article under this title in *Nature*, October 2, pp. 543 and 544, dealt with the proceedings of a discussion on September 9 in Section I (Physiology) of the British Association. In the report of Dr. J. W. Howie's contribution, reference is made to a "protein rice concentrate"; this should read "protein-rich concentrate". Ewes fed this concentrate as a supplement to pasture grazing showed, over a period of two years observation, no difference in fæces worm-egg counts from similar ewes grazed on the same pasture but not fed concentrate. Lambs born of the ewes and fed the same diet as their mothers, however, showed a marked difference in worm burden during a year's observation, the lambs given concentrate having significantly fewer worm eggs in the fæces. The account of Dr. Howie's second experiment, in which diet was shown to influence the resistance of mice to experimental tuberculosis, may have suggested that the higher protein in the better diet was established as the cause of the superior resistance. Dr. Howie wishes to make it clear that he has not yet examined this possibility, and that other important differences between the diets must be taken into account.

Announcements

The Meldola Medal is the gift of the Society of Maccabæans and is normally awarded annually. The next award will be made early in 1949 to the chemist who, being a British subject and less than thirty years of age on December 31, 1948, shows the most promise, as indicated by his or her published chemical work brought to the notice of the Council of the Royal Institute of Chemistry before December 31, 1948. Communications should be addressed to the President, Royal Institute of Chemistry, 30 Russell Square, London, W.C.1, the envelope being marked "Meldola Medal".

A symposium on the "Applications of Electronics to Research and Industry" has been arranged by the Electronics Group of the Scientific Instrument Manufacturers' Association. It will be held at the Caxton Hall, London, during November 18 and 19.

A fund for the encouragement of the gliding and soaring movement is being raised as a tribute to the late Robert Kronfeld, who was killed while testing a tailless glider early this year. A committee has been formed to make the appeal and receive subscriptions, which should be sent to Mr. Lawrence Wingfield, c/o Royal Aeronautical Society, 4 Hamilton Place, W.1, marked Kronfeld Memorial Fund.

A half-yearly list of botanical papers printed in India, Pakistan, Burma, Ceylon, Siam, Malaya and Indonesia will be published by the Botanical Society of Bengal in the Society's *Bulletin* issued in April and October every year. Authors are requested to send their reprints to the Honorary Secretary, Botanical Society of Bengal, 35 Ballygunge Circular Road, Calcutta 13.

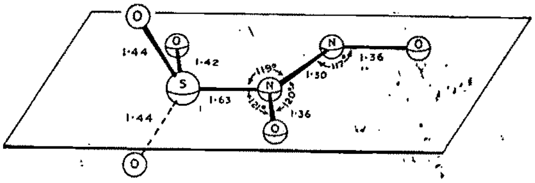
LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications

Structure of the Dinitrososulphite Ion

SINCE the observation by Davy[1] that nitric oxide is absorbed by alkaline potassium sulphite to form a crystalline compound (shown later by Pelouze[2] to have the composition $K_2SO_5N_2$), several conflicting formulæ have been suggested to account for its chemistry[3-6].

We have found that the corresponding thallium and ammonium salts are isomorphous with the potassium salt, and this has enabled us, by direct X-ray crystal analysis, to determine the structure of the dinitrososulphite ion independently of any preconceived formulation. The results of Fourier syntheses show the configuration of the ion to be as in the accompanying figure.



An interesting feature of the structure is that the S atom and the N_2O_2 group lie in one plane and that the bond-angles approximate closely to 120°. This, together with the short N—N distance of 1·30 A., implies, as suggested by Evans and Gergely (see following communication), a double-bond between the nitrogen atoms with trigonal [sp^2] hybridization. It invites comparison with the structure of dimethyl nitramine[7]. Both the N—O distances of 1·36 A. correspond to a bond-order of about 1·2 if compared with the most recently suggested covalent radii[8,9].

As was to be expected (cf. the structure of the sulphamate ion[10]), the SO_3 and the adjoining nitrogen atom form an approximately tetrahedral group, with S—O = 1·44 A. and S—N = 1·63 A.

Although three-dimensional methods were used in the structure analysis, we cannot at this stage exclude the possibility of the bond-lengths being subject to errors up to ± 0·06 A., owing to the large absorption errors unavoidable in intensity measurements with the potassium salt. The isomorphous ammonium salt will be used to obtain more exact values for the atomic parameters.

We wish to thank Mr. F. J. Garrick and Mr. A. White for the preparation and chemical analysis of the thallium salt.

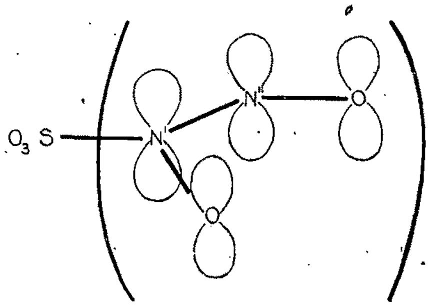
THE trigonal planar symmetry of the three bonds formed by the nitrogen atom attached to the sulphu atom in the structure described in the preceding communication, suggests that the orbitals of this nitrogen atom correspond in bond formation to a hybridization of the type $(1s)^2(2p)^2(2s2p^2)^3$ rather than to $(1s)^2(2s)^2 2p_x 2p_y 2p_z$. In the former electronic configuration, the three sp^2 orbitals will possess trigonal symmetry, and there will be one doubly occupied π-orbital orthogonal to the plane of the sp^2-orbitals. This type of hybridization has been postulated by us[1] in a discussion of the properties of the >N—H O=C< structure in proteins.



We have based molecular orbital calculations on the structure shown in the accompanying illustration, in which the π-orbitals are occupied by six electrons, the whole group within the brackets having a full negative charge. Since the SO_3 group has a tetrahedral structure, it appears reasonable to neglect conjugation of this group with the π-electrons of the nitrogen and oxygen atoms; we have therefore dealt with the four atomic centres in the structure within the brackets

The secular equation for this array of centres is

$$\begin{vmatrix} q_O - E & \beta_{ON'} & 0 & 0 \\ \beta_{ON'} & q_{N'} - E & \beta_{N'N''} & 0 \\ 0 & \beta_{N'N''} & q_{N''} - E & \beta_{N''O} \\ 0 & 0 & \beta_{N''O} & q_O - E \end{vmatrix} = 0$$

where the β's stand for exchange integrals and th q's for Coulombic integrals.

The ionization potential[2] and thus the Coulombi integral of the trigonal nitrogen N′ is lower than tha of the pyramidal nitrogen N″. Since all the β's ar very nearly the same, a difference between $q_{N'}$ an $q_{N''}$ of the order of the difference in the ionizatio potentials would lead to a structure with unequa NO bond-distances. The inductive effect of the sulphu atom of the SO_3 group on the N′ to which it i attached, must, however, be taken into account, an because of the symmetry of the structure we hav assumed that this effect offsets the difference in th q's.

We find the following values for the charg densities and the bond-orders:

Atom	O		N′		N″		O
Charge	− 0·724		+ 0·724		− 0·276		− 0·72
Bond-order		1·45		1·72		1·45	

when $q_{N'} = q_{N''} = q_O$

Atom	O		N′		N″		O
Charge	− 0·84		+ 0·84		− 0·16		− 0·84
Bond-order		1·40		1·76		1·40	

when $q_{N'} = q_{N''}$, and $q_O - q_N = 0·5$.

It is interesting to compare these results with th experimental values reported above. For this purpos we have used the covalent radii given by Gordy[3] t construct a bond-order – bond-length curve for NN and NO bonds. On this basis we can make the following comparison:

Bond	Bond-order calculated	Bond-length (A.) calculated	Bond-length (A.) observed
ON	1·45	1·32	1·36
	1·40	1·33	
NN	1·72	1·30	1·30
	1·76	1·29	

The undistorted angle N′N″O should be close to 90°, and we suggest that the observed angle of 117° arises because of the strong repulsion between the negatively charged oxygen atoms.

The same treatment can be applied to the dimethylnitramine structure[4], and, although owing to hyperconjugation with the methyl groups the simplifications are less justified, the results do reveal strong double-bond character in both the NN and the NO bonds.

Crystal Structure of 'Gammexane'

The crystal structure of γ-benzenehexachloride, the insecticide 'Gammexane', has been determined by X-ray analysis (Weissenberg diagram) in the usual way of trial and error, starting from Patterson data and supported by repeated Fourier syntheses. Cell dimensions: $a = 8{\cdot}5$ A.; $b = 10{\cdot}3$ A.; $c = 13{\cdot}9$ A.; $\beta = 121°$. Space group $P2_{1/c}$; four molecules per cell.

Fig. 1. Projection of the electron density on a plane perpendicular to the a-axis. ($z' = z \sin \beta$)

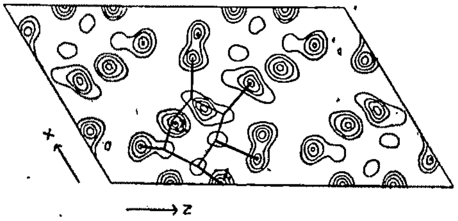

Fig. 2. Projection of the electron density along the b-axis

Figs. 1 and 2 give the Fourier map of the 100 and 010 projections. The carbon ring is of the 'chair'-form and the configuration of the chlorine atoms proves to be of type εεεϰϰϰ (in the nomenclature of Hassel[1]), as is seen in Fig. 3.

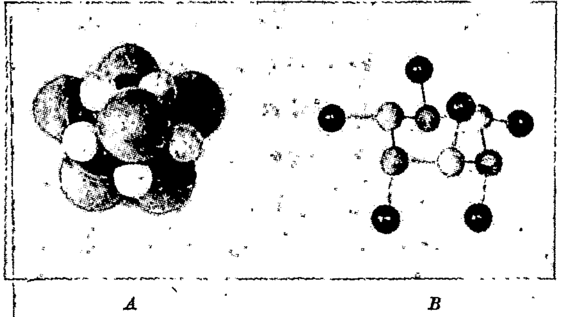

Fig. 3. Atomic models of the 'Gammexane' molecule. *A*, All dimensions to scale (small white balls represent hydrogen atoms). *B*, Schematic (hydrogen atoms omitted)

Thus the molecule of the insecticide is shown to be not isomorphous with the molecule of meso-inosite (type εϰϰϰϰϰ), contrary to a suggestion by Slade[2]. Moreover, it has been generally supposed that steric hindrance should not allow chlorine atoms in 1,3 positions both to have the ε-configuration[2,3].

This, too, is disposed of by our result. The steric hindrance causes only a slight bending apart of the 1,3 C—Cl bonds in question (see Fig. 2, where the projections of these bonds are not of equal length). The number of isomers is now no longer restricted to five; and as a matter of fact, Hassel quite recently announced the preparation of a sixth isomer[4].

A High-Pressure Hydrogen-filled Ionization Chamber

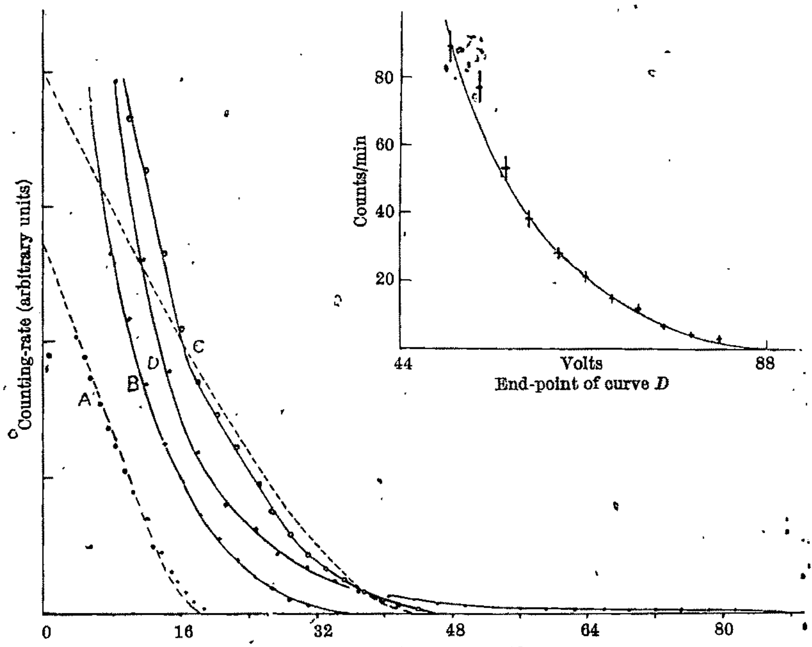
Electron collection has been obtained in hydrogen up to pressures of about 90 atmospheres. To get the very pure hydrogen needed, a cylindrical ionization chamber was made of glass (12 cm. long; 5 cm. diameter), with an axial wire (0·2 mm. diameter), for the collecting electrode; a coating of 'Aquadag' on the outside of the glass formed a convenient high-voltage electrode. The chamber was very carefully evacuated, baked, sealed off, and then placed in a steel container in which the pressure of hydrogen was slowly raised at the rate of one atmosphere per hour. By means of two heated palladium tubes sealed into the glass chamber, the chamber was slowly filled with purified hydrogen.

The size of recoil proton pulses produced by neutron irradiation was found to decrease with increase in pressure. At 60 atmospheres and 4,000 volts, the pulse size was very nearly independent of collecting voltage, but only 0·32 times that expected for complete electron collection. At 88 atmospheres the pulse size had decreased to 0·18 times the expected value.

To check whether, in spite of the electron loss, all pulses were still proportional to the initial ionization, the chamber was irradiated with neutrons produced by the known (*d,n*) reactions in hydrogen-2, beryllium-9, nitrogen-14[1] and lithium-7[2]. The respective neutron energies are 2·2, 4·14, 5·32, 13·05 MeV., that is, in the ratio 1 : 1·88 : 2·42 : 5·94. The maximum pulse sizes were found to be (see graph) in the ratio 1 : 1·9 : 2·4 : 4·7. The low measured value for the 13 MeV. neutron group may be due to the small intensity. The end-point does, in fact, agree well with the more intense 10 MeV. group (the ratio then is 1 : 4·55). Bias curves calculated from the known chamber geometry are shown (broken lines) for the homogeneous neutrons from hydrogen-2, and from nitrogen-14. Agreement is good, and the small deviations may be due to lack of complete voltage saturation, the effect of valve noise, and a known slight inhomogeneity in the neutrons produced by a thick target and by scattering in the target assembly.

With a pulse-size analyser[3], or a pulse spectrograph[4], the present chamber should be useful for measuring neutron spectra up to approximately 13 MeV., the limiting factor being the range of the proton recoils. An important advantage is the high efficiency for neutron detection. For example, at 90 atmospheres the present chamber will detect 17 per cent of incident neutrons of 2·2 MeV.

In view of the freedom from electronegative gas contamination and the lack of electron attachment in hydrogen, it is unlikely that the electron loss can be explained by volume recombination or negative ion formation. Moreover, such electron loss would seriously distort the bias curves. It must therefore be attributed to preferential or initial recombination. The magnitude of the effect is surprisingly large.



Curve *A*: ²H + D neutrons Curve *C*: ¹⁴N + D neutrons
Curve *B*: ⁹Be + D neutrons Curve *D*: ⁷Li + D neutrons

Curve *A* was obtained at 60 atmospheres pressure, the remaining three at 88 atmospheres. The abscissæ in curve *A* have been scaled down by a factor 0·18/0·32 = 0·57, to allow for the difference in pressure. The break in the upper part of curve *C* shows the presence of some ²H + D neutrons

It is hoped to fill a similar chamber with deuterium and use it for studies of the nuclear photo-effect.

Masses of Mesons

IN 1929 I published a number of papers[1] on the problem of the masses of the fundamental particles, in which I proposed a new principle, called the "hypothesis of elementary indeterminacy". According to this hypothesis, a fundamental neutral particle is ascribed a certain fundamental length, q_0, related to a fundamental momentum, p_0, by the relation

$$q_0 p_0 = h, \qquad (1)$$

and a fundamental time, t_0, connected to the energy, E_0, by the conjugate relation

$$t_0 E_0 = h. \qquad (2)$$

q_0 is interpreted as the linear dimension of a cell structure of the configuration space of the particle; this amounts to the assertion that the position of the particle cannot be determined to a greater accuracy than q_0, so that this quantity constitutes the linear extension or 'radius' of the particle. t_0 is interpreted as a natural time unit connected with the particle, which is essentially the same as ascribing to it an oscillation of periodic time t_0.

Applying this hypothesis first to photons, one has to put $t_0 = 1/\nu$, which immediately leads to $E_0 = h\nu$. Further, one has to put $p_0 = h\nu/c$, which leads to $q_0 = \lambda$; thus the 'radius' of the photon is identical with the wave-length of the corresponding wave. Next, applying the hypothesis to a stationary particle of rest mass m_0, one finds with the help of the Einstein relation $E_0 = m_0 c^2$,

$$t_0 = \frac{h}{m_0 c^2}, \qquad (3)$$

which is equivalent to the de Broglie relation $h\nu_0 = m_0 c^2$ for the de Broglie frequency of the particle. One can further show that

$$q_0 = \frac{h}{m_0 c}. \qquad (4)$$

In other words, the linear dimension or radius of the particle turns out to be equal to its Compton wave-length.

In the previously mentioned papers the attempt was made to obtain the mass ratio of proton and electron from this hypothesis on the basis of the derived formulæ by considering the transformation of a neutron into a proton and an electron (β-decay) at a time when the neutron had not actually been discovered[2]. It led to a very satisfactory value for this mass ratio. In the present note, the hypothesis is applied to the problem of the masses of the mesons.

From (4) one obtains for the radius r_n of the neutron

$$r_n = \frac{h}{m_p c}, \tag{5}$$

where the neutron mass is replaced by the almost equal mass m_p of the proton. On the other hand, this radius can also be defined as the range of the nuclear field surrounding the neutron which, according to Yukawa's theory, is roughly given by

$$a = \frac{h}{2\pi m_\pi c}, \tag{6}$$

where m_π is the mass of the meson connected with this field, which is most probably a π-meson. Identifying (5) and (6), one gets at once

$$m_p/m_\pi = 2\pi. \tag{7}$$

This gives for the mass number of the π-meson in electronic units the value 293, which compares well with the experimentally established value[3] 260 ± 40.

It is well known that the π-meson is in many ways analogous to a photon. Thus the production of such a meson by a fast nucleon is the analogue of the *Bremsstrahlung* of an electron, and the nuclear disintegration caused by a π-meson is the analogue of the ionization of an atom by a photon or the photo-electric effect. It is suggested here that the 'decay process' of a π-meson into a μ-meson is, in fact, the analogue of the Compton effect. In other words, it is assumed that the collision of a π-meson with a nucleon (neutron) results in the production of a μ-meson, the remainder of the energy being disposed of by the emission of some neutral particle of small rest mass (neutretto, neutrino or photon).

The maximum change of wave-length for the ordinary Compton effect is given by

$$\lambda' - \lambda = \frac{2h}{m_e c}. \tag{8}$$

In the analogous case of the 'meson Compton effect', we have to replace the 'radii' λ′, λ of the photons by the radii

$$r' = \frac{h}{m_\mu c}, \quad r = \frac{h}{m_\pi c}, \tag{9}$$

of the primary and the secondary mesons, and the electronic mass m_e is to be replaced by m_p. This with the help of (7) leads to

$$m_\pi/m_\mu = 1 + \frac{1}{\pi} = 1 \cdot 32. \tag{10}$$

The results of the experimental determination of the mass ratio m_π/m_μ by the Bristol school is considerably higher, near 1·6; but recent results by American workers, reported at the Bristol Symposium on Cosmic Radiation, indicate a value near 1·35, which is in agreement with formula (10).

This 'scattering' process could, of course, be repeated and would result in the production of smaller and smaller mesons. Indeed, the existence of mesons of small mass (or of some sort of 'heavy electrons') has been claimed recently by a number of workers in the field of cosmic radiation. Furthermore, if the close analogy between mesons and photons is correct, all mesons are, in fact, the same type of fundamental particle, and one should therefore expect to find a continuous spectrum of mesons over a wide range of masses below and above that of the π-meson.

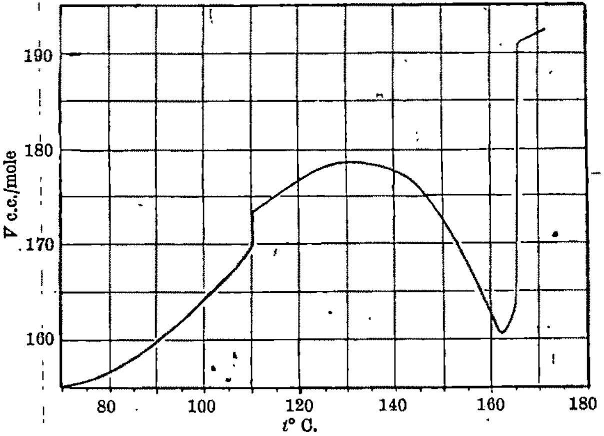
Volume Change of Hexamethyl Benzene

SINCE the crystal structure of hexamethyl benzene at room temperatures has been accurately determined by Robertson and Brockway[1], it seemed of interest to investigate the intra- and inter-molecular interactions of the methyl groups. Pauling[2] has suggested that a lower transition point at − 165° C. marks the beginning of rotation of methyl groups. It is then desirable to elucidate the mechanism of an upper transition found at 110° C. The thermal data of these transitions as well as those of the melting point have been reported by Parks and his co-workers[3]. We have made a preliminary dilatometric investigation of this substance from room temperature to the liquid temperature. The results are shown in the accompanying graph.



Throughout the whole region of temperature, except the transition and melting temperatures, the heating-rate is about 0·2° C. per minute, and at the melting and transition points the temperature was kept constant for about two or three hours in order to reach the equilibrium state. The molecular volumes are calculated by subtracting the expansion of mercury which is used as the dilatometer liquid. The volume expansion from room temperature to just below the transition point is about 10·2 per cent, which is comparable with the density decrease of 9 per cent suggested by Robertson and Brockway as likely to occur if the triclinic crystal had taken a monoclinic structure by a slight rearrangement. The abrupt volume change at the transition point is 3·65 c.c./mole, corresponding to about 2·4 per cent of the volume at room temperatures. After passing through the transition point, the volume still increases to a conspicuous maximum value (178·5 c.c./mole) at about 130° C. and then decreases to a minimum value (160·5 c.c./mole), showing negative thermal expansion, melting finally at 165·5° C. The volume change at the melting point is about 30 c.c./mole, corresponding to 8 per cent of the volume at room temperatures.

The ratio of entropy changes at the transition and melting points measured by Parks and others is nearly equal to the ratio of the corresponding volume changes given above. Examples of similar unusual negative thermal expansion are known in the cases of ammonium iodide[4] (— 60° C. $\sim$ — 40° C.), deutero-ammonium bromide (ND_4Br)[5] (— 70° C. $\sim$ — 58° C.), ice[6] under the pressures of about 1,500 kgm./cm.^{2} (— 10° C. $\sim$ — 2° C.), and a few other substances in the neighbourhood of their transition points. We are now making an X-ray analysis of the structure in the region between the transition and the melting points. The examination of the effect of substitution of the methyl groups by chlorine atoms will also be interesting in connexion with the dielectric study by White and Bishop[7].

Nitrogen Afterglow

IN a recent communication in *Nature*, L. Herman and R. Herman[1] have given an account of their spectroscopic study of the complex afterglow in nitrogen immediately after the discharge is stopped. These short-lived afterglows have also been extensively studied by Kaplan[2]. In this connexion, Herman and Herman remark that it seems difficult to explain the characteristics of the complex afterglow as recorded by them with the help of the theory of active nitrogen proposed by me[3]. It appears, however, that these authors have missed the very important point that my theory was developed for the long-lived Lewis – Rayleigh afterglow, and not for the short-lived Kaplan afterglow, which is quite a distinct phenomenon. According to my hypothesis, the Lewis – Rayleigh afterglow phenomena, for example, the long life, the rate of decay, ionization, the characteristic spectrum (selected bands from the first positive group), etc., can be very satisfactorily explained if it is assumed that the active substance in the glow is $N_2^+(X')$ ions. The Kaplan afterglows, however, contain besides $N_2^+(X')$ ions other particles such as $N_2^+(A')$, N, N′ which are responsible for the complex nature of the short-lived spectrum. It may, however, be mentioned in this connexion that in some of his experiments Kaplan has observed the persistence of the first negative bands for several seconds after the discharge is stopped. This provides a direct proof of the presence of N_2^+ ions, at least in the first stage of the afterglow. According to my hypothesis, the N_2^+ ions continue their existence even after the short-lived afterglows have died out and produce the phenomena associated with the Lewis – Rayleigh afterglow.

For explaining the afterglow characteristics M. and Mme. Herman prefer the Cario – Kaplan mechanism[4]. This necessitates the presence of atomic nitrogen. There is no doubt that nitrogen molecules (N_2) are dissociated in the strong discharge and excited nitrogen atoms are produced. This, indeed, is proved by some of Kaplan's spectrograms[5]. But the presence of such atoms when the discharge is on, or for a very short time thereafter, is a different matter from their persistence for several hours producing the Lewis – Rayleigh afterglow, remembering that atomic nitrogen is known to have very short life.

Evolution of the Universe

IN checking the results presented by Gamow in his recent article on "The Evolution of the Universe" [*Nature* of October 30, p. 680], we found that his expression for matter-density suffers from the following errors: (1) an error of not taking into account the magnetic moments in Eq. (7) for the capture cross-section, (2) an error in estimating the value of α by integrating the equations for deuteron formation (the use of an electronic analogue computer leads to $\alpha = 1$), and (3) an arithmetical error in evaluating ρ_0 from Eq. (9). In addition, the coefficient in Eq. (3) is 1·52 rather than 2·14. Correcting for these errors, we find

$$\rho_{\text{mat.}} = \frac{4 \cdot 83 \times 10^{-4}}{t^{3/2}}.$$

The condensation-mass obtained from this corrected density comes out not much different from Gamow's original estimate. However, the intersection point $\rho_{\text{mat.}} = \rho_{\text{rad.}}$ occurs at $t = 8 \cdot 6 \times 10^{17}$ sec. $\cong 3 \times 10^{10}$ years (that is, about ten times the present age of the universe). This indicates that, in finding the intersection, one should not neglect the curvature term in the general equation of the expanding universe. In other words, the formation of condensations must have taken place when the expansion was becoming linear with time.

Accordingly, we have integrated analytically the exact expression[1]:

$$\frac{dl}{dt} = \left[\frac{8\pi G}{3}\left(\frac{aT^4}{c^2} + \rho_{\text{mat.}}\right)l^2 - \frac{c^2 l_0^{\,2}}{R_0^{\,2}}\right]^{1/2},$$

with $T \propto 1/l$ and $R_0 = 1{\cdot}9 \times 10^8 \sqrt{-1}$, light-years. The integrated values of $\rho_{\text{mat.}}$ and $\rho_{\text{rad.}}$ intersect at a reasonable time, namely, $3{\cdot}5 \times 10^{14}$ sec. $\cong 10^7$ years, and the masses and radii of condensations at this time become, according to the Jeans' criterion, $M_c = 3{\cdot}8 \times 10^7$ sun masses, and $R_c = 1{\cdot}1 \times 10^3$ light-years. The temperature of the gas at the time of condensation was 600° K., and the temperature in the universe at the present time is found to be about 5° K.

We hope to publish the details of these calculations in the near future.

Our thanks are due to Dr. G. Gamow for the proposal of the topic and his constant encouragement during the process of error-hunting. We wish also to thank Dr. J. W. Follin, jun., for his kindness in performing the integrations required for the determination of α, on a Reeves Analogue Computer. Relative Abundances of Potassium and Argon in the Earth's Surface Materials

E. Bleuler and M. Gabriel[1] have recently shown that potassium-40 decays radioactively in two different ways. Apparently a potassium-40 nucleus can decay either by emitting a beta-ray, or by capturing one of its own *K*-electrons and emitting a gamma-ray. In the first case the resulting product is calcium-40, and the latter argon-40. 1·9 capture processes occur for every beta-ray emission.

The beta-ray emission of potassium-40 has been known for many years, and the accepted half-life of the reaction is $(7 \pm 1) \times 10^8$ yr. The effect of the *K*-electron capture process is to reduce the total half-life of potassium-40 to about $2{\cdot}4 \times 10^8$ yr. E. Gleditsch and T. Graf[2] have pointed out the importance of this fact in geophysical theory, and have shown, for example, that the heating effect of potassium-40 in the earth's crust $2{\cdot}4 \times 10^9$ years ago must have been about two hundred times greater than the total radioactive heating at the present day. So far as I am aware, however, the problem of the amount of argon-40 which would have been produced by the reaction in the life-time of the earth has not been considered.

Potassium is an abundant element in the earth's surface materials. If, following F. W. Clarke[3], we consider an outer spherical shell of the earth 10 miles deep, its composition is: atmosphere, 0·03 per cent; ocean, 7·08 per cent; solid crust, 92·80 per cent. The total percentage of potassium is about 2·4, and since the relative abundance of potassium-40 in natural potassium[4] is 0·012 per cent, the present percentage of potassium-40 in the shell is $1{\cdot}2 \times 10^{-4} \times 2{\cdot}4 = 2{\cdot}9 \times 10^{-4}$ per cent. Argon constitutes about 1·44 per cent of the atmosphere by mass; hence its percentage in the total shell is $0{\cdot}03 \times 1{\cdot}44 \times 10^{-2} = 4{\cdot}3 \times 10^{-4}$ per cent, or 1·5 the present amount of potassium-40.

If we take a figure of $2{\cdot}4 \times 10^9$ years as a reasonable estimate of the age of the crust, it follows that the original amount of potassium-40 would have been 2^{10}, or about 1,000 times greater than the present amount. Of this quantity, approximately two-thirds would have been transformed to argon; that is, the total quantity of argon present in the surface materials of the earth should be about 430 times the known amount of argon in the atmosphere.

It might be assumed that the bulk of the argon generated in the solid crust was retained in the crust, but even this assumption will only reduce the discrepancy. From the quantity of sodium retained in the ocean, F. W. Clarke[5] estimates that an amount of solid material equal to about 5 per cent of the postulated shell has undergone erosion. It is hard to imagine that, if during this process the sodium was extracted from the rock, the argon would not also escape, and this process would supply a quantity of argon more than twenty times that of atmospheric argon. If, on the other hand, we assume that the argon of the atmosphere[4], which is 99·6 per cent A^{40}, is derived from the eroded layer only, we easily arrive at an age of the crust of about $1{\cdot}3 \times 10^9$ years, which differs by a factor of about 2 from the accepted estimates of geological ages. A correction to these results should be applied for the amount of argon in solution in the ocean; but it can easily be shown that this correction is of no importance.

Two other possibilities may be considered: (1) that argon-40 is itself unstable and changes to some other element; or (2) that argon escapes from the atmosphere into space. Both processes seem to be highly improbable. At the lower end of the periodic table, the mass defect of the stable elements increases with atomic number, and this consideration alone seems to rule out the decay of argon-40 to any other stable element. Apart from this, argon is very commonly used in Wilson cloud chambers, and it is highly unlikely that its hypothetical decay would have escaped detection. The escape of argon from the atmosphere would seem also to involve the escape of nitrogen, oxygen and probably carbon dioxide. This seems very unlikely.

It is known, however, that cosmic rays produce atomic disintegrations; but again it can be shown that the amount of argon which could be destroyed by this process is probably exceedingly small. It is estimated by Powell and his co-workers that, at a height of 3,000 m., fifteen explosive atomic disintegrations occur per c.c. per diem in a nuclear photographic emulsion. This means that in $2{\cdot}4 \times 10^9$ years, $1{\cdot}3 \times 10^{13}$ atoms per c.c. would have been disintegrated, assuming, of course, that the cosmic ray intensity remained constant. There are, however, nearly 10^{23} atoms per c.c. of the emulsion; hence about one atom in 10^{10} of the emulsion would disintegrate. The effect on the average chemical composition of the emulsion is obviously insignificant. Argon, owing to its distribution throughout the atmosphere, may behave in a different manner; but it seems improbable that a factor of at least 10^9 could be introduced. Also we are faced with the problem of disposing of the large quantities of helium and hydrogen which would result from the destruction of the argon. These, of course, might escape from the atmosphere.

We are accordingly forced to conclude that either the assumed data for the breakdown of potassium-40 and its abundance in the surface materials are incorrect, or that the present estimates of the age of the earth are too great by a factor of two, unless some plausible explanation of the clash of data can be found.

Since writing the above, H. E. Suess[6] has published a letter in which he arrives at a similar result. He concludes that the proposed half-life of 2 × 10^8 yr. for potassium-40 must be incorrect.

Structure of the Pigment of *Chromobacterium iodinum*

The dihydroxyphenazine obtained by catalytic reduction of the pigment of *Chromobacterium iodinum*[1] has been methylated. The resulting dimethoxyphenazine crystallized in yellow needles, m.p. 245–246° (found: C, 69·9; H, 4·4; $C_{14}H_{12}O_2N_2$ requires C, 70·0; H, 5·0 per cent). This compound differs from 1 : 4-dimethoxyphenazine[2], m.p. 185°. It has been shown already that synthetic 1 : 2- and 1 : 3-dihydroxyphenazines[3,4] differ from the natural product. The conclusion, therefore, is that the pigment contains the two hydroxyl groups in different benzene nuclei of the phenazine skeleton.

The condensation of 3-methoxy-*o*-quinone with 3-methoxy-*o*-phenylenediamine has yielded a mixture of 1 : 5- and 1 : 8-dimethoxyphenazines which was separated by chromatography, yielding:

(*a*) Yellow needles, m.p. 245–246°, not depressed by admixture with the dimethoxy phenazine described above (found: C, 70·4; H, 4·7; $C_{14}H_{12}O_2N_2$ requires C, 70·0; H, 5·0 per cent). The crystalline forms of the two specimens are identical.

(*b*) Yellow, hair-like needles, m.p. 253–254° (found: C, 70·2; H, 4·7; $C_{14}H_{12}O_2N_2$ requires C, 70·0; H, 5·0 per cent).

The problem of the orientation of the two methoxyl groups in (*a*) is now being investigated, and a full account of our work will be published elsewhere.

Preparation of Phthalyl-L-Glutamic Acid

In a recent paper recording the preparation and properties of phthalyl-amino-acids, Billman and Harting[1] claim that the derivative obtained by heating L-glutamic acid with phthalic anhydride at 180–185° is the optically active phthalyl-L-glutamic acid.

While investigating the use of phthalylated intermediates as a means of synthesizing simple peptides containing glutamic acid, we have prepared both phthalyl-L-glutamic acid, m.p. 158–159°, $[\alpha]_D^{18°}$ in 0·33*N* sodium carbonate = −27·4° (found: C, 56·5; H, 4·0; N, 4·9; $C_{13}H_{11}O_6N$ requires C, 56·3; H, 4·0; N, 5·1 per cent), and the corresponding racemic acid, m.p. 189–190° (found: C, 56·5; H, 4·0; N, 5·0 per cent). The American authors have not quoted the rotation of their phthalylglutamic acid; but it is evident from its melting point of 188–189° that the derivative described by them is the DL-compound. However, we have repeated their preparation, and although the crude product has measurable optical activity, we have confirmed our earlier observation that the only compound which can be isolated on recrystallization is the racemic acid of melting point 189–190°. Phthalyl-DL-glutamic acid is more satisfactorily prepared by heating phthalic anhydride and a suspension of L-glutamic acid in boiling pyridine. The crude phthalamic acid obtained on evaporating the solvent is then heated with acetic anhydride to close the phthalimide ring, dehydration of the glutamic acid residue occurring simultaneously with the formation of phthalyl-DL-glutamic anhydride. From this the DL-acid is obtained simply by dissolving in warm water.

In order to avoid racemization, which may be due to oxazolone formation under the influence of the acetic anhydride, it is necessary to use a glutamic ester, for example, diethyl L-glutamate, which reacts with phthalic anhydride in cold ether. From the precipitated product, diethyl phthalyl-L-glutamate is readily obtained by the action of thionyl chloride, and hydrolysis with boiling 2*N* acid gives the phthalyl-L-glutamic acid, m.p. 158–159°.

Both phthalyl-DL-glutamic anhydride and the corresponding L-compound have been condensed with various amino-compounds, including amino-acids, and from the products the phthalyl group has been removed, under conditions which leave the peptide linkages intact, by an adaptation—already considerably exploited[2]—of the well-known hydrazine method.

A full account of these experiments will be published in due course.

Note added on October 22.—Phthalylglutamic anhydride differs from other acylglutamic anhydrides, for example, carbobenzoxy-L-glutamic anhydride, in reacting with ammonia to form the γ-amide, thus affording a direct synthesis of glutamine. Evidence for this important difference is found in the degradation of the phthalyl derivative with sodium hypobromite, eventually to 1 : 3-diaminobutyric acid, and in the evolution in the van Slyke estimation of 98 per cent of the nitrogen content of the product obtained after removing the phthalyl group.

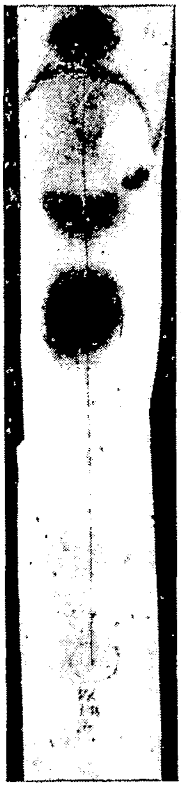
Paper Chromatography of the Noble Metals

The separation of amino-acids by partition chromatography on paper was first described by Consden, Gordon and Martin[1]. A large number of separations of organic compounds has been described since then. I have recently discovered that cations can be separated successfully if the solvent is adjusted suitably to prevent hydrolysis. The solvent selected for study was butanol saturated with *N* aqueous hydrochloric acid.



In this communication the separation of gold, platinum, palladium, copper and silver is described, which in the ordinary method of fire assaying is a tedious process, and, owing to the small amounts available for analysis, is an example where paper chromatography is eminently superior to chemical methods of analysis.

A mixture or alloy of the metals is dissolved in aqua regia. The solution is then diluted with an equal volume of water and one drop used for the chromatogram. The technique used is that of Williams and Kirby[2]: A cylinder of No. 1 Whatman paper, 28 cm. high and 26 cm. wide, is used, and drops of the solution to be analysed are placed 2·5 cm. from the bottom of the cylinder and marked in pencil. The cylinder is developed by letting it stand for 20–24 hours in a dish of butanol saturated with *N* hydrochloric acid inside a 5-gallon crock in an atmosphere saturated with *N* hydrochloric acid and butanol.

On ascent, two liquid fronts are formed, one being the front of dehydrated butanol and the second being the front of the aqueous phase, which follows about 4–6 cm. below. Since the aqueous front has a dark border, which does not fade on drying, this is used as reference for R_F values, and if a substance is extracted into the upper butanol layer it will have an R_F value of more than one.

The separation takes place as shown in the accompanying illustration. Silver is deposited on the point where the drop is applied ($R_F = 0$). Copper travels slowly ($R_F = 0{\cdot}1$). Palladium has an R_F value of 0·6, platinum of 0·72–0·80, gold of 1·05–1·13.

The spots of gold and platinum are yellow and that of palladium is orange. For the purpose of the illustration the paper was held over ammonia and then over hydrogen sulphide, producing a dark brown spot for gold and palladium and a lighter brown spot for platinum. Copper forms a black spot, which fades on drying, and silver also forms a black spot. Gold forms a tail of colloidal gold; but the amount lost is minute, as can be seen readily.

The method here described has the great advantage of separating amounts of the order of 0·1 mgm. and less of the metals quantitatively, and may supersede other methods used for the separation of these metals.

This communication is intended to be a preliminary report in the field of inorganic paper chromatography. Work on the copper and tin groups has already been completed and will be described soon. The other metals are at present under investigation; also the suitability of chromatography for large-scale preparations is being tried.

A Fourth Order Reaction

IN a study of the reactions of metal complexes with hydrogen peroxide, in particular the system Fe^{3+}, $\alpha\alpha'$-dipyridyl which gives the "Katalasestoss" reported by Kuhn and Wassermann[1], we found it necessary to obtain data on the equilibrium and kinetics of formation of the red ferrous complex ion, $\mathrm{Fe(Dipy)_3}^{2+}$, formed according to the reaction:

$$\mathrm{Fe}^{2+} + 3\,\mathrm{Dipy} \rightarrow \mathrm{Fe(Dipy)_3}^{2+}.$$

A recent publication[2] shows that, so far as the equilibrium is concerned, the analogous complex with *o*-phenanthroline has many similar features.

The concentrations of $\mathrm{Fe(Dipy)_3}^{2+}$ in our experiments were measured colorimetrically. Its formation is an extremely fast reaction above *p*H 5 even when the concentrations of both reactants are 10^{-5} *M*. The rate is less in more acid solutions, and can be measured easily at *p*H 2–4. At *p*H 2–3 a large excess of the base can be used, in which case the reaction is first order with respect to Fe^{2+}. The first-order constants at different dipyridyl concentrations are found to be proportional to the cube of this concentration and inversely proportional to the cube of the hydrogen ion concentration; this dependence can be accounted for if only the free base reacts and not its conjugate acid, the pyridyl pyridinium ion $(\mathrm{Dipy.H})^{+}$. At *p*H 3–6, where comparable concentrations of Fe^{2+} and base had to be used to get measurable rates, the concentration-time data fit the expression for a fourth-order reaction. When the reaction goes to completion, the following rate equation holds over the entire *p*H range 2–6:

$$\frac{d}{dt}[\mathrm{Fe(Dipy)_3}^{2+}] = k_0\,[\mathrm{Fe}^{2+}]\ \mathrm{Dipy}]^3 = k_t\,[\mathrm{Fe}^{2+}]\,[\mathrm{Dipy}]^3\left(\frac{K_a}{K_a + \mathrm{H}^{+}}\right)^3, \qquad (1)$$

where k_0 is the observed velocity constant (*p*H-dependent), k_t the rate constant for the reaction between Fe^{2+} and free base, and K_a the dissociation constant of its conjugate acid. At 17° C. and $\mu = 0{\cdot}025$, $k_t = 9 \times 10^{14}$ $\mathrm{l.}^3$ $\mathrm{m.}^{-3}$ $\mathrm{min.}^{-1}$ and $K_a = 4{\cdot}2 \times 10^{-5}$. The value of K_a determined kinetically from (1) agrees well with the value we have obtained by *p*H titration experiments, which show in addition that $\alpha\alpha'$-dipyridyl is a mono-acid base (see ref. 2). Determinations of K_a at different temperatures give a heat of dissociation of 2·0 k.cal. for the conjugate acid.

In view of the improbability of four-body collisions, we propose the following mechanism involving two rapid successive equilibria and a final rate-determining step:

$$\mathrm{Fe}^{2+} + \mathrm{Dipy} \underset{}{\overset{K_1}{\rightleftarrows}} \mathrm{Fe(Dipy)}^{2+} \qquad \text{(i)}$$

$$\mathrm{Fe(Dipy)}^{2+} + \mathrm{Dipy} \overset{K_2}{\rightleftarrows} \mathrm{Fe(Dipy)_2}^{2+} \qquad \text{(ii)}$$

$$\mathrm{Fe(Dipy)_2}^{2+} + \mathrm{Dipy} \underset{k_f}{\overset{k_b}{\rightleftarrows}} \mathrm{Fe(Dipy)_3}^{2+} \qquad \text{(iii)}$$

where K_1 and K_2 are equilibrium constants and k_f and k_b are forward- and back-rate constants. When the reaction goes to completion, k_b can be neglected, and provided the concentrations of $\mathrm{Fe(Dipy)}^{2+}$ and $\mathrm{Fe(Dipy)_2}^{2+}$ are small, the above rate equation (1) follows. With this mechanism, k_t in equation (1) becomes $K_1K_2k_f$. Evidence that intermediates play a part in the reaction is afforded by our observation that with an excess of Fe^{2+} over base, the reaction does *not* go to completion even at pH 6·0, although it does so with equivalent concentrations. For example, with $3 \times 10^{-5} M$ dipyridyl and $6 \times 10^{-4} M$ Fe^{2+}, only 80 per cent of the possible amount of $\mathrm{Fe(Dipy)_3}^{2+}$ is formed. Using the above equilibria, it can be shown that, provided $[\mathrm{Fe}^{2+}] > 1/2K_1$, an increase in the $[\mathrm{Fe}^{2+}]$ will decrease the amount of $\mathrm{Fe(Dipy)_3}^{2+}$ formed.

Measurements of k_0 and K_a at different temperatures show that k_t, that is, $K_1K_2k_f$, is independent of temperature. This indicates that the heats of formation of the intermediate complexes and the activation energy for the formation of $\mathrm{Fe(Dipy)_3}^{2+}$ from $\mathrm{Fe(Dipy)_2}^{2+}$ are either all zero or cancel out.

In sufficiently acid solution not all the available Fe^{2+} is converted into the complex, even when dipyridyl is in excess. This is due to the low concentration of free base, and makes possible a determination of the overall equilibrium constant. This has the form:

$$K = \frac{[\mathrm{Fe(Dipy)_3}^{2+}]}{[\mathrm{Fe}^{2+}]\,[\mathrm{Dipy}]^3} \cdot \left(\frac{K_a + \mathrm{H}^+}{K_a}\right)^3,$$

where $K = K_1K_2k_f/k_b$. We find $K = 4 \times 10^{17}\ \mathrm{l.^3\,m.^{-3}}$ at 17° C., and $\mu = 0{\cdot}025$.

It was of interest to examine the dissociation of the complex, for we had observed fading of the colour in strong acids. This is presumably the reverse of reaction (iii) brought about by the removal of free base. The reaction is first order, but the constant is dependent on the acid used (hydrochloric, sulphuric or perchloric), and also on its concentration. Thus it increases from 6×10^{-3} to 10×10^{-3} min.$^{-1}$ as the acid goes from $0{\cdot}25\,N$ to $0{\cdot}5\,N$, reaching a steady value of about 12×10^{-3} min.$^{-1}$ for hydrochloric and sulphuric acids and about 9×10^{-3} for perchloric acid, all at 17° C. This value, combined with k_t for the forward reaction, gives a kinetic value of about 9×10^{16} for the overall equilibrium constant K, and compares as well as can be expected with the direct determination given above. The back reaction is very dependent on temperature, having an activation energy of about 28 k.cal. The dependence on the acid and its concentration, which is at variance with the above scheme, is being examined further. A full account of this work will be published elsewhere. The investigations are being extended to tripyridyl and tetrapyridyl complexes and their reactions with hydrogen peroxide.

Occurrence of a Phosphate Ester of a Hydroxyamino-Acid

DURING a recent investigation of the dialysate of calf embryo muscle juice by means of paper chromatography, a very slow-moving spot has been noticed which does not appear to correspond with any substance previously recognized in such extracts. Fractionation of the dialysate on chromatograms of amberlite *I.R.*4 indicated that it was due to a weakly acidic substance: It was eluted from these chromatograms in the same fraction as phosphoryl aminoethanol, which, contrary to the finding of Outhouse[1], appears to be present in calf embryos. Thus it seemed worth investigating whether the unknown substance might be another phosphoric ester. This was done as follows.

The fraction from the amberlite column was separated on a one-dimensional paper chromatogram, using phenol/ammonia as solvent. By means of the 'washing off method' of Consden, Gordon and Martin[2], the substance in question was removed from the paper without treatment with ninhydrin. One sample thus obtained was hydrolysed with $6\,N$ hydrochloric acid at 100° for 24 hours and was then again subjected to paper chromatography. Two strong spots were formed, one being due to unchanged material, and the other having R_f values in phenol/ammonia and collidine similar to those of hydroxylysine. A second sample was treated at pH 8–9 with the phosphatase from rat intestinal mucosa. After chromatography, the only strong spot formed had the rate expected for hydroxylysine. Certain weak spots which are difficult to identify appeared both here and on the chromatogram of the acid hydrolysate. A third sample was also treated with the phosphatase, but in this case sulphuric acid, sodium molybdate and stannous chloride solutions were added in the proportions given by Kuttner and Lichtenstein[3]. A blue colour was formed. These three experiments indicate that the original substance is a difficultly hydrolysable phosphate ester.

In order to identify further the substance which appeared to be similar to hydroxylysine, an enzyme hydrolysate obtained as above was subjected to chromatography with phenol in an atmosphere containing acetic acid. As expected, the spot obtained had moved very much slower than in phenol/ammonia. This behaviour is regarded as characteristic of basic substances. Finally, another sample was run as a mixed chromatogram in phenol/ammonia with and without authentic hydroxylysine. The specimen used was obtained from Dr. C. Dent, who received it from Dr. D. D. van Slyke; sincere thanks are due to both. No separation was obtained. Therefore it seems most likely that the original spot must be due to a phosphate ester of hydroxylysine. In view of the possible similarity of this substance with that recently reported by Chargaff[4] as being present in an acid hydrolysate of ox-brain phosphatides, it seemed worth while to publish these findings at the present stage.

This work was done while I was holding a fellowship from the Donner Foundation, to which thanks are due.

Antagonism between Basic Compounds (Spermine, Streptomycin) and Basic Bactericidal Substances

THE following bactericidal substances—trypaflavine ($5 \times 10^{-4} M$), methylene blue ($1 \times 10^{-3} M$), protamine sulphate ($2{\cdot}5 \times 10^{-4} M$), chinine ($2{\cdot}5 \times 10^{-3}$) and crystal violet ($1 \times 10^{-4} M$)—cause a strong and progressive inhibition of the respiration of bakers' yeast, suspended in glucose phosphate at 28° C. (cf. also ref. 1). Spermine and streptomycin, though also basic substances, even at high concentrations ($1 \times 10^{-2} M$ and $1 \times 10^{-2} M$ respectively) do not affect the respiration of yeast and thus have no direct bactericidal activity. It can be shown that all these substances, the inhibitors as well as spermine and streptomycine, compete for the same negative components of the yeast cell, when brought in contact with a yeast suspension[2].

According to Dubos[3] bactericidal substances such as basic dyes owe their bactericidal activity to two properties: the basicity or positive charge of the cation and the relatively large molecular weight, favouring the formation of sparingly soluble and feebly ionized compounds with negatively charged components of the bacterial cells.

Since all the substances we used are basic and have high molecular weight (protamine sulphate) or a relatively high molecular weight (spermine, trypaflavine, methylene blue, chinine, streptomycin, crystal violet), one wonders why some of these substances show a direct bactericidal activity and others not, the more that we have proved that they all compete for the same components of the bacterial cell[2]. Which is the property that the bactericidal substances possess and that spermine and streptomycin do not share?

It seems to us that a property described by Michaelis[4] for the basic dyes should be taken into account, namely, the occurrence of dimers, trimers and polymers in solutions of those substances. This polymerization is dependent upon the concentration. It is counteracted by the fact that these substances possess the same positive charge; but this aggregation or polymerization is, of course, favoured when the positive charges are held by negative components of the cell. It is evident that polymerization increases the effective molecular weight.

Why should we not admit that basic substances will show direct bactericidal activity when possessing a real high molecular weight, as is the case for protamine sulphate, or achieve a high molecular weight at definite concentrations by aggregation of their organic residues, the positive charges (cause of repulsion) being held by negatively charged components of the cells? This would be the case for methylene blue, trypaflavine, chinine and crystal violet, but not for spermine and streptomycin.

It might be expected that streptomycin and spermine, competing by virtue of their basicity with the bactericidal substances, but not being toxic, would be able to counteract the inhibition of respiration caused by these last substances. We have proved now that this is really the case: spermine at definite concentrations completely reverses the inhibition of respiration caused by trypaflavine, methylene blue, chinine, crystal violet and protamine; for example, in the presence of $2 \times 10^{-4} M$ spermine, trypaflavine ($2 \times 10^{-4} M$) does not cause any inhibition under the conditions of our experiments. For streptomycin we were obliged to limit our observations to methylene blue and trypaflavine, but here, too, the reversal was complete; thus in the presence of $1 \times 10^{-3} M$ streptomycin, methylene blue ($1 \times 10^{-3} M$) leaves the respiration of bakers' yeast untouched. Our experiments with spermine recall those of Silverman and Evans[5], who found that the toxic effect of atebrine upon the growth of *E. coli* is antagonized by spermine and other naturally occurring amines, but these authors postulated a growth-factor activity of these amines.

All our experiments were made at 28° C. by means of the Warburg apparatus, with yeast suspensions in glucose-phosphate medium (10 mgm. fresh bakers' yeast in a final volume of 2 ml.).

Full experimental details will be published in *Archives internationales de Pharmacodynamie et de Thérapie*.

We are indebted for several of the compounds used (spermine, clupeine sulphate) to the firm of Hofman-Laroche (Basle).

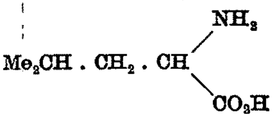
Structure of the Antibacterial Compound, Aspergillic Acid

REDUCTION of aspergillic acid, $C_{12}H_{20}O_2N_2$, an antibiotic isolated from culture filtrates of *Aspergillus flavus*[1], gives in high yield a neutral reaction product, deoxyaspergillic acid, $C_{12}H_{20}ON_2$, to which the structure 2-hydroxy-3 : 6-di*sec*.-butylpyrazine has been ascribed[2]. We have previously described syntheses of 2-hydroxy-3 : 6-di*sec*.-butylpyrazine[3], and although we were unable to resolve the racemic compound, a comparison of its properties with those of deoxyaspergillic acid led us to conclude that the latter is a hydroxypyrazine derivative. Substantial differences in the intensity of light absorption in the ultra-violet, however, suggested that the two compounds differ more profoundly than in stereochemical orientation. Moreover, deoxyaspergillic acid has been racemized by treatment with alkali, and the racemate is distinct from 2-hydroxy-3 : 6-di*sec*.-butylpyrazine, which is itself unaffected by similar treatment with alkali.

Treatment of aspergillic acid with bromine followed by reduction of the bromo-substitution product with zinc and acetic acid[2] gives a product, $C_{12}H_{22}O_2N_2$. We find that hydrolysis of the compound $C_{12}H_{22}O_2N_2$ with hydrobromic acid gives a mixture of two α-amino-acids. Separation of the component α-amino-acids was achieved by fractional solution of



$Me_2CH\,.\,CH_2\,.\,CH(NH_2)CO_2H$

the mixed copper salts in water and methanol. Regeneration of the parent acid from the less soluble copper salt gave DL-leucine (I), identified as its 3 : 5-dinitrobenzoyl-derivative and by its degradation with ninhydrin to *iso*valeraldehyde. Regeneration of the acid from the more soluble copper salt gave *iso*leucine (or allo*iso*leucine, II), identified by its degradation to methylethylacetaldehyde by means of ninhydrin. The compound $C_{12}H_{22}O_2N_2$ is therefore an optically active leucyl*iso*leucine anhydride (III), deoxyaspergillic acid is either 2-hydroxy-3-*iso*butyl-6-*sec.*-butylpyrazine (IV) or 2-hydroxy-3-*sec.*-butyl-6-*iso*butylpyrazine (V), and aspergillic acid is either (VI) or (VII).

Toxicity of Sulphydryl Compounds to Seeds

Audus and Quastel[1] have recently shown that sodium thiosulphate is toxic to seeds of higher plants, and it has been reported[2] that sodium ethyl xanthate is being used commercially as a weed-killer. The accompanying table shows the results of tests for toxicity to wheat seeds of a number of sulphydryl compounds, and may therefore be of interest.

Root fresh weight as per cent of control

Group	Substance	Concentration 0·0005*M*	Concentration 0·005*M*	Concentration 0·05*M*
A	thioacetic acid	77	—	—
,,	potassium thiocyanate	96	79	27
,,	sodium thiosulphate	81	79	39
,,	potassium dithio-oxalate	95	90	not tested
,,	potassium methyl dithiocarbonate	50	—	—
,,	potassium ethyl xanthate	90	83	—
B	*n*-propyl mercaptan	101	97	82
,,	*i*-propyl mercaptan	95	104	90
,,	ethyl mercaptan	94	75	27
,,	phenyl mercaptan	80	38	—
,,	cysteine hydrochloride	110	45	16
,,	thioglycollic acid	81	45	—
,,	*o*-thiolbenzoic acid	89	81	51

Wheat seeds were sown on tap-water agar containing the toxic agents in Petri dishes and incubated for four days at 24° C. The roots from each seed were then cut off and their fresh weight determined. Although most of the compounds tested showed some degree of toxicity, thioacetic acid and potassium methyl dithiocarbonate were outstanding in their toxicity; this has been confirmed in other experiments.

It has been suggested[3-5] that the biological activity of ethylenic compounds is greatest where the substituent groups are electron-attracting. Walsh[6] has commented on the similarity between —S— and —CH=CH—. We thought it possible, therefore, that the activity of sulphydryl compounds might be similarly explained. Ferric chloride gives colours with compounds of the type *R*SH and their salts. We have observed that the nature of the group *R* determines the colour. Groups, the phenyl derivatives of which give *meta* substitution when acted on by cationoid reagents, that is, groups which attract electrons, give red colours when their —SH compounds are treated with ferric chloride in water, ethanol or glacial acetic acid; the compounds listed in group *A* in the table fall into this category. *R*SH compounds with *R*-groups the phenyl derivatives of which give *ortho* or *para* substitution give green or blue colours with ferric chloride in water or alcohol and no colour in glacial acetic acid; those compounds listed in group *B* in the table fall into this category.

Though the most active two compounds, thioacetic acid and potassium methyl dithiocarbonate fall into the group with *R*-substituents of high electron affinity, there is no general tendency for those compounds with *R*-substituents of high electron affinity to be more toxic than those with *R*-groups of low electron affinity. An explanation of the variation in toxicity among these sulphydryl compounds has therefore, yet to be found.

The Very Rare *Rh* Genotype R_yr (*CdE*/*cde*) in a Case of Erythroblastosis fœtalis

In a case of erythroblastosis fœtalis, the mother was found to belong to the rare *Rh* phenotype which includes the genotype $R'R''$. *Rh*-typing of her family makes it clear that the genotype is, in fact, *CdE*/*cde* or R_yr (or, in the latest nomenclature of Dr. Wiener, r^yr). The combination *CdE* has never previously been clearly demonstrated[1-5]. The claim of Stancu, Clark and Snyder[6] to have discovered *CdE* seems insufficiently documented for so important a claim.

Fisher[7] first stated that the combination *CdE* should be capable of existence. He and Race afterwards suggested[8] that its frequency in the English population would probably be less than 0·005 per cent, and that of the genotype *CdE*/*cde*, about 37 per million.

The case described is that of Mrs. K., whose seventh pregnancy ended at 7½ months in the birth of a baby which became severely jaundiced and died on the fourth day of kernicterus.

Mrs. K.'s blood group is *O MN P*; her red cells are, moreover, agglutinated by anti-*C* and anti-*E* but not by anti-*D*. Her serum contains both complete and incomplete anti-*D*. The blood of the husband is not available as he is abroad; he is known to be *D* positive. Mrs. K.'s mother and her third child are of the same rare *Rh* type (*CdE*) as herself. The *Rh* types of all members of the family who have been tested are given in Fig. 1, in terms of their reactions with anti-*C*, anti-*D* and anti-*E* sera.

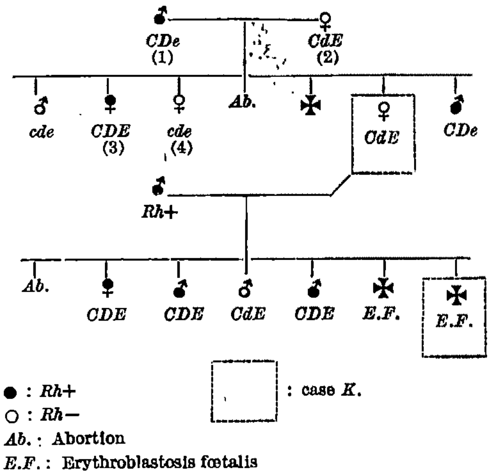

Fig. 1. The *Rh* types of Mrs. K. and her relatives (tested with anti-*C*, anti-*D* and anti-*E* sera)

Two sibs of Mrs. K. are *Rh* negative (*cde*/*cde*). Their parents must, therefore, both be heterozygous, with the combination *cde* on one chromosome. It is thus possible to fix the genotypes of all the surviving members of two generations of the family as shown in Fig. 2, and to identify *CdE* as an inherited combination on one chromosome. Race's table of antigen-antibody reactions can thus be completed (Fig. 3).

Only anti-*C*, anti-*D* and anti-*E* sera were available for most of the tests; Mrs. K.'s parents were, in addition, tested with anti-c kindly supplied by Dr. J. J. Van Loghem, jun., of the Centraal Laboratorium Bloedtransfusiedienst van het Nederlandsche Roode Kruis, Amsterdam. Mrs. K. and her children are now abroad and are not available for further tests.

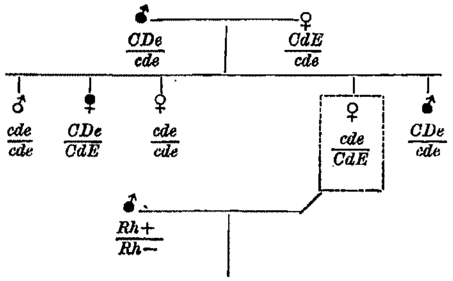

Fig. 2. The *Rh* genotypes of Mrs. K. and her relatives

		cDe	*cde*	*cDE*	*cdE*	*CDe*	*Cde*	*CDE*	*CdE*
		Rh_0	*rh*	Rh_2	*Rh″*	Rh_1	*Rh′*	Rh_z	Rh_y
Anti-*C*	Anti-*Rh′*	−	−	−	−	+	+	+	+
Anti-*D*	Anti-Rh_0	+	−	+	−	+	−	+	−
Anti-*E*	Anti-*Rh″*	−	−	+	+	−	−	+	+
Anti-*c*	Serum St.	+	+	+	+	−	−	−	−
Anti-*d*		−	+	−	+	−	+	−	+
Anti-*e*		+	+	−	−	+	+	−	−

Fig. 3. Fisher's synthesis of the *Rh* system

Gene combinations and their reactions with different antisera. The data within the inner line had been established by Race and Taylor by the end of 1943 and were the basis of the complete scheme proposed by Fisher. Murray, Race and Taylor[9] announced in 1945 the reactions of R_z with anti-*D* and anti-*E*. Mourant later in 1945 described anti-*e*. Diamond[10] in 1946 announced his discovery of anti-*d*, and this antibody was fully described by Hill and Haberman[11] in 1948. The discovery of R_y and its reactions are described in the present paper.

Dr. J. J. Van Loghem, jun., checked the *CdE* type of Mrs. K. and the presence of antibodies in her serum. Miss E. W. Ikin and Mrs. J. Woodward in the laboratory of Dr. A. E. Mourant in London carried out full *Rh* tests on the blood of Mrs. K. and her sibs (3) and (4) with the following results:

	Anti-*C*	Anti-*D*	Anti-*E*	Anti-*c*	Anti-*e*
Mrs. K.	+	−	+	+	+
(3)	+	+	+	−	+ (titre 1)
(4)	−	−	−	+	+ (titre 8)

Our data prove the existence of the combination *CdE* on one chromosome. Thus the eighth allelic combination *CdE* of Fisher's theory is recognized, and this ingenious synthesis may be considered as completely confirmed.

Cryptic Polyploidy and Variation of Chromosome Number in *Ribes nigrum*

THE examination of meristems in root tips and young ovules in the c_2-generation bushes grown from seed of colchicine-induced tetraploid *Ribes nigrum* ($2n = 32$) showed that the chromosome number varies greatly from one to another. The lowest number found was 4, all numbers between 4 and 32 being observed. Statistics on the frequency of the different chromosome numbers shows that the distribution is in its main features binomial, the peak lying at the diploid number $2n = 16$. All numbers divisible by four are more frequent than might be expected on random distribution.

If we accept the axiom that the haploid chromosome set is the smallest chromosome combination for the viability of an individual cell[1], we may assume on the basis of the above observations that the primary haploid chromosome number of the genus is $x = 4$, the recent species being accordingly derived tetraploids. This is in accordance with Stebbins' hypothesis[2,3] that many woody plants which have been regarded as diploid actually are polyploid. The meiosis of certain *Ribes* hybrids[4] indicates that hybridization and amphidiploidy have played a part in the speciation of this genus. The formation of two separate and independent spindles in one cell has been established as the cause of the variation in the chromosome number. The original chromosome complement is divided between the two spindles. The autonomy of the separately dividing groups is to be found already in the resting nucleus, which in this case is more or less constricted. Between the mitotic cycles of the two chromosome groups synchronization disturbances are relatively common.

The occurrence of the split spindle and the timing disturbances in the divisions are assumed to be connected with structural changes in the chromosomes arising during the colchicine treatment[5]. Chromosomes are then broken, especially in the heterochromatic segments[6]. The amount of heterochromatin is thus variable, and consequently the nucleic acid metabolism is unbalanced. It seems to be a pertinent fact that structural changes disturb the balance of the mitotic genes[7] which regulate the nuclear cycle.

The occurrence of the diploids ($2n = 16$) in the progeny of the tetraploid bushes proves that the hypoploid cells also affect the offspring. As Upcott[8] has proposed in the corresponding case of *Primula kewensis*, a strong selection seems, however, to be effective among hypoploid cells. Only the most viable chromosome combinations are able to survive as functioning gametes.

Aural Sensitivity and Heart Beats

MOST mains-actuated radio receivers when switched on have a greater or lesser degree of mains hum, which is readily audible so long as the programme is inaudible. With my own receiver I have always been conscious of a rhythmic pulsation in intensity under these conditions, which I have been inclined to attribute to some slight lack of balance in the electrical components of the set. On inquiry, I find that many people are aware of this rhythmic effect.

When burning damp logs on the fire during last winter, I noticed a similar rhythmic pulsation in the sound emitted by steam escaping from the ends of the logs, as well as in the even higher-pitched hiss produced when drops of water from the wood fell on to the hot bars, the effect being slightly more marked in the latter case. Later, I noticed that the mains hum pulsation of the radio receiver coincided in time with that from the fire. On feeling my pulse (or temporal artery) I discovered that the rhythm was that of the heart-beat, the intensity of the sound heard diminishing in each case for the duration of the 'beat'. When their attention was directed to the effect, I found that other people also noticed the same rhythmic pulsation of intensity with the heart-beat. I have noticed the same effect with the hiss of an oxyacetylene welder, with the sound of water flowing through the supply pipes when water has been drawn from the main tank, with waves breaking on the seashore, and in other cases.

There seemed little doubt that the effect must be connected in some way with the ear-drum. Since the drum is richly supplied with blood vessels, it follows that, corresponding to each surge of blood through the arteries, the drum will swell slightly and have increased inertia, so that its amplitude of vibration under constant stimulation will be reduced. Thus when we are listening to a continuous source of sound of uniform intensity, an apparent diminution in intensity will be observed for the duration of each 'beat', and between beats the intensity will be greater and sensibly uniform.

Experiments with a beat-frequency oscillator fed to a pair of headphones were then carried out to see if the effect depends in any way on frequency. Whether the headphones were on the head or off (but still audible), no essential difference in the pulsation effect was noticeable at frequencies from 50 c./s. to the limit of audibility (14,000 c./s. for my left ear, and 12,000 c./s. for my right). Near the upper limit of audibility, however, the effect was distinctly more marked relatively than at somewha lower frequencies, as it had been found to be with the hiss from water on the hot fire-bars as compared with the sound of steam issuing from the logs burning in the fire. At any given frequency, the audible effec was practically independent of the intensity of the sound, except that above the threshold of pain found it impossible to detect any pulsation.

It was further observed that, when listening to a constant source of sound, the apparent intensity wa reduced by biting the teeth firmly together, especially at higher frequencies. By performing this action rhythmically, a pulsation in intensity analogous to that produced by heart-beats was readily detectable. This effect also took place at all frequencies and fo all intensities below the threshold of pain. It seems likely that it is caused by a variation in tension of the drum effected by the muscular effort of biting.

Finally, when sitting alone in a very quiet room at night, I find that I can actually hear my heart-beats. The sound is very faint indeed and resembles gasping. It seems reasonable to suppose that it is caused by the movements conveyed to the malleus by the ear-drum as it enlarges at each surge of blood through the arteries. The effect may be slightly accentuated by resonance in the external auditory meatus.

These results may be of interest in considerations of the minimum perceptible energy in the auditory process[1]. I am indebted for information to several scientific colleagues, and in particular to Dr. E. T. B. Francis, of the Department of Zoology.

"Freedom and Obligations"

THE leading article, "Freedom and Obligations", in *Nature* of October 2, p. 507, contains a criticism of a charter for men of science, drafted by the Committee on Science and its Social Relations at its meeting in Paris during June 15–16. As two of the persons responsible for this draft, we wish to make the following observations.

We certainly are aware that freedom and rights cannot be defined in an absolute way, and that any formulation of them will bear references to the circumstances among which we are living. We also know, all of us, that we have obligations to fulfil. But we are convinced that time and again particular aspects of freedom must be brought to the foreground, in order to make clear the way present trends are deviating from what once was considered as the ideal of science, namely, free and open discussion of all outcome of research, as the best safeguard that science may serve mankind as a whole.

In the discussion at our meeting we did not overlook the position of scientific workers in industry. We are of opinion, however, that the sentence in the article in *Nature*, "The freedom of publication and freedom to discuss his work with other men of science must in industry be subject to some limitations", is an expression of a situation accepted in a certain historical period, but cannot be considered as a rule to which science should be subjected as a matter of principle. We believe that industrial enterprises should be considered and managed as 'public utilities', and that the idea of competition in view of the commercial aspects of industry cannot remain, in the long run, a guiding principle for the development of human society. We have not gone so far as was suggested by Prof. A. V. Hill in an address delivered on February 17, 1946, when he suggested that it should be a duty of scientific workers to refuse to co-operate in tasks in which they, or their representatives, are not allowed a reasonable share or partnership in the responsibility of deciding on the purpose, policy or probable result of their work. Neither did we ask, in the charter we drafted, for information on every detailed purpose. But we think it indispensable in the present period that every scientific worker should know whether his work is intended directly to serve the public welfare, or whether it should serve profit motives or purposes of competition, or military purposes, in order that he may realize in what position he finds himself with regard to his fellow citizens, and that he may consult his conscience in this respect.

It was mentioned at the meeting of our Committee that free discussion of work in progress cannot yet be always and everywhere allowed; but it was unanimously agreed that the charter should ask for publication of all results, and that freedom of discussion should be restricted as little as may be possible. We are well aware that in many enterprises such freedom will not be given at the present moment; nevertheless, we believe that it is necessary to remind scientific workers of what must be our goal and to stimulate fighting for this goal. We are afraid that otherwise the human mind—particularly in present circumstances—is too much apt to acquiesce in conditions which (to put it mildly) should be described as a return to the 'enlightened despotism' of the eighteenth century.

With regard to measures prescribed for scientific workers by Government institutions, we certainly do not profess disloyalty; but again we consider it a duty of scientific workers to have a clear idea of what is asked from them and for what purpose this is asked. We also believe that much open discussion is desirable and possible in connexion with the problem whether the present trends for enforcing secrecy do not go too far, and whether much of the present tension in the world would not have been reduced had not this unhappy trend for secrecy taken hold of it and stirred up fear and suspicion.

As regards the problem of loyalties overriding national loyalties, which is brought forward in the article in *Nature*, we do not wish to refer to political creeds which certainly are often misleading many people; but it may be remembered that the Roman Empire persecuted the early Christians likewise because they professed a higher loyalty than that to the State. Surely it will be accepted that both the idea that man has to consult his conscience in order to know his responsibility to God as his first duty, and the idea of a brotherhood extending over all national frontiers, have been a gain in the development of civilization. It may be true that international loyalty in the present world seems to have little force; but this should not prevent us from fighting for it in a domain of human activities which some time ago appeared to offer a unique ground for its development.

Scientific workers themselves must decide whether they will accept, as suggested in *Nature*, "the practice of the most advanced countries as a standard and as the most satisfactory solution to the problem"; we believe it to be important to point out clearly that there are aims reaching further, and that in the light of these aims the practice of the countries mentioned also may be critically analysed.

We realize that most of what has been brought forward here by us will not have the same weight for everybody; but we wanted to state that such problems as have been mentioned in the article in *Nature* had indeed been before us. We should like to add that we consider the article in *Nature* a valuable contribution to a discussion which we can only welcome, and it is to be hoped that it may call forward comments from various sides.

RIVER RESEARCH IN EAST AFRICA

By Dr. VERNON D. van SOMEREN, M.B.E.

An important step forward in the conservation and development of the river fisheries in East Africa was taken on September 11, when the Governor of Kenya Colony, His Excellency Sir Philip Mitchell, formally opened the River Research and Development Centre near Nyeri Station in Kenya, in the presence of many people connected with fish and fishery problems.

Financed by grants from the Kenya Government and the Development and Reconstruction Authority of the Colony, this Centre has been built by the Kenya Game Department under the direction of the fish warden, Mr. Hugh Copley. The Centre consists of a research laboratory, a trout hatchery, and an administration centre situated on the banks of the Upper Sagana River, on the lower slopes of Mount Kenya. The staff at present consists of one biologist (Dr. V. D. van Someren), one assistant fish warden (Major D. F. Smith) and a hatchery superintendent, the whole being administered by the head offices of the Game Department in Nairobi.

The function of the Centre is twofold, namely, river fishery research and practical fish breeding, neither of which has hitherto been investigated scientifically in the Colony. On the fishery research side, the first object is to provide a scientific background for developing the trout fishery resources of East Africa. Both rainbow and brown trout were first introduced to Kenya about forty years ago, and since then the trout fisheries have been developed as a considerable sporting and tourist asset, most of the rivers now being stocked. The practical management of these fisheries has so far been run successfully on an *ad hoc* basis; but it has been felt for some time now that any further advance must be based on scientific research into river productivity and fishery management. Deterioration in growth-rate of trout, for example, has taken place in several of the rivers since their initial stocking, and this is but one aspect of the problem which is being investigated. Afterwards, such research will be carried further to investigate fully the indigenous fisheries of the lower reaches of the rivers where trout will not live. In some rivers there exist native fisheries for *Tilapia*, *Barbus*, eels, catfish and the like, and research would undoubtedly improve the yield of such food fish for the African population.

Other research aspects of the Centre's work include the large-scale systematic rearing of aquatic insect nymphs and larvæ, since the majority of such in East African rivers are as yet unnamed. The food productivity per unit area of river bottom is being investigated in relation to the population of fish. The food and growth-rate of the fish themselves are also under study, and the rivers present many interesting ecological features in the distribution of fish and other aquatic life, since they may rise at an altitude up to 14,000 ft. and finally discharge at sea-level.

It is the intention that this Centre should work in close co-operation with the Wray Castle Laboratory of the Freshwater Biological Association in England, and to this end Dr. Winifred Frost, of the Wray Laboratory, has already spent six months working at the Centre on East African river eels and trout fisheries. Close liaison will also be maintained with the East Africa Inland Fishery Research Institute at Jinja in Uganda, now in course of construction, and it is possible that amalgamation of the two may later take place, with the added advantage of staff interchange.

On the educational side, short vacation courses in freshwater biology will be held for pupils of the Kenya secondary schools and probably also for African biology students from Makerere College in Uganda. The first vacation course for girls of the Kenya High School has already taken place.

The laboratory has accommodation for visiting scientific workers, and it is hoped that students from overseas will take advantage of the facilities to study, not only fishery problems, but also other aspects of the biological, physical and chemical phenomena in East African rivers. Guest-house accommodation has been provided for such visitors at the Centre.

Practical trout breeding will go hand-in-hand with research, the hatchery being designed to accommodate up to 150,000 ova. This is the first such hatchery to be built in East Africa, and will serve the three East African territories and farther afield if required. Some of the first batch of fry reared have already been sent to the Sudan. Biological work in connexion with the proposed Government fish culture farm for indigenous fish will also be undertaken.

The biology, breeding and growth of fish and other aquatic life in these high-altitude regions, with a sub-tropical climate and little variation in seasons, present many interesting problems compared with temperate climates. Over a period of years, the results of research should be not only of practical economic importance but also of fundamental biological interest.

ROAD RESEARCH IN SCOTLAND

As an initial step in the founding of a Scottish branch at East Kilbride, near Glasgow, of the Road Research Laboratory, were a conference and exhibition held at the Royal Technical College, Glasgow, on September 24, under the auspices of the Road Research Organisation of the Department of Scientific and Industrial Research in association with the Institution of Civil Engineers (Glasgow and District Association), the Institution of Municipal Engineers (Scottish Branch), the County Surveyors' Society (Scottish Branch) and the Scottish Accident Prevention Council. Sir Patrick Dollan presided over the conference; the chair at the morning session was taken by Colonel T. U. Wilson, county surveyor of Lanarkshire, and at the afternoon session by Mr. C. S. Sherriff, chairman of the Scottish Accident Prevention Council.

The conference and exhibition were arranged to make the work of the Road Research Organisation better known to Scottish road engineers, and to obtain from them further information on problems and difficulties peculiar to Scotland. In his opening remarks in the morning session, which was devoted to road materials and methods of road construction, the director of road research, Dr. W. H. Glanville, stressed the need for developing sympathetic understanding and co-operation between the practising engineers, who apply the results of research, and the scientific workers in the laboratory: he explained that the new laboratory would begin as a small organisation; but he hoped it would grow as the problems to be attacked were disclosed and as its usefulness was proved; it would not be a small-scale replica of the main laboratories near London, but would have a character of its own, developing to meet the special needs of Scotland. On the 'materials' side it would be equipped to carry out the basic tests and measurements relating to the study of soils and to the use of stone, bituminous materials and concrete; but its initial function would be to provide Scottish road engineers with a centre of information about the activities of the Road Research Organisation.

The three papers at the morning session dealt with soils, concrete and bituminous materials, and were given by the officers in charge of these sections of the work of the Organisation, Mr. D. J. Maclean, Mr. F. N. Sparkes and Dr. A. R. Lee. Mr. Maclean dealt with the physical properties of soil and its behaviour as part of the road structure, notably with the performance of different types of roller for compacting soil, with the settlement of embankments, with improvements in soil stability by the use of cement and other materials, and with studies of the structural failure of roads; he gave special attention to peat as being a soil of particular importance in Scotland. Mr. Sparkes described studies made in the laboratory of the materials used in making concrete—aggregates, sands, and cements—and their proportioning to produce concrete mixtures of the desired strength and workability; he dealt also with the testing of concrete both as laboratory specimens and road slabs, the development of suitable joint filling and sealing compounds for concrete roads, and the study of the efficiency and mode of operation of concrete mixers, vibrating equipment and other forms of constructional plant. Both Mr. Maclean and Mr. Sparkes dealt with the Organisation's laboratory and field researches bearing on the problem of the 'design' of road pavements, that is, the determination of the minimum thickness of pavement required on a soil of known bearing-power to carry a given volume and weight of traffic.

As a problem of particular application to Scotland, Dr. Lee dealt with the carrying out of satisfactory surface-dressing work in inclement weather, describing the laboratory work on the adhesion of bituminous binders to roadstones in the presence of water, and the field studies on the determination of the correct rates of application of the binder and on the improvement of binder adhesion by the treatment of the stone. Other investigations dealt with more briefly were concerned with the study of binder oxidation and with the determination of the combination of the constituents—aggregate, sand, filler and binder—in a bituminous surfacing mixture to make the best use of locally occurring materials.

In the discussion, Mr. Burnett, the Ministry of Transport divisional road engineer for Scotland, and Mr. Barry, county surveyor of Ayrshire, laid stress on the importance of studying problems arising in the construction of roads on peat, Mr. Burnett being also interested in the possibility of soil stabilization in the construction of roads in the Highlands. Mr. Robertson, county surveyor of Dumfriesshire, felt that most Scottish problems were the same as for the rest of the country, but desired more information on typical Scottish soils; he supported Dr. Lee in favouring tank spraying of the binder in surface dressing, but wanted smaller units with better manœuvrability for Scottish conditions. Mr. Murray, county surveyor of Wigtownshire, pointed out that more local authorities owned their own quarries and plant and used direct labour in Scotland than in England, and he felt that researches on plant would be useful.

In opening the afternoon session, which was devoted to road safety and traffic flow, Sir Patrick Dollan quoted figures showing the serious nature of road accidents and welcomed the present attack upon this problem by the Road Research Organisation. Dr. Glanville explained that whereas the Materials Group had been in being more than fifteen years, road safety research was quite a new venture; much of the subject was complicated and statistical in character, and the great need was for facts instead of opinions. The laboratory at East Kilbride would at first add to the information obtained by the parent laboratory but would deal with problems peculiar to Scotland as they emerged.

The three papers at the afternoon session dealt with road layout-and-traffic problems, with vehicles and skidding, and with statistical aspects; they were given respectively by Dr. R. J. Smeed, deputy director (Road Safety), Mr. G. Grime and Dr. F. Garwood. Dr. Smeed pointed out that a proper understanding of road safety must necessarily involve a detailed study of traffic behaviour in relation to road layout. He described the various forms of traffic counter and vehicle-speed measuring device the Laboratory was developing, and summarized some of the results obtained by parties of observers working in and near London. As a smaller investigation which had already yielded results of practical value, he instanced the work with models on pedestrian crossings; this had shown the superiority of longitudinal alternate black and white stripes 1 ft. in width over various other ways of marking the road surface.

In discussing vehicles, Mr. Grime dealt in detail with the problem of dazzle in night-driving as a major cause of accidents: field investigations had shown that low-mounted pass lamps could illuminate an adequate length of road only if they were tilted upwards in such a way as to cause dazzle to oncoming drivers. As a consequence of a survey conducted by the Laboratory with the help of police authorities, new regulations dealing with the mounting of pass lamps would be introduced by the Ministry of Transport next year. In dealing with skidding, Mr. Grime described the apparatus and method used for making routine road tests for local authorities, and summarized briefly the more fundamental work being carried out on the mechanism of skidding and on the influence of road slipperiness on road accidents.

Dr. Garwood dealt largely with methods proposed for studying the statistics of personal injury accidents to be supplied by the police according to the scheme outlined in the final report of the Ministry of Transport's Road Safety Committee. He appealed to local authorities for their co-operation in obtaining additional statistical material.

In the discussion, Mr. Bruce, city engineer of Glasgow, suggested that parked vehicles were often a contributory cause of accidents. Mr. Whyte, of Stirling Highways Committee, suggested that figures might show that certain types of bus were more accident-prone than others, due to causes inherent in the design. Dr. Fiddes, of the Department of Forensic Medicine, University of Edinburgh, stressed the importance of the personal factor in accidents, and felt that an inquiry would be useful into the value of various types of propaganda.

At the conclusion of the conference, the members inspected the exhibition of work in progress at the Road Research Laboratory. The impression left by the proceedings was that a useful step had been taken towards an objective which is regarded as a vital one in all branches of industry at the present time, and which was stated by Sir Henry Tizard at the British Association meeting at Brighton as being that of "applying what is already known". It was evident also that the characteristics of soil and climate peculiar to Scotland would provide many interesting problems for the Scottish branch of the Laboratory.

RADIOACTIVE AND STABLE ISOTOPES FOR RESEARCH PURPOSES

AFTER the announcement of the starting up in August 1947 of the British low-energy pile, known as G.L.E.E.P., at the Atomic Energy Research Establishment at Harwell, numerous inquiries were received regarding the availability of radioactive isotopes for research purposes. The Ministry of Supply has now issued a statement showing the present position, both with regard to radioactive isotopes already produced at Harwell or now available in Great Britain from American sources, and also with regard to separated stable isotopes and mass-spectrometer facilities at present available for research purposes in Great Britain.

Production of Radioactive Isotopes at Harwell. Radioactive isotopes have now been produced at Harwell for some months in the low-power pile in order to provide for the immediate needs of research workers in science and industry. The average number of samples of radioactive material made in the last few months has been about 120 per month, of which about two-thirds have been for users outside the Establishment, and the production from the small pile is now nearing its maximum.

The slow neutron flux available in the pile for isotope production is of the order of 10^{10} neutrons/sq. cm./sec., and the pile is run continuously at high power for about sixty hours each week. Standard irradiations are made in the core of the pile, where there is a mixture of fast and slow neutrons. The thermal column is also available and provides nearly pure thermal-neutron fluxes of about 10^7–10^8 neutrons/sq. cm./sec., with some gamma background. The specific activities of isotopes produced by (n, γ) reactions can be calculated approximately from the published tables of activation cross-sections[1]. At the present early stage, it is not possible, however, to guarantee the exact specific activity of any individual sample irradiated, since the neutron flux varies considerably according to the position of the sample in the pile during irradiation.

As an example of the specific activities attained, samples of sodium-24, potassium-42 and bromine-82 have been prepared having specific activities of the order of 2·0, 0·3 and 2·5 mc. per gm. of element. These isotopes have up to the present been the most useful to biological workers in Great Britain, particularly since the short half-lives preclude their import from the United States. A much greater variety of elements has been irradiated for physicists and chemists. Isotopes resulting from (n, p) reactions or from β-decay chains, particularly phosphorus-32 and iodine-131, are also prepared in small quantities, either carrier-free or with high specific activities. At present, however, the demand for these separated isotopes far exceeds the supply.

In order to make the best use of the limited slow-neutron fluxes in this low-power pile, users are encouraged to have preliminary discussions of any unusual problem with the Isotope Information Office at Harwell. All allocations of radioactive isotopes are made subject to the approval of the Isotope Allocation Committee (see below).

For irradiations of any material in the low-power pile, a standard handling charge of £3 3*s*. (or £2 2*s*. for repeat orders) is made for each four-week period or part thereof, and there is no charge based upon activity. For separated isotopes, which are nearly carrier-free, it has been found convenient to fix charges equivalent to those made for the same material by the United States Atomic Energy Commission, except that when the quantity available is limited some reduction of the handling charge is made.

When the larger pile at Harwell begins to operate at full power, ten to twenty times higher neutron fluxes will be available, and the conditions in the pile will be such that the specifications of the materials available will be very similar to those published by the U.S. Atomic Energy Commission[2]. It is expected that the quantities of isotopes produced will be sufficient to meet all expected demands for scientific, industrial and medical purposes in Great Britain.

Some radioactive isotopes, particularly when they are short-lived, will be distributed directly from the Establishment at Harwell. Where, however, production involves chemical extraction or where subsequent processing or synthetic work is necessary, the processing, packaging and distribution will ultimately be undertaken by the Ministry of Supply Radiochemical Centre at Amersham; a statement on the services to be provided by the Radiochemical Centre in the distribution of both natural and artificial radioactive substances will be issued in the near future.

Facilities for Neutron Irradiations at Harwell. It is possible to irradiate small quantities of material in the pile, including some biological materials. Particulars of the neutron flux available and other relevant details are given above. These irradiations are usually carried out along with the preparation of isotopes.

Availability of Radioactive Isotopes from the United States and Canada. The U.S. Atomic Energy Commission announced in September 1947 that radioactive isotopes were being made available for medical, biological and scientific research purposes in foreign countries. Arrangements were accordingly made by the British Government under which the Ministry of Supply is able to purchase certain isotopes to supplement those being produced at Harwell. Small quantities may also be purchased from the Canadian National Research Council.

In order to comply with Treasury requirements on expenditure of dollars and with the arrangements made with the American authorities, requests for these isotopes must be sponsored by an appropriate authority: for medical and biological research, and for therapeutic uses, the Medical Research Council (inquiries to the Secretary, Medical Research Council, 38 Old Queen Street, S.W.1); for agricultural and veterinary research purposes, the Agricultural Research Council (inquiries to Mr. W. G. Alexander, 6a Dean's Yard, Westminster, S.W.1); for research in other branches of science, and for industrial research, the Department of Scientific and Industrial Research (inquiries to the Secretary of the Department, 24 Rutland Gate, S.W.7). A number of consignments of isotopes have been received under this arrangement, mostly for medical research purposes.

Availability of Stable Isotopes. Following discussions last year between the Department of Scientific and Industrial Research, the Medical and Agricultural Research Councils and the Ministry of Supply, the Ministry purchased from the Eastman Kodak Co. at Rochester, N.Y., a quantity of the N^{15} isotope of nitrogen at 200 dollars per gram of N^{15} at a concentration of 30 per cent in the ammonium radical of ammonium nitrate. Part of the material obtained has already been allocated to the Medical Research Council and also to one or two investigators sponsored by the Department of Scientific and Industrial Research. The remaining material, amounting to several grams of N^{15}, is at present held at the Atomic Energy Research Establishment and can be made available for research workers whose research is sponsored by the appropriate body referred to above. A few grams of enriched C^{13}, in concentration ranging up to 50 per cent, has also been purchased from the United States for medical research purposes in Great Britain.

With regard to production in Britain, it is understood that commercial production of enriched N^{15} is being undertaken by Genatosan, Ltd., at Loughborough, and that the firm will offer this isotope for sale generally. A plant for the production of enriched C^{13} by the use of the distillation-exchange process using liquified carbon monoxide is nearing completion at Harwell. This is expected to meet British requirements for some time to come. In addition, a thermal diffusion plant capable of enriching the O^{18} isotope of oxygen by a factor of 100 is nearing completion, and it is expected that quantities of this material will become available at Harwell in about three months time.

Electromagnetic separation equipment is also being built at Harwell for the production of small quantities of many other separated isotopes for research purposes. Isotopes of the very high purity attained are essential for many research purposes in nuclear physics.

Mass Spectrometer Facilities. One of the difficulties attending the use of stable isotopes at present in Great Britain is the lack of facilities for assay; and until the position is relieved by the construction of further mass spectrometers, full use should be made of the instruments which are available. The Medical Research Council has two instruments operating at the National Institute for Medical Research, Hampstead, and is prepared to do assay work and to advise in the preparation of samples from biological material. The Atomic Energy Research Establishment is also prepared to do a limited amount of assay work on gas samples prepared in standard 'break-seal' tubes obtainable from the Establishment.

Allocation of Isotopes among the various Users. In order to allocate the available isotopes among the users in various fields of research, an Isotope Allocation Committee has been set up, under the chairmanship of Sir John Cockcroft. The membership of the committee includes representatives of the Medical Research Council, the Agricultural Research Council and the Department of Scientific and Industrial Research, the latter representing universities and industrial interests. This Committee will decide questions of allocation of isotopes in short supply, taking into account the urgency of the investigation in question and the facilities available for its conduct. It will be necessary for this Committee to be satisfied that adequate precautions are being taken in the handling and disposal of radioactive materials.

This Committee will also decide on priorities and allocation of stable isotopes produced at Harwell while these are in short supply.

Fuller information about facilities at present available can be obtained from the Isotope Information Office, Atomic Energy Research Establishment, Harwell, Nr. Didcot, Berkshire.

UNESCO AND A WORLD SOCIETY

THE United Nations Educational, Scientific and Cultural Organisation was created on November 16, 1945, and now, nearly three years later, comes a Ministry of Education pamphlet reporting on its progress*. In its constitution the purpose of the Organisation was declared to be "advancing through the educational and scientific and cultural relations of the peoples of the world the objective of peace and of the common welfare of mankind for which the United Nations was established and which its charter proclaims".

Since its inception, the Organisation has been attacked because it has failed to stir the imagination of the people and, in consequence, remained quite unknown to the vast majority. These are criticisms which the Unesco secretariat admits, but insists that they were inevitable during the preparatory stages of the Organisation. For three years the policy has been to build a solid foundation, and the officials have deliberately eschewed the kind of publicity which would make the Organisation appear to be a patent medicine or a political stunt. Now they believe the preparatory work has been done and the time has come to arouse public interest in an agreed programme. The demand for information is rapidly increasing, and the present pamphlet is the beginnings of a campaign in which, by means of literature and speakers, it is hoped to make Unesco a living force and a household name in Britain.

With this pamphlet at least the campaign for popular sympathy and collaboration has made a good start. The origins of Unesco are placed in historical perspective, with the theme emerging that "we are now in process of becoming members of a world society conscious of the singleness of man and of the universe". Nor does this high-sounding phrase mean that the Organisation is dominated by any spirit of complacency. It is frankly recognized that it may not achieve its declared purpose, but it will still have made an effective contribution to the growth of a world society as the successor to the International Institute for Intellectual Co-operation and, more immediately, the Conference of Allied Ministers of Education.

---

* Ministry of Education Pamphlet No. 12: UNESCO and a World Society. Pp. 46. (London: H.M. Stationery Office, 1948.) 1*s.* net.

"UNESCO and a World Society" shows how the Organisation is constituted, the function of its subdivisions and the range of its activities. All this is clearly set out, as is also the controversy between those who believed that the Organisation should be limited and concentrated for the intellectual few, and those who declared that to help the minority is not the way to save peace and that the Organisation is not for the pedants but for the people. The design of the Organisation shows how these differing opinions have been fairly reconciled.

Unesco has also been criticized for arranging meetings between men of science to discuss 'obscure' topics on the grounds that the sole purpose of the Organisation is to contribute to peace and security; the critics assert that the Organisation should undertake nothing that cannot be demonstrated on the blackboard to contribute directly to peace. Its position is defended in "the belief that everything contributing effectively to human sympathy through intellectual and spiritual forces is U.N.E.S.C.O.'s business". This being the case, one is tempted to ask why the Organisation has not concerned itself with those sports organisations which have already done so much to bring people of different countries together. Through the Anglo-Netherlands Sports Association, for example, contests of all kinds take place throughout the year between representatives of towns like Sheffield and Nijmegen, Hull and Rotterdam, and Rotherham and Amersfoort. During the interchanges much is done, both officially and unofficially, to give the guests a real impression of the educational, industrial, social, economic and civic life of the town they are visiting. Here is a popular educational movement of peoples which is directly contributing to understanding and which Unesco might develop for its own sake. More interest, too, might be shown in the rapidly developing schemes for the exchange of employees between industrial organisations like the members of the British Iron and Steel Federation and similar industries overseas.

The rest of the pamphlet contains details of the various committees, of work already accomplished by the Organisation and a summary of its immediate programme for Britain. It is a record of increasing activity which needs to be more widely known, and shows that the present publicity campaign will not have begun too early. T. H. HAWKINS

ANNUAL EXHIBITION OF THE ROYAL PHOTOGRAPHIC SOCIETY

THE ninety-third Annual Exhibition of the Royal Photographic Society is again being held in two parts. The second part, which contains the scientific exhibits, opened on October 9 at the Society's House, 16 Prince's Gate, S.W.7, and closed on October 30. The whole exhibition will be shown at the Museums and Art Gallery, New Walk, Leicester, during the period November 6–December 5.

The section on Nature photography again contains many high-speed flash photographs, taken both by day and by night. The value of the method in studying fast movements is well shown by photographs of birds in flight and of the tongue action of toads and chameleons. It can also result in pictures displaying surprisingly beautiful designs. There is a photograph, of a robin alighting on a twig, in which the individual wing feathers are spread fanwise in a manner that could not be seen in any other way. (This photograph, with many others from the Exhibition, is reproduced in "The Year's Photography", the September issue of the *Photographic Journal*.) Of special interest are the several instructive series showing the life-histories of various creatures and plants. These are all well annotated; but the descriptions of the life and habits of the Natal *Peripatus* and of the one-day life of the stinkhorn deserve special mention. It is remarkable how much the presence of a caption, even on an individual picture, increases the interest. There is a picture of a young grey seal among many other equally superb pictures which remains in the writer's memory simply because it is the one with a short descriptive caption.

Many of the scientific photographs are liberally provided with descriptive matter, but there are woeful exceptions. Among these are a pair of excellent photomicrographs of the living spermatozoa of a mouse, one taken with phase contrast and the other by ultra-violet light. Others in the same series show the chromosomes in bean-root cells at different stages in mitosis. These are presumably phase-contrast pictures; but it is not clear in the catalogue, and only the catalogue numbers appear on the exhibits. Another pair of pictures illustrates normal and pathological nerve cells (according to the catalogue), but there is no indication of which is which. Information is also entirely lacking in several pictures labelled "Molecular Design". The writer presumes that these were intended for the pictorial part of the Exhibition—they have no scientific implication as shown.

There is an excellent series comparing results obtained with different kinds of microscope—normal optical, phase-contrast, interference and electron. Another exhibit describes a method of recording the colour aberrations of high-power objectives. A straight-line object illuminated by mercury–cadmium light produces an elongated line spectrum on the photographic plate by means of a grating and prism placed behind the eyepiece. The line object is tilted at a small angle to the normal object plane, so that the position of sharp focus of the spectrum lines of different wave-length varies according to the chromatic aberrations of the system.

Two exhibits illustrate a new method of micro-radiography applied to the investigation of complex alloyed steels. Variations in composition give rise to a fine banded structure, and the identification of the elements responsible is possible by selection of the exposing radiation. Another series, illustrating a technique for resolution testing in autoradiography, demonstrates the possibilities of the autoradiography of plant or animal tissue containing radioactive tracers. Pinhole radiographs of the internal surface of the copper anode of a magnetron enables the distribution, direction and speed of the bombarding electrons, about which little is known in detail, to be determined (see *Nature*, **161**, 244; Feb. 14, 1948).

Nuclear plate photographs illustrate the natural disintegration of radium and radiothorium, a meson track 400 μ long and the effects of selective development on nuclear tracks. Lowering the *p*H of the developer reduces the background relative to the tracks, and addition of bromide restrains the development of alpha tracks before affecting fission tracks.

Among the exhibits deserving special mention is one of lightning flashes taken during a thunderstorm. Owing to the Clayden effect, a flash occurring at the beginning of the exposure appears as a black line on a grey background, while one occurring at the end of the exposure is white. Some high-speed oscillograms demonstrate that it is now possible to record photographically traces made at a writing speed no less than four per cent of the speed of light. There are also some fine cloud studies and a number of large-scale photographs of geological formations taken from the air.

Some of the exhibits are also reproduced as lantern slides, which provide an interesting comparison with the prints. Unfortunately, they are on different floors. The lantern slides also include some beautiful colour transparencies of crystals in polarized light and of photo-elastic stress patterns of loaded beams and other structures.

The medical photographs are not numerous, which is perhaps just as well for the visitor's peace of mind in view of the extreme degree of clarity achieved in the reproduction of detail.

PHYSICAL CHEMISTRY IN PHARMACY

At the British Pharmaceutical Conference held at Brighton in August, the chairman, Dr. N. Evers, gave an address entitled "The Importance of Physical Chemistry in Pharmacy". He claimed that the importance of this aspect of pharmacy has not been sufficiently appreciated in the past and that the pharmacist requires a wide knowledge of physical and chemical properties of materials. Dr. Evers said the pharmaceutical industry is probably concerned with a wider range of materials than any other, even including the food industry; and that the most important asset which the pharmacist possesses as a result of his training and experience is his familiarity with the properties of materials and his knowledge of their behaviour over a range of different circumstances.

In recent years an ever-widening range of new materials has been offered for the use of the pharmacist by the synthetic chemist; substances which, if used with knowledge and skill, can be made to produce almost any desired properties in the product. In order to make the most effective use of these substances, the pharmacist requires a knowledge of the relevant physical chemistry. It should not be necessary to rely on the manufacturer of such products for suggesting suitable formulæ, because only the user is in a position to know exactly what he requires of his product. It is all the more desirable, therefore, that he should possess the knowledge of physical chemistry which will enable him to produce new preparations by the use of such substances, either for the presentation of new drugs or for new methods of presenting old ones.

Applications of Physical Chemistry

Without introducing examples which are recondite or unusual, any attempt to make a list of physico-chemical phenomena which are encountered by the pharmacist could not fail to include the following items:

Solubility
Ionization
Hydrogen ion concentration
Buffer action
Mass action and reaction velocity
Osmotic pressure
Dialysis
Surface tension
Emulsification
Vapour pressure
Diffusion
Colloids
Adsorption
Ion exchange
Chromatography
Rheology
Viscosity
Thixotropy
Properties of gels and mucilages
Properties of suspensions
Aerosols
Melting and solidification
Surface properties of powders
Electrolysis
Electrophoresis
Radioactivity
Photochemistry

This list does not include the applications of physical chemistry in analytical chemistry, but only phenomena which may be encountered in pharmaceutics.

Large-scale manufacturing pharmacy employs many physico-chemical processes such as evaporation, distillation and drying. The design of plant for such processes involves problems which can safely be left to the chemical engineer; but the pharmacist who uses the products must have a sufficient knowledge of the underlying principles of the processes used to enable him to make a choice of the most suitable method from the point of view of both the effect on the product and of cost. For example, in a new process of drying, such as freeze-drying, there may be no previous experience to guide him, and each problem requires its own solution to be worked out from physico-chemical considerations.

The use of adsorbents in the pharmaceutical industry seems to provide endless problems for research. The purification of active principles by adsorption is not a process which has been much developed. It was used in the carbon adsorption process for penicillin, where incidentally it was found that comparatively few types of carbon were really effective adsorbents. Carbon has been used for the adsorption of pyrogens and 'Permutit' for the removal of traces of adrenalin from cortical extracts. Possibly the new base-exchange resins may have some uses in this type of work. They have been used, for example, for the conversion of calcium penicillin to sodium penicillin. Chromatographic separation is not particularly suitable for large-scale work, and probably has its chief uses in the research laboratory and in the purification of highly active substances which are only produced in small quantities.

The sterile filtration of injections bristles with physico-chemical problems mainly connected with the adsorption of active principles by the filtering medium. Even sintered glass is not entirely guiltless in this respect, and there are instances where no method of sterile filtration can be used without loss of potency. There seems no doubt that in some cases the filtering medium exerts a chromatographic effect, and that an initial adsorption may occur which is afterwards washed out.

Rheology

The science of rheology is defined by its chief exponent, Dr. G. W. Scott Blair, as concerned with the "deformation and flow of matter". The two lectures given by Dr. Scott Blair recently to the Pharmaceutical Society gave an indication of the scope of rheology and its importance in pharmacy. It is concerned with the properties of solids and liquids such as viscosity, surface tension, thixotropy, elasticity, hardness or softness, and those vague attributes which we know as 'consistency', 'firmness', 'springiness', 'toughness', 'tackiness', 'body' and other such terms. Many of these properties are not measurable in a quantitative manner, and the human thumb is the most valuable piece of apparatus available for assessing them. The formulation of a product of the desired rheological properties is therefore largely a matter of experience. Nevertheless, these vague rheological properties are produced by a combination of well-known physical properties, and a man with a knowledge of the physical chemistry involved is definitely at an advantage.

Physical chemistry is not easy to make attractive. It is not so teachable as organic chemistry. It requires a knowledge of mathematics, which is repugnant to many minds, or, because of a lack of early training in mathematics, the student cannot appreciate what he is taught. Is the lack of interest in physical chemistry due to the fact that pharmaceutical students do not appreciate its importance in their work ? Are the courses often merely general courses in the subject, in which no attempt is made to adapt them for pharmaceutical students or to bring home the applications of what they are taught to the practice of pharmacy ? Presumably the text-books used are well-known general text-books on the subject, in which pharmaceutical applications are not considered. Surely what is needed is for some genius to arise who will produce a classical text-book of physical chemistry for pharmaceutical students. No student should be taught applied physical chemistry before he learns the fundamentals of the subject, but physical chemistry should be taught to students of pharmacy in the same way as organic chemistry is taught, with a bias towards medicinal compounds.

ARTIFICIAL HUMAN INSEMINATION*

THIS is a disappointing document. The Commission was asked "to consider the practice of human artificial insemination with special reference to its theological, moral, social, psychological and legal implications". But the Archbishop in his preface states that it is not to be taken as a "Church document", though he does not explain what exactly such a document is.

The two sections on the psychological and sociological aspects of the problem are admittedly based upon surmise, for there is no evidence on the subject available either in Great Britain or the United States, and for this reason it might have been well to omit them altogether ; as it is, very little weight can be attached to them.

The real importance of the report lies in two sections : one on the legal aspects, and the other on the theological principles. Both are able and clear, and obviously much thought has been given to them. It is, however, surprising that the religious statement comes at the end. One would have expected it at the beginning, where it should have constituted the major part of the report. For it is in this section that the Christian will look for an authoritative statement and for guidance, and it is here that a Committee appointed by the Archbishop of Canterbury is best qualified to speak. It will no doubt be accepted as the Church's view on the subject for many years to come, and for this reason alone could well have been expanded. Here the question arises : Why does the Archbishop state that it is not to be considered as a "Church document" ? Would it not have been better if this section of the report, at any rate, had been drafted in such a way that it could have been taken as such ? If there had been any chance of the Church as a whole not accepting it, or of its altering its views, then it would certainly have been better for the report not to have made the definite recommendation that steps should be taken "to frame legislation to make the practice [of artificial insemination—donor] a criminal offence" but to have withheld judgment on this point for a little longer. It does not seem possible to have it both ways, for when a committee appointed by the Archbishop advises that a certain practice be made a criminal offence, then such a recommendation, to carry weight, should bear with it the full authority of the Chair of St. Augustine.

The lawyers have produced much the most vigorous section in the report, condemning artificial insemination from the donor as adultery, and from them comes the first suggestion that it be made a criminal offence. They admit, however, that the questions which the practice raises have not yet come before the English courts, and so far as English law is concerned they are only able to quote a speech of Lord Dunedin in the House of Lords, concerning Russell *v.* Russell, 1924 : "and fecundation *ab extra* is, I doubt not, adultery——". They quote, however, a Canadian case, Orford *v.* Orford, which occurred as far back as 1924, and in which a wife alleged that she had been artificially inseminated without her husband's knowledge ; but they omit to mention that no practitioner either here or in Canada or the United States would countenance such procedure, the consent of both partners being a fundamental requirement.

Since the publication of the report there has, however, been a case in the Supreme Court of New York State which has a direct bearing on the problem. In it the judge, Mr. Justice Greenberg, was asked to declare that a child whose mother had been artificially inseminated with the husband's consent was illegitimate. This he refused to do, saying that it would be "inhuman, inhumane and contrary to the highest concepts of sociology[1]. Further, he declared the child to be legitimate and the husband to be the legal father."

The question of the artificial insemination of unmarried women is raised, but it is very difficult to believe that the Commission had any evidence that it has been practised in Britain, for all responsible opinion is against it. Another point that might in fairness have been stated clearly is that the child of a married woman is presumed to be legitimate unless proved to be otherwise ; a very difficult proof to produce, and the lack of which would make it impossible to enforce any law against donor insemination, when it has been performed with the husband's consent, unless, of course, the medical practitioner who performed the insemination himself gave information, thereby laying himself open, as the lawyers suggest, to a charge of criminal conspiracy, which is indeed unlikely to happen. This again raises the question whether such law would have the backing necessary from the public to make it effective.

The legal section is in strong contrast with the rest of the report, where obvious efforts have been made to keep a balanced and charitable judgment. This is a pity, because unless the practice is made illegal—and it is very doubtful if this will be done—artificial insemination is likely to continue on the very small scale that it has in the past; in which case the law should be amended and added to in order to safeguard the interests of the small number of parents, medical men and children involved, where these are threatened. There would seem, too, to be a parallel here with the law regarding abortion. This is illegal except where the mother's health is endangered. Would it not be possible that artificial insemination—donor might be made illegal, too, except on the same grounds?

---

* A Report of a Commission appointed by His Grace the Archbishop of Canterbury. (S.P.C.K.) 2*s.* 6*d.* net.

The findings of the Commission are that "assisted insemination" between husband and wife may be justified and, with one dissentient, that artificial insemination—husband may also be justified; but that artificial insemination—donor is wrong in principle and contrary to Christian standards. It is further recommended that "early consideration should be given to framing of legislation to make the practice a criminal offence".

It is pleasant to turn to the minority report by Dr. W. R. Matthews, the Dean of St. Paul's, who did not feel that he could sign the report. While everyone may not be in complete agreement with his views, all can admire the spirit which inspires them. He admits that he, like almost every normal person, finds the subject repugnant; but he does not, therefore, think that this necessarily makes it wrong. He says of the Commission: "We should have done better if we had been content to state what we believe to be the proper attitude of Christians to A.I.D. in the present circumstances, while reserving the question of its absolute condemnation in all circumstances to further study"—an opinion which many puzzled people of goodwill are likely to endorse.

THE JOHN INNES HORTICULTURAL INSTITUTION

THE John Innes Horticultural Institution is perhaps best known in the scientific world for its great part in genetical work, under its three successive directors, Bateson, Hall and Darlington. While its contributions to science in the field of cytogenetics have been so outstanding, sight must not be lost of the more directly horticultural research in the applied sphere which has steadily progressed at the Institution and which has resulted in advances of knowledge no whit less important. Throughout, the work has been a model of what applied research should be, the scientific approach to the problems of the practical grower. The work of M. B. Crane on compatibility and incompatibility in fruits illustrates this conception of applied research in a striking manner; not only does it constitute an outstanding advance in scientific knowledge, but also it is the foundation of all modern systems of orchard planning. His "Fertility Rules in Fruit Planning" (Leaflet No. 4 of the new collected edition of the John Innes Leaflets*) is the *vade mecum* of all growers laying out new plantations.

No less important to the horticulturist is the work of W. J. C. Lawrence on the preparation of soil composts for glasshouse plants. The aim throughout the work has been the standardization of materials and methods so that growers anywhere may rely upon reproducible results of proved excellence. It is a further and a large step in the direction of what is, after all, the goal of every grower—complete control over every phase of a plant's growth to the greater benefit of man's nutritional and æsthetic needs. Those who cavil at new scientific ideas as 'interference with Nature' should pause for a moment to consider how every operation the gardener undertakes is 'interfering' with 'natural' processes.

In this collected edition of leaflets, prepared, as the preface states, "in order to put the grower, the gardener, and the seedsman into touch with the latest results of research", a new leaflet on seed production has been added. This is of first importance to the horticulturist because it summarizes information which is difficult to find in print elsewhere. The classification of field and garden crops by degrees of cross-pollination, the methods of isolation by time and distance, and the distinction between the needs of commercial and stock seed are vitally important to all who embark upon the difficult work of seed growing.

The John Innes Institution has done great work for the horticulturist, and when it has settled into its new home at Bayfordbury, with the enormously greater potential facilities it will have, we may look forward to a new series of these practical, yet wholly scientific, leaflets.

R. H. STOUGHTON

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, November 15

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (in the Reynolds Hall, College of Technology, Manchester), at 5.30 p.m.—Prof. L. Rosenfeld: "Conceptions of Force in Physics" (Wilde Memorial Lecture).*

INSTITUTION OF ELECTRICAL ENGINEERS, EDUCATION DISCUSSION CIRCLE (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Discussion on "What Fundamental Principles should be Illustrated in Electrical Engineering Courses, and at what Stage should they be Introduced?" (to be opened by Prof. J. T. MacGregor-Morris).

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 8.15 p.m.—Capt. D. P. Mason: "New Discoveries in British Antarctica".

Tuesday, November 16

UNIVERSITY COLLEGE, LONDON (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. S. J. F. Philpott: "Psychology as a Science", I.* (Second Lecture will be given on Thursday, November 18.)

ROYAL SOCIETY OF ARTS, DOMINIONS AND COLONIES SECTION (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. Basil F. J. Schonland, F.R.S.: "Recent Scientific Developments in South Africa".

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (in the Chemistry Department, Royal College of Science, Imperial Institute Road, London, S.W.7), at 2.30 p.m.—Mr. A. Muir: "Soil Survey and Soil Classification".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Dr. S. F. Birch: "Recent Advances in the Chemistry of Hydrocarbons". (Further Lectures on Tuesdays, November 23, 30 and December 7.)

INSTITUTION OF ELECTRICAL ENGINEERS, MEASUREMENTS SECTION (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Measurement of Telecommunications Efficiency" (to be opened by Mr. W. West).

SOCIETY OF CHEMICAL INDUSTRY, PLASTICS GROUP (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Prof. J. Kendall, F.R.S.: "Leo Hendrik Baekeland and the Development of Phenolic Plastics" (Baekeland Memorial Lecture).

INSTITUTION OF THE RUBBER INDUSTRY (at Caxton Hall, Caxton Street, London, S.W.1), at 7 p.m.—Dr. W. D. Rae: "Dielectric Heating of Rubber".

ROYAL STATISTICAL SOCIETY, TEES-SIDE SUB-GROUP OF THE INDUSTRIAL APPLICATIONS SECTION (at the Cleveland Scientific Institution, Middlesbrough), at 7.15 p.m.—Mr. L. T. Wilkins: "Incentives and the Young Worker". (To be repeated on Wednesday, November 17, at 6.30 p.m., at the Newcastle Chemical Industries Club, 18 Lovain Place, Newcastle-upon-Tyne.)

Wednesday, November 17

INSTITUTE OF FUEL, NORTH-WESTERN SECTION (at Radiant House, Bold Street, Liverpool), at 2.30 p.m.—Mr. S. N. Duguid: "The Fight for Fuel Efficiency". (To be repeated on Wednesday, December 8, at the Engineers' Club, Albert Square, Manchester, at 6.30 p.m.)

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Mr. F. H. Ludlam: "The Physics of Clouds".

ROYAL MICROSCOPICAL SOCIETY (at B.M.A. House, Tavistock Square, London, W.C.1), at 5.30 p.m.—Dr. A. F. W. Hughes: "The R.M.S. Film Library".

SOCIETY FOR VISITING SCIENTISTS (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion on "Scientific Man-Power" (to be opened by Dr. C. P. Snow and Mr. P. H. Brind).

Thursday, November 18

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Special General Meeting to consider the Annual Report of Council; Mr. H. R. Marston: "The Scope and Activities of the Nutrition Laboratories of the Australian Council for Scientific and Industrial Research, Adelaide".

LONDON MATHEMATICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Annual General Meeting; Dr. R. Rado: "Quantitative Covering Theorems".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Prof. E. K. Rideal, F.R.S.: "Selected Topics in Colloids". (Further Lectures on November 25, December 2 and 9.)

UNIVERSITY OF LONDON (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Mr. C. W. Phillips: "The Excavation of the Sutton Hoo Ship Burial".*

BRITISH INSTITUTION OF RADIO ENGINEERS. LONDON SECTION (at the London School of Hygiene, Keppel Street, London, W.C.1), at 6 p.m.—Mr. D. H. Hughes: "V.H.F. Radio Equipment for Mobile Services".

CHEMICAL SOCIETY, SOUTH WALES BRANCH (in University College, Cardiff), at 7 p.m.—Prof. Wilson Baker, F.R.S.: "The Chemistry of Penicillin".

TEXTILE INSTITUTE, BELFAST SECTION (at Queen's University, Belfast), at 7.30 p.m.—Dr. R. H. Sloane: "The Electron Microscope".

UNIVERSITY OF LONDON (at Wye College, Wye, Kent).—Mr. R. L. Wain: "The Chemist and Problems in Plant Protection".*

Friday, November 19

INSTITUTION OF CHEMICAL ENGINEERS (in the English Theatre, the University, Edmund Street, Birmingham), at 4.30 p.m.—Prof. F. H. Garner: "Extractive Distillation".

INSTITUTE OF NAVIGATION (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5 p.m.—Dr. G. N. Harvey: "Magnetic Compass Problems, a Fresh Approach".

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Mr. K. Baumann: "Heat Engines" (Thomas Hawksley Lecture).

ROYAL INSTITUTE OF CHEMISTRY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Prof. J. C. Earl: "Some Experimental Studies in the Chemistry of Nitrogen Compounds" (Streatfeild Memorial Lecture).

SOCIETY OF DYERS AND COLOURISTS, MANCHESTER SECTION (at the Midland Hotel, Manchester), at 6.30 p.m.—Dr. E. Krahenbuhl: "New Principles in the Continuous Dyeing of Wool".

PLASTICS INSTITUTE (at the Engineers' Club, Albert Square, Manchester), at 6.45 p.m.—Mr. A. A. K. Whitehouse: "Polystyrene".

INSTITUTE OF PHYSICS, MANCHESTER AND DISTRICT BRANCH (in the New Physics Theatre, The University, Manchester), at 7 p.m.—Dr. A. B. D. Cassie: "Physics in the Wool Industry".

SOCIETY OF INSTRUMENT TECHNOLOGY, MIDLAND SECTION (at the Arden Hotel, New Street, Birmingham), at 7 p.m.—Mr. Eric E. Hancox: "Thermocouples".

SOCIETY OF GLASS TECHNOLOGY, NORTH-WEST SECTION (at the Gas Showrooms, Radiant House, St. Helens), at 7.15 p.m.—Prof. W. E. S. Turner, F.R.S.: "The Fundamental Basis of Glass Smelting".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. F. E. Simon, F.R.S.: "Power Sources and Power Utilization".

Thursday, November 18—Friday, November 19

SCIENTIFIC INSTRUMENT MANUFACTURERS' ASSOCIATION (at Caxton Hall, Westminster, London, S.W.1).—Symposium on "The Applications of Electronics to Research and Industry".

Saturday, November 20

ROYAL AERONAUTICAL SOCIETY (joint meeting with the HELICOPTER ASSOCIATION, at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 11 a.m.—Discussion on "Helicopters".

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 2.30 p.m.—Dr. E. Ashworth Underwood: "Artists, Anatomists and Anatomical Illustration".*

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

VETERINARY SURGEONS (6), and a FIELD and RESEARCH OFFICER, in the Department of Veterinary Services, Southern Rhodesia—The Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (November 19).

LECTURER (Grade I) IN ELECTRICAL ENGINEERING—The Secretary, The University, Edmund Street, Birmingham 1 (November 20).

MECHANICAL ENGINEERS (3, Senior Principal Scientific Officer Grade) in the Royal Naval Scientific Service, for (*a*) design and development of torpedoes, (*b*) design and development of fire control directors for H.M. ships, (*c*) for charge of the engineering division at H.M. Underwater Detection Establishment, Portland—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2305 (November 25).

PHYSICISTS (Senior Scientific Officer and Scientific Officer Grades) in Ministry of Supply Research and Development establishments in S.E. England—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.365/48A (November 27).

INTERNATIONAL WOOL SECRETARIAT WOOL RESEARCH SCHOLARSHIPS—The Registrar, The University, Manchester 13 (November 30).

HAROLD JOHN COTES FELLOWSHIP IN PROTEIN ENZYMOLOGY—The Registrar, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7 (November 30).

LECTURER IN ZOOLOGY in connexion with teaching to veterinary students in the University of Glasgow and Glasgow Veterinary College—Mr. James Austin, County Buildings, 149 Ingram Street, Glasgow, C.1 (November 30).

AERODYNAMICISTS (Senior Scientific Officer and Scientific Officer grades) for Ministry of Supply posts in London—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.364/48A (November 30).

DIRECTOR OF RESEARCH—The British Gelatine and Glue Research Association, Sardinia House, 52 Lincoln's Inn Fields, London, W.C.2 (November 30).

LECTURESHIP IN VERTEBRATE ANATOMY in the Department of Zoology of University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (November 30).

LECTURER IN THE DEPARTMENT OF ANATOMY of the University of the Witwatersrand, Johannesburg—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (December 15).

READERSHIP IN PHYSIOLOGY at London Hospital Medical College—The Academic Registrar, University of London, Senate House, London, W.C.1 (December 16).

SENIOR LECTURER IN BIOCHEMISTRY in the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (December 31).

TUCKER-PRICE SCIENTIFIC RESEARCH FELLOWSHIP for research in mathematics, science or an allied subject—The Secretary, Girton College, Cambridge (January 15).

HEADSHIP OF THE COLLEGE—The Clerk, National College of Rubbe Technology, Northern Polytechnic, Holloway Road, London, N.7.

TECHNICAL ASSISTANT (Development) in the Directorate of Ordnance Factories (Filling), under the Ministry of Supply—The Technica and Scientific Register (K), York House, Kingsway, London, W.C.2 quoting F.911/48A.

SENIOR EXPERIMENTAL OFFICER (Chemist, male) in the Plan and Animal Products Department for laboratory work in connexio with investigations of Empire raw materials of plant and anima origin—The Establishment Officer, Imperial Institute, South Kensington, London, S.W.7.

CHEMISTS (2, male) for works in a N.E. Scottish town, preferably with some experience in electro-chemical and physical chemistry—The Ministry of Labour and National Service (K), York House, Kingsway, London, W.C.2, quoting F.812/48A.

ORGANIC CHEMIST to take charge of a small group for fundamental work on the organic chemistry of cellulose—The Acting Secretary British Rayon Research Association, 58 Whitworth Street, Manchester 1.

ASSISTANT (with Inter.B.Sc. or equivalent) FOR ANALYTICA LABORATORY—The Assistant Secretary, British Coal Utilizatio Research Association, Randall Road, Leatherhead.

TECHNICIAN (Grade II) IN THE DEPARTMENT OF ANATOMY—Th Secretary, University College, Gower Street, London, W.C.1, quotin Anatomy/2.

GEOLOGIST IN THE DEPARTMENT OF WATER DEVELOPMENT, Tanganyika—The Director of Recruitment, Colonial Service, 2 Sanctuar Buildings, Great Smith Street, London, S.W.1.

CHEMISTS or ENGINEERS (2) as Experimental Officers in a Ministry of Supply Research and Development Establishment near London for work in connexion with the design and use of electronic and othe instruments required for the investigation of combustion and allie processes—The Technical and Scientific Register (K), York House Kingsway, London, W.C.2, quoting F.903/48A.

CHEMISTS (Senior Scientific Officer, Scientific Officer, Experimenta Officer and Assistant Experimental Officer grades) in Ministry o Supply Research and Development Establishments near Londo (majority of posts are in the physical and analytical fields)—Th Technical and Scientific Register (K), York House, Kingsway, Londo W.C.2, quoting F.900/48A.

CHIEF ANIMAL PHYSIOLOGIST, a BACTERIOLOGICAL CHEMIST, an an EXPERIMENTAL ENGINEER, in the Dairy Research Institute, Masse Agricultural College, Palmerston North, New Zealand—The Hig Commissioner for New Zealand, 415 Strand, London, W.C.2.

FARM MANAGER for the Headquarters Station of the East Afric Agriculture and Forestry Research Organisation, near Nairobi—Th Under-Secretary of State, Colonial Office (Research Department) Sanctuary Buildings, Great Smith Street, London, S.W.1.

SENIOR LECTURER IN CHEMISTRY—The Clerk to the Governors Chelsea Polytechnic, Manresa Road, London, S.W.3.

LECTURER IN CHEMISTRY to Intermediate B.Sc. stage—The Principal, Medway Technical College, Gardiner Street, Gillingham, Kent

ASSISTANT CONTROLLERS (Engineering) (Ref. No. 27323/8A), an ASSISTANT CONTROLLERS (Radio) (Ref. No. 27323/8), in the Department of Telecommunications, Federation of Malaya and Singapore—The Director of Recruitment, Colonial Service, Sanctuary Building Great Smith Street, London, S.W.1.

MATERIAL AND ETHICAL PROGRESS

THE need for restoring the balance between man's material and his spiritual advance has been a recurring theme in scientific discussion, and in the writings of such men as Louis Mumford and K. Mannheim, since the memorable presidential address given by General Smuts at the centenary meeting of the British Association. Papers contributed by Prof. B. Dobrée, and by Dr. D. M. Emmet, Prof. T. W. Manson and S. Hird at two discussion groups on "Science, the Universities and the Modern Crisis" arranged by the Manchester Literary and Philosophical Society in 1944–45 are specific examples of this trend of thought. More recently, Sir Henry Tizard struck the same note as a minor theme in his own presidential address at Brighton, and Lord Samuel's evening discourse on "Science and Philosophy" called imperatively to science to join philosophy and religion in promoting a synthesis which would be adequate to redeem this age from past calamities and rescue it from present dangers.

The approach to this problem of balance or of synthesis has been made from various sides: from that of education, as in the Manchester discussions; of philosophy, as with General Smuts and Lord Samuel; and of religion, as in an important section of the recent report of the Lambeth Conference. It has also been approached from that of human relationships. The importance of such relationships in industry and in the State give special interest to the study of the critical problems in human relationships to-day at the "Present Question Conference" held in Birmingham last year. The addresses and discussions at that Conference have recently been published*. They follow the discussion at an earlier conference of the question "Is the present chaos caused by lack of scientific planning or by failure to recognize the reality of spirit?" It is to be hoped that addresses and discussions at the Conference last August on the problem of leadership in a free society, which are in sequence with those contained in the present pamphlet, will likewise be available at an early date.

In introducing the three lectures, by Dr. J. H. Oldham, Mr. Herbert Read and Mr. G. W. Knight, which, with the subsequent discussions, comprise this pamphlet, the editor maintains that we are concerned less with a problem to be solved than with an idea to be experienced, and that the creative power in the soul of man which in a mechanical age makes it possible for him to become a person is the same principle that in earlier ages has given life and order to society. Dr. Oldham, pointing out that the answer to the question regarding human relations depends on one fundamental belief about the essential nature of man, proceeds to a penetrating analysis of the implications of a free and tolerant society and its maintenance in the face of threatened domination by impersonal forces and central direction by 'social engineers' or planners. In the modern period of history men have come more and more to think of themselves as individuals in a world which it is man's primary business to understand, explore and subordinate to his own purposes. We have now to ask whether this is the only attitude, or even the most important attitude, of man to his world.

---

* Question: a Journal. Vol. 1, No. 1, July 1948. The Critical Problem in Human Relationships Today. By G. Wilson Knight, Herbert Read and Dr. J. H. Oldham. Pp. 87. (London: Hammond, Hammond and Co., Ltd.) 2*s*. 6*d*. net.

Dr. Oldham suggests that this is the point on which some of the most creative minds to-day are working; and he develops the conception of Martin Buber and Nikolai Berdyaev, implicit, perhaps, too in the writings of Jacques Maritain, that there is a fundamental difference in our relations to things and our relations to persons. He acknowledges the influence of the German philosopher Eberhard Grisebach on his thinking, and emphasizes the implications for social and political life of this truth: that man is fundamentally a person and that he finds his satisfaction and happiness, not in solitariness but only in a living relationship with other persons. The critical issue is whether our present preoccupation with things is to be made instrumental to the growth of true community, or whether we are going to be increasingly subject to the domination of things. Both individualism and collectivism are, in fact, a complete denial both of the person and of community.

The task of restoring the balance of human life, which is immensely complicated by the technical developments of our civilization, involves learning or re-learning personal relationships in the family, the neighbourhood and the workshop at the level of our own personal attitude or behaviour. Next, we have to develop ways in which, by the formation of human associations, persons educate and discipline themselves, through relations of mutual responsibility and mutual obligation towards one another. Only in these small groups are full and lasting relations between persons possible. In spite of Dubreuil's experiments, even in industry the implications of the Western Electric investigations associated with the name of Prof. Elton Mayo are not widely appreciated. The human problems of an industrial civilization are, as he pointed out in his last book, the key to industrial relations and to the development by man of the skill to live with his fellows as persons in genuine human relationship.

Beyond this we have to provide opportunities for people to learn in co-operation with others those wider aspects of citizenship which concern our general life. Here alone can we develop the real core of resistance to totalitarianism. The development of a hierarchy of groups—families, towns, counties, regions, trade unions, universities—with healthy and vigorous lives of their own, is the surest way of resisting effectively the encroachments of central authority and thus maintaining a free society. The preservation, not merely of freedom of the human spirit, but also of those other freedoms, of utterance and investigation, upon which that spirit is nourished, ultimately depends upon the existence of such groups. Moreover, they offer, too, an invaluable means of reaching that decision which may have to be made as to which in practice are the vital freedoms to preserve and which must be surrendered to preserv the others. Local associations with a strong, healthy independent life of their own are the only means securing a body of citizens alert to detect an protect those points at which freedom is threatene and who will not be deceived by the casuistry totalitarianism into surrendering those freedoms whic are essential to the growth of the human spirit. Th pattern of Dr. Oldham's thought can be traced i Lord Lindsay's "Religion, Science and Society in th Modern World", as well as in Prof. Elton Mayo's an Dr. K. Mannheim's books.

Mr. Read's paper, on "The Moral Principle i Education", has for its theme that in education w must give priority to all forms of æsthetic activit because in the making of beautiful things the emotio crystallize into what are in effect social patterns, th patterns assumed by human relationships. M Knight gives a fresh interpretation of the positi aspects of Nietzsche. Both offer a profound an more constructive contribution than any of th miscellaneous papers in "Civilisation"[*], a collecti of essays by J. Prévost, L. de Broglie, A. J. Toynbe H. Nicholson, R. Speaght, M. de Corte, Aldo Huxley and others, through which runs the *leit mot* of a dying civilization—a pessimism almost entire unrelieved by any birth-pangs of a new age, or eve the hope of a new civilization.

It is true that here also it is recognized that me need to renew their belief in the eternal values, an that civilization must have spiritual foundation but however searching the criticism of the wea nesses of civilization, it is pervaded by a spirit defeatism rather than by any firm confidence th man will triumph over the new barbarism. T brilliance and confidence that mark the no le searching analysis of Charles Mayer in "L'Homme vaut que par le progrès"[†] are absent. Devastati and disconcerting as is Charles Mayer in some of t criticisms of this age which he puts into the dialog between the Parisian citizen Durand and the phil sopher-scientist Neon, there is unwavering faith the ability of man's spirit to transcend and transfor his material environment. As André Maurois remar in his preface, Mayer's central theme may be su marized: "Il faut cultiver notre esprit".

In upholding the idea of progress, in which many in this generation have lost faith, Mayer rang over a wide field and is often stimulating and su gestive in his comments on such diverse themes freedom, science and morality, feminism, unemplo ment, education, capitalism, private property, medi practice, scientific research and social institutio He writes with a refreshing forthrightness, and th who are moved to contest any of the scientific pr ciples of a progressive materialism or the princip of a progressive conception of the individual and society with which he concludes the first two pa of his book, can scarcely fail to appreciate the lucid and liveliness of his argument. It is a book wh carries a message of hope and, materialist as he

[*] Civilisation. Edited by F. Berge. Chemins du Monde, No (Paris: Éditions de Clermont, 1947.) 100 francs.

[†] L'Homme ne vaut que par le progrès. Par Dr. Charles Ma Pp. 401. (New York: Éditions de la Maison française, Inc., 1945.)

Mayer reaches, but for different reasons, a belief in the same values as those put forward in the Lambeth Conference report. The social order is indeed, as the Encyclical Letter puts it, all the time being made by the thoughts men think, the loyalties they honour and the deeds they do or leave undone. The world is adrift because it is defying the moral law and repudiating that divine authority which is the basis first of justice and then of peace.

Here then is a fresh challenge to seek out at all levels those new forms of social organisation which are necessitated by the power for the better ordering of the world which the new discoveries and technical inventions of our time have given us. The very condition of survival is the transcendence of outworn experiments in the way of living and social institutions. We have to concentrate anew man's moral and spiritual capacities to employ the material instruments as servants of new possibilities for human well-being. Free institutions cannot be safeguarded solely on a secular basis; and democracy demands for its working those qualities of self-restrained discipline such as have flowered in the training provided by Christian fellowship; while, as the Lambeth report wisely reminds us, we must not allow the State to disregard or throw away the experience and goodwill which are found in voluntary social service.

The diverse issues raised in these three publications never obscure the challenge which they offer to fundamental thought regarding the moral and spiritual values on which alone the rebuilding of Europe and our own recovery can be based, and through which we must find the means to avert the menace which Russian communism offers to the human spirit. With hat challenge to thought, Mayer and Oldham at least point out ways in which we can begin to work out new means, alike in industry and in society as a whole, of safeguarding the freedom of the human spirit and establishing the human relationships which will remove the strain and stress handicapping our ffort at even economic recovery. These are issues which touch the scientific man himself very closely, for they form part both of the strategy and the tactics by which men must secure the conditions in which the human spirit can express itself freely and creatively in science and art and human affairs. The area within which that freedom is possible is steadily being narrowed. Independently of the merits or demerits of particular proposals for the nationalization f industry, the passing of increasingly large areas of conomic life under State control has repercussions on human freedom which ought to be weighed before and not after those measures are implemented.

Here, indeed, is a practical issue to which not only men of science but also professional associations, ade unions, the churches, the universities and other roups should address themselves as a matter of urgency. These publications give a valuable lead; ut there is much to be done before we can elaborate ther the strategy or the tactics of freedom and pply them successfully to particular issues of the y. Dr. C. E. Raven, vice-chancellor of the niversity of Cambridge, remarked recently that creative freedom is the governing concept of university life. It is a vital element in the life of any free community. But any such community that hopes to survive to-day must not think of freedom as a passive state in which we can do as much or as little as we like. As the Queen remarked at Cambridge in reference to Dr. Raven's words, freedom is something more—a force, a dynamic organism which enlivens everything it touches. It is a culture of the mind produced and nourished by the processes of education. Not the least responsibility of men of science to-day, individually and collectively, is to join with all those forces which are seeking to safeguard the free society, and to renew the moral and spiritual forces upon which the creative power of Western civilization depends.

DR. ROBERT BROOM: NATURALIST

Special Publication of the Royal Society of South Africa

Robert Broom Commemorative Volume. Edited on behalf of the Society and the Bernard Price Foundation of the University of the Witwatersrand by Alex. L. du Toit. Pp. v+257. (Cape Town: Royal Society of South Africa, 1948.) 22*s*.

The Royal Society of South Africa has honoured Dr. Robert Broom, of the Transvaal Museum, Pretoria, on the occasion of his eightieth birthday, by publishing a volume of papers by many men on subjects to our understanding of which he has so greatly contributed. After a delightful introduction by General Smuts, we are given a short biography and some personal reminiscences by D. A. Roberts; then follow a number of articles dealing with fossil reptiles, the field of study within which so much of Broom's work has lain.

Beginning with accounts of the structure of the mammal-like reptiles of South Africa, designed to elucidate the mode of origin of mammals, Broom passed on to earlier forms, which include their ancestors, and in so doing revolutionized our ideas of phylogeny, and gave the clue to our present classification. This series ends with a most valuable discussion of the climatic setting of the Karroo reptiles by Mr. du Toit.

Then follows a series on the fossil men and man-like apes of Africa, works which owe their existence to the early recognition by Broom of the rightness of Dart's views about the position in the anthropoids of the young skull of *Australopithecus*.

Inspired by this find in a cave in the Transvaal, Broom examined very many caves and by dogged persistence found those marvellous fossils which he has so accurately interpreted as members of a new family of the Hominidæ, giant apes, adapted to life in semi-arid lands, walking erect like men, with man-like teeth, but with an ape's brain. The discovery and description of these animals is beyond all question the most important contribution to our knowledge of the primates, other than man himself, which has been made for a hundred years or more.

But Broom has also made additions of fundamental importance to our understanding of the human races which have in the past inhabited South Africa. Here again he gave the impetus to the active interest in this subject in South African universities, shown by several papers in the commemorative volume, in which the authors, whether they agree or differ, are at one in starting their arguments from Broom's fundamental works.

Broom's first interest was in embryology, and it is appropriate that the volume should include papers in this field.

Broom has always held that taxonomy in the restricted sense of specific discrimination is not only valuable and necessary, but also demands from the man who does it altogether exceptional judgment. Throughout his working life, Broom has described new species—hundreds of them in fact—and it is pleasant to find new species here described.

The volume contains—unusually but most fortunately—a paper by Broom himself in which is described a whole series of small Theriodonts of very great interest.

A bibliography of Broom's published scientific work which ends the volume includes a list of 402 papers, beginning in 1885, when he was nineteen years old, with a paper on the volume of mixed liquids, in the *Proceedings of the Royal Society of Edinburgh*, and continuing until to-day, so that it needs addition.

Broom's life-work is unparalleled by that of any-one now living. In its range, in its mere mass, it recalls the great Victorians, Owen, Huxley and Lankester; and in its quality, in the extent to which modern work in many fields can be traced back to it, and in the verve and vigour which it shows, it is indeed worthy to be compared with that of these great men of the past. D. M. S. WATSON

THE ANATOMY OF CO-OPERATION

Managers, Men and Morale

By Wilfred B. D. Brown and Winifred Raphael. Pp. vii+163. (London: Macdonald and Evans, 1948.) 10*s*. 6*d*. net.

PERHAPS the most outstanding event in the industrial story of Britain in the 1940's is the advancement in the technique of co-operation between master and man—or, between managers and employees, to put it into its modern wording. Admittedly that story has not everywhere been characterized by undisturbed harmony; but as to the extent of the progress achieved, and its soundness in fact, there can be little room for doubt. In the main, the achievement has been in the realm of formal relations between organised parties, that is, procedures for negotiation and continual consultation between representatives: employers' federations and trade unions on an industry basis, or managers and shop stewards at the individual factory level. Yet there has been an advance, too, in the more informal pattern of consultation that is inherent in the everyday contact of manager and supervisor with the men and women under their jurisdiction—an advance measured chiefly in widespread recognition of this factor as an element in executive responsibility. This fact of employee relationships is, many authorities are coming to agree, of greater significance in the conduct of industry than the formalized pattern characterized by a meeting of 'sides' across a table, more often glaring than smiling, and more often interested in their own respective good rather than in the pursuit of a common task.

It is with this subtler yet more essential form of co-operation that the present book is concerned. "Our theme has been that the practice of management should be based on certain fundamental hypotheses concerning the reactions of the human being to his social environment. . . . We have been organising the production of goods and services for two hundred years with ever increasing success if we measure our achievements in terms of production; but with a most noticeable lack of success if we measure in terms of the effect of our organisation on those engaged in the process of production. Indeed, it almost looks as if the degree of co-operation, pride in work and happiness, arising out of the association of human beings in industry, is less to-day than it has ever been. People have more material possessions to-day, but less psychological satisfaction from their association with the results of our organising."

The framework of the book has been erected to provide for a full study of the fundamentals of co-operation at all levels—the board of directors, the senior executives, the specialist managers and staff, the supervisors and the operatives themselves. The authors frankly disclaim any pretence to a 'text-book', and the chapters devoted to each of these manager-levels are in no sense a review of the detailed practices of management. They are, instead, a scrutiny of the means of creating and maintaining a sense of common task; they describe the anatomy of co-operation, not just the skeleton, but the nervous system as well, and their illustrations draw chiefly on the nervous system in action. Witness this momentous paragraph from the introductory chapter: "If we attempt to achieve efficiency in the hope that happiness will follow, we are usually putting the cart before the horse. Nobody can work efficiently while suffering a sense of injustice, grievance or frustration. Good work cannot be turned out under such conditions. It is clear, therefore, that the task of the manager is to achieve efficiency *through* happiness. It is useless to look at the group we command and say to ourselves: 'I have done everything that a man can reasonably be expected to do to make these people happy, and consequently they should be happy. Now I can forget that issue and concentrate on efficiency.' A manager must continually observe his subordinates and courageously face the facts. I they are not happy, it is useless to escape from the responsibility which that fact imposes upon him by assuring himself that they ought to be happy. Hi job is to find out why they are dissatisfied; then to do everything possible to eliminate the causes o their dissatisfaction."

To say that this book will be misunderstood and misinterpreted is to pay a compliment to the far-sighted approach of its authors. One reader ha commented—and many may sympathize with him—on the curtailment of the authority of management that their teaching represents, as though replacin woolliness of discussion for the firmness of decision. But such readers have not grasped the essentia principles of the study or the real implications o what the authors are saying. A little more unkindly one could say that they have overlooked a fairly lucid passage in Chapter 7: "We are not trying t suggest in any way that authority should be shared The final say must rest with the executive, wh bears the ultimate responsibility. But Mary Parker Follett was abundantly right when she talked about 'de-personalizing orders'. An order must be seen to be the 'law of the situation' if it is to be readily accepted. It will create resentment if it appears to be the whim of the manager. The object of discussing a problem with a group is to find out what the situation is, rather than to put upon them the responsibility of making a decision." There is, in fact, quite a possibility that some readers will squirm at the strikingly autocratic tone in which it is suggested (in Chapter 4) that a managing director might introduce functional experts into his firm.

There are a lot of things that could be said about this book—mostly good things !—and there are a lot of points that could very usefully be taken up for examination or emphasis. In the compass of a short review, however, further comment is perhaps best confined to a selection of the more fundamental issues. The chapter on "The Outside Consultant" is an unusual feature in a serious book on management ; this is an excellent chapter, objective and balanced in its appraisal of the part that the expert consultant can play in the advancement of the practice of management. It has a special relevance to immediately contemporary conditions and is a welcome recognition of the value of the soundly established professional consultant in a new domain.

Chapter 7, "Attitudes in Industry", is again a new feature, describing recently developed techniques for assessing public opinion within a factory on matters that reflect the outlook and competence of management and so are pointers to the level of morale. A kind of 'Gallup poll' of an industrial organisation would be a popular description of the process, though the techniques described are of far less importance than the recognition, which they imply, of influence that the impact of management can exert on the human tone of the organisation. In one sense, this chapter points to a method of diagnosis or study of the anatomy of co-operation, and underlines the authors' own conception of the scientific method in industrial relations—"Management," they say elsewhere in the book, "is a problem of human relations. By definition the manager attains his objective through the government of others. His principal task is therefore that of establishing good relations with those others, both his subordinates and his seniors. If management is to be scientific, it must call upon the knowledge and experience of those who are expert in group relations." This is different only in wording from F. W. Taylor's plea that among the factors in the industrial situation which should be made the subject of systematic analytical study are "the motives that influence men"—a thought which puts the notion of scientific management in a setting very different from that habitually attributed to it.

From scientific method to the establishment of principles is in logical sequence, and so it is fitting that the concluding chapter should refer to targets "embodying certain principles of organisation". Regrettably, the authors have allowed themselves to be deluded into reproducing "principles [which] are to be read as a description of what is actually done in one organisation"—a conception that is difficult to square with the customary connotation of 'principle'. But if the title 'target', as used in the chapter heading, is given to these lists they undoubtedly stand as valuable prescriptions for the betterment of management.

If there is any serious criticism of this study, it is its unmitigated 'producer interest' ; its whole content is aimed at the well-being of those whose lot in life casts them in the processes of manufacturing. Admittedly, the book is not meant to be a study of economics ; but there are many points at which certain assumptions have obviously been made as to the purposes of industrial activities and their relative role in the scale of social values. Those assumptions have clearly been made in terms of the prior interests of the producers—of the workers and managers engaged in manufacturing industry. Specific evidence is difficult to cite, the only clear case being the relegation of consumer interests to the fifth place out of six items to which surplus revenue should be devoted (p. 155).

The existence of purchasers is thinly recognized in the first principle set out as a basis on which a worker can identify himself with the purposes of an industrial community (p. 93), though economists (as well as citizens who have lived through the years 1945–48) would argue that only a price mechanism could determine what manufactures are of no value to consumers because they are either 'a fake' or 'useless' or 'gimcrack'. Consumers—who are really just the workers and managers without their overalls—have unaccountable bases of preference !

It is high time that the professional manager and the technologist recall to mind that the primary purpose of the economic system, of all industrial activities, is the provision of the goods and services that the consumer wants. This can very safely be stated as principle No. 1. E. F. L. BRECH

TRAINING THE WORKER

Principles and Practices of Vocational Education

By Prof. Arthur B. Mays. (McGraw-Hill Series in Education.) Pp. viii+303. (New York and London : McGraw-Hill Book Co., Inc., 1948.) 21*s*.

IT is becoming more and more clear to most people connected with British industry that the way out of the present economic crisis will not be by the introduction of new machines. For some time to come industry has to make do with the bulk of its present capital equipment, and, now that the labour force is stretched almost to its maximum, any real increase in production can only come by a change in methods. This will involve considerable modification of the attitudes of many managers and workers, and to-day various agencies are seeking ways whereby time-honoured behaviour patterns can be changed swiftly and efficiently. Among the ways which have been and are being increasingly used to add to overall efficiency is what industry has come to call 'education and training'. Simple as this may sound, it is surprising that, even in 'enlightened' firms, the process of providing a man with specific training to do a job is often regarded as something which hinders rather than helps production. Engineers, of course, have to be trained ; so have chemists. They may even need a four-year preliminary course before their training starts. But the semi-skilled and unskilled workers can pick up their jobs by being put alongside Joe and Tom. In the Services men are given their training before being assigned to a unit ; in industry many men and women have to learn their jobs by picking up all that cannot be concealed from them.

It is therefore refreshing to pick up a book in which a professor of industrial education indicates not only methods of training different grades of workers, but also carefully examines principles upon which vocational education should be based. The more these principles and practices are disseminated, the more quickly will employers and employees realize that 'education and training' can do much to promote the well-being of workers and, concurrently, industrial efficiency.

Much of the book is devoted to education for the more humble jobs, although one section is given over to a discussion on vocational education at the university-level and another to the preparation of teachers. Probably the most important chapter is that in which the author considers the significance of vocational education in democracy and its relation to industrial productivity. Starting with the late Theodore Parker's dictum that "democracy meant not 'I am as good as you are' but 'you are as good as I am' ", Prof. A. B. Mays emphasizes that modern ideals of democracy call for equality of opportunities for all levels, classes and individuals. "Men to-day require not only that their preachers and lawyers be given opportunity for proper training but that their cooks and chauffeurs also find such opportunities. Not only the engineer, the doctor and the architect but the factory workers, the nurse, and the carpenter must be given a fair chance for vocational education." Nor does the factory worker mean just the skilled fitter, turner or other craftsman. Under the handicraft system of the pre-industrial revolution era these men were mainly responsible for production. To-day, they are mainly concerned with the maintenance of equipment, and most productive processes are performed by unskilled and semi-skilled workers. In industrial training programmes all grades of workers should be included, and Mays makes suggestions for each grade which are similar to those already in practice in a small number of firms in Britain.

It is significant that Mays advocates drastic changes in existing attitudes to the selection, training and status of foremen, and suggests that, if the teaching function of the factory foreman were to become more widely recognized, many of the problems of providing adequate training for unskilled and semi-skilled workers would solve themselves. Much of the chapters on organisation and administration would not be appropriate to British education or industry, but even here Mays' principles are sound, and reinforce the opinion that this is an important and, for British readers, a well-timed book.

T. H. HAWKINS

A NEW THEORY OF LEAF FORMATION

La théorie des hélices foliaires multiples

Fondements d'une théorie phyllotaxique nouvelle. Par Prof. Lucien Plantefol. Pp. 154. (Paris: Masson et Cie., 1948.) 400 francs.

IN this book, which has appeared in parts in recent numbers of the *Annales des sciences naturelles botanique*, the author proposes a new theory of leaf formation, after rejecting as erroneous nearly all previous work. He considers that the positions in which leaves arise depend on a number of generating centres (*centres génératrices*) in the stem apex above them, which form leaves successively along a number of foliar helices winding in *one* direction around the apex or axis. But since these generating centres might get out of time one with another, he also postulates an organising centre (*organisateur*) in the apex to control them. Thus the organising centre is like a conductor, and the generating centres are the players which follow its beat. All these must be within the stem apex, which may be only 150 μ across, or even less.

But what are these foliar helices along which the generating centres act? It is well known that in sections of spiral buds, and less easily on some mature organs, there can be seen two sets of leaf spirals or helices, the parastichies, winding in opposite directions, and that the numbers of these two sets are commonly successive numbers of the Fibonacci series 1, 2, 3, 5, 8, etc. The helices which the author intends are some of these; but which they are and on what principle he selects them is a more difficult question. For he selects only those winding in one direction, and claims that they are of varying numbers in monocotyledons, but usually only two in dicotyledons The only grounds for choosing two in dicotyledons seem to the reviewer to be that the number two occurs in both of the lowest and commonest Fibonacci systems, those with parastichies $1 + 2$ and $2 + 3$ as well as in the decussate system $2 + 2$, and that higher Fibonacci systems are reached by passing through the lowest Fibonacci systems in development.

The theory has something in common with that of Church (1904), whom the author does not mention For Church supposed that the apex forms leaves at the *intersections* of spiral paths, forming continuations into it of the two observed sets of opposite parastichies. He thus did not need to postulate any centra organising centre to regularize matters during constant phyllotaxis, since the uniform growth of the apex would suffice for that. For this reason and also because it is based on *all* the parastichies observed Church's theory seems much preferable for those who favour any theory of this kind at all.

Although the author seeks to account for the sequences and positions in which leaves are formed at the apex, he offers no evidence of what those positions actually are, his whole book containing n illustration of an apex or bud section. Instead h tries to infer from observations on mature organs i what positions the leaves must have been formed But such inferences may be quite wrong, and in pa ticular in certain lilies which the author discusses he clearly does not know what actually are those positions of leaf formation which he seeks to explain He also seems to think that all previous workers have supposed that there was some causal significance in the genetic spiral, which is the spiral drawn throug the leaves in their order of development. But th was not the opinion of Church, nor of those workers who, following Hofmeister, believed that th positions in which leaves arise are somehow determined by the existing leaves just below them. Th evidence in favour of this last opinion is scarcely di cussed. With one point the reviewer agrees: that th divergence angles between the centres of successive leaves in spiral phyllotaxis are not simple fractions 360°. One may confidently expect that if the autho who has won distinction in plant physiology, wi study shoot apices rather than mature organs, h will contribute something of 'greater value' to th theory of leaf formation.

MAGNETISM

SECTION A (Mathematics and Physics) of the British Association conducted a symposium on magnetism at Brighton on September 13, with Sir Lawrence Bragg, president of the Section, presiding over the meeting. Three papers were presented; the first two dealt with materials and the last with a problem in metal physics. The title of the first, by D. A. Oliver, was "Recent Advances in Anisotropic Permanent Magnet Alloys"; that of the second, by N. F. Astbury, was "Anisotropic Silicon Iron"; while the concluding paper, by D. Shoenberg, was entitled "Magnetic Properties of Superconductors". A discussion followed the first two papers and the last one.

Mr. Oliver (William Jessop and Sons, Ltd.) recalled the discovery in 1938 of the effect of inducing anisotropic permanent magnet properties into a cube of 'Alnico' by cooling from 1,200° C. in a strong magnetic field[1]. The subsequent developments by Dutch[2,3] and British[4] workers gave rise to the 'Ticonal' and 'Alcomax' series of alloys which contain more than twenty per cent of cobalt. The successive advances were outlined and special mention was made of the work of Tetley, Edwards and Hoselitz and of the staff of the Philips research laboratories at Eindhoven. Axial and planar[5] anisotropy were distinguished; for the usual, or axial, type of anisotropy it was noted that $(BH)_{\max}$ products of 5 millions (gauss, oersted) are now approached commercially (and occasionally exceeded in the laboratory) when the properties are measured in the preferred direction. This energy value was compared with 1·6 millions for the older (isotropic) 'Alnico'[6]. Typical magnetic constants for 'Alcomax II' are remanence (B_r) 12,500 gauss, coercive force (H_c) 550 oersted, and $(BH)_{\max}$ $4 \cdot 3 \times 10^6$. (The maximum stored magnetic energy in ergs per c.c. is equal to $(BH)_{\max}/8\pi$.) Investigations have recently been conducted along the lines of eliminating chemical impurities, and certain improvements have resulted. The latest research by the Permanent Magnet Association, in collaboration with the British Electrical and Allied Industries Research Association, has shown that niobium (columbium) additions are advantageous for increasing coercivity[7]. With intensive development by the Permanent Magnet Association a new experimental alloy has resulted having tentative constants as follows: (B_r) 11,200 gauss, (H_c) 750 oersted, $(BH)_{\max}$ 4·3 millions. This new material may prove especially advantageous when space considerations limit, in a given piece of equipment, the maximum permissible length of magnet part. Mention was also made of the recent (unpublished) researches by Dr. A. J. Bradley on the iron–nickel–aluminium system. These are throwing much light on the actual structures associated with optimum magnetic properties. The earlier mechanism put forward by Bradley and Taylor[8] in 1938 has been confirmed and extended. Two body-centred cubic phases are the principal ones; the iron-rich being disordered, the nickel–aluminium-rich being ordered after prolonged annealing at 850° C.

Alloys in an optimum magnetic condition show little definition under the microscope when polished and etched (Fig. 1). However, following prolonged annealing at 850° C. for sixteen days and after careful polishing and etching, a clear structure is visible at a high magnification (× 2,000, Fig. 2). Furthermore, evidence has been obtained for cubic mozaic blocks having an edge length of $2 \cdot 5 \times 10^{-5}$ cm. or simple multiples of this dimension. Micro-segregation is present in so far as the nickel–aluminium-rich phase concentrates near the centre of each mozaic block, while the iron-rich phase is found on the exterior. These blocks are subject to magnetostriction biasing effects when the alloy is heat-treated by controlled cooling in a strong magnetic field, and final atomic rearrangements during tempering may be expected to occur in their vicinity. Single domain characteristics may be ascribed to each elementary mozaic block, and the coercivity effects can largely be explained on the lines of the recent theory put forward by Stoner and Wohlfartl.[9]. It is, however, important to recall that the segregation processes are incomplete when the best permanent magnet properties have been established. Then the predominantly

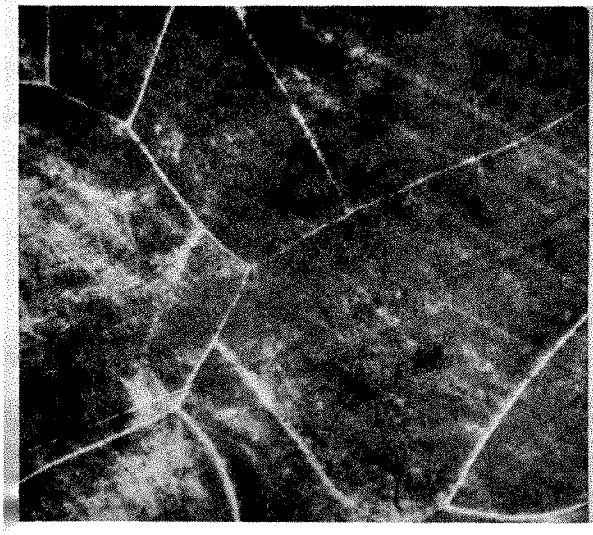

Fig. 1. Typical photomicrograph (× 50) of Fe_2NiAl in optimum magnetic condition. Note poor details after polishing and etching; no improvement with increased magnification. (After Bradley)

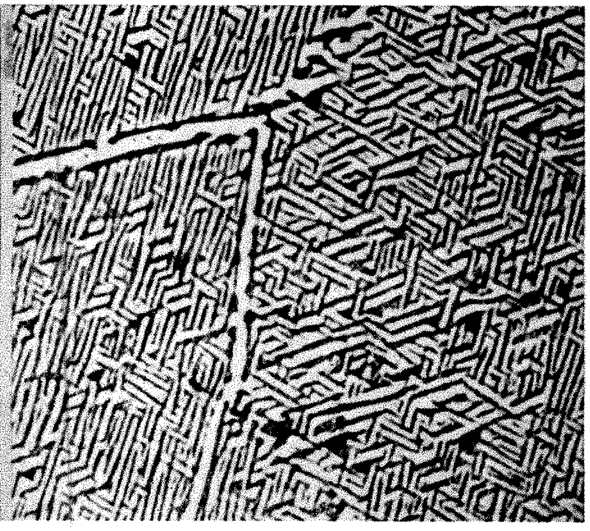

Fig. 2. Photomicrograph of alloy near composition Fe_2NiAl after annealing for 16 days at 850° C. Transformation point, 950° C. Polished and etched; magnification, × 2,000. Black: iron-rich magnetic; white: NiAl-rich non-magnetic. (After Bradley)

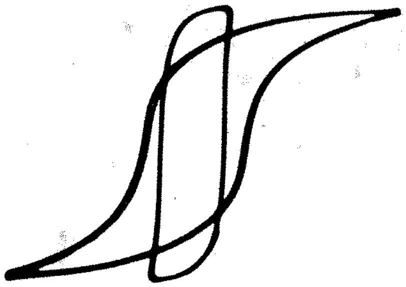

Fig. 3. Comparison of hysteresis losses for oriented and normal hot-rolled silicon–iron sheet. ($B_{\max}$ = 10,000 gauss; f = 50 c./sec.) Inner loop: 'Crystalloy' (oriented); outer loop: 'Stalloy'. (After Astbury)

iron-rich 'islands' can be regarded as subjected to compressive forces induced by the distribution of the largely non-magnetic nickel–aluminium-rich phase. The explanation of all the phenomena present is still imperfect but much progress has been made.

Mr. Astbury (Joseph Sankey and Sons, Ltd.) outlined the many important matters of detail in the achievement of highly oriented, cold-rolled 3 per cent silicon–iron electrical sheet-steel having low overall energy losses when subjected to alternating magnetization. The process, originally associated with the name of Goss, involves a sequence of cold reduction and intermediate heat-treatment which results in a well-defined rolling texture. These operations are followed by a high-temperature anneal, when the rolling texture, predominantly [110] (001), changes on recrystallization to [100] (011), which is similar to a single crystal having the magnetically favourable [100] direction along the rolling direction and the diagonal (011) plane in the strip surface[10]. Under the best conditions, losses of 0·28 watts/lb. at 50 cycles per second and an induction of 10,000 gauss have been obtained, associated with a maximum A.C. permeability of 22,000. The reduced losses and higher permeabilities are evident from the curves of Fig. 3, which compare at an induction of 10,000 gauss the normal hot-rolled silicon sheet ('Stalloy') with the new oriented material. Losses have been halved, and the initial and maximum permeabilities have been greatly increased.

The texture of the finished strip being all-important, four methods for its determination were outlined: (1) X-ray crystallographic methods, (2) optical methods (using reflexions from crystallographic etch pits), (3) strain anisotropy methods, and (4) magnetic methods. Typical results were shown, together with the final derived pole-figures. Finally, this able survey was concluded with a description of the best methods for arranging the lay-out and joints of practical magnetic circuits using anisotropic sheet materials so as to give maximum effective permeability and minimum overall losses.

In the discussion which followed, Dr. K. Hoselitz (Permanent Magnet Association) stated that changes in magnetization occurred by rotation and by boundary movements. In a permanent magnet material it was necessary to inhibit boundary movements, while in a soft magnetic material they should be encouraged; the presence of strain and non-magnetic inclusions prevented boundary movements. In the calculation of coercive force when rotations only are considered, high values were obtained; suggestions were made for refining the calculation Prof. L. F. Bates (University of Nottingham) expressed his interest in high-coercivity alloys and sai so much more could be explained if domain vecto were assumed to rotate only through angles n exceeding 90°. They had studied recently[11] the dependence of the value of Young's modulus (E) upo magnetization for the pure metals, iron, nickel an cobalt and for the permanent magnet alloy 'Alnico For nickel, under certain conditions, the change i E was 7 per cent; for 'Alnico' it was only 0·02 pe cent. Furthermore, the damping coefficient fo 'Alnico' rods in mechanical vibration were noted t be very small (of the order, logarithmic decremen equal to $2 \cdot 5 \times 10^{-4}$). The proposal was made tha these alloys might have uses as magnetostrictiv elements in filter circuits. Finally, mention was mad of remarkable time-lag effects in the measure hysteresis loop for 'Alnico' (in the vicinity of H_c He pointed out that time-lag phenomena might pla an important part in the heating and cooling effect observed[12] when a ferromagnetic metal is magnetize step-by-step. Dr. M. McCaig (Permanent Magne Association) referred to some experiments on th magnetostriction of anisotropic permanent magne alloys. He concluded that in such alloys domai magnetostriction is normally along the neares crystallographic 'easy' direction to the preferre direction. Prof. W. G. Burgers referred to Fig. taken from Bradley's recent researches and pointe out that Dr. J. L. Snoek[13] in 1939 observed th two-phase character of single crystals of Fe_2NiAl by a doubling of certain spots in the X-ray photographs. He considered the recent work greatl extended the earlier findings.

Dr. Shoenberg (Royal Society Mond Laboratory Cambridge) pointed out that superconductors behav magnetically in exactly the opposite way to ferromagnetic materials in so far that they tend to exclud from themselves all lines of magnetic force. Th phenomenon[14] is only observed within a few degree Kelvin of the absolute zero (less than 10° K.), an so far has remained an obdurate problem in met physics, defying theoretical solution. Kamerling Onnes first discovered the effect about 1911; bu most of the work on magnetic properties has bee carried out since 1933. It was certainly a matter f surprise to observe that the resistance of some meta such as mercury and lead disappeared complete when a certain temperature, called the 'critic temperature', was reached. Below this temperatu the resistance is certainly less than 10^{-15} of its valu at room temperature. When a magnetic field applied, screening currents are induced on th surface of the superconductor which are just stron enough to exclude lines of force from the metal owing to the zero resistance these currents cann die away, and the metal behaves as if it had ze permeability or diamagnetic susceptibility − 1/4 Even more remarkable, however, is the fact that the metal is cooled in a magnetic field, the lines force are suddenly excluded when it becomes supe conducting. This cannot be a consequence of ze resistance, so that the effectively zero permeabili must be regarded as a fundamental property. A interesting experiment due to Arkadiew was d scribed. If a powerful short permanent magnet released over a large superconducting metal surfa curved in the form of a shallow trough, the magn floats in stable equilibrium above the surface of th metal (curved sides to the trough of metal ensu stability in the finite case). The explanation given was that corresponding magnetic image-poles of like sign are induced in the pool of superconducting metal which therefore repel one another. The surface currents in a superconductor are associated with a penetration (λ) of about 10^{-5} cm. This value of penetration varies with temperature below the critical temperature, and, from the observed variation, information can be inferred about m/n, where m is the effective mass of the electron and n is the electron density. It was hoped that by studying the penetration effect, much further illumination will be thrown on the superconducting state.

In the brief discussion which followed, Prof. Bates elicited the nature of the Russian experiments which showed that the gyromagnetic ratio for a superconductor was unity, and this eliminated the action of electron spins in explaining this phenomenon. In reply to Mr. Oliver, Dr. Shoenberg explained that the superficial superconducting current probably fell off exponentially from the surface through the penetration distance; this had never been verified experimentally to his knowledge. RELATION OF BIOLOGY TO PROBLEMS OF CIVIL ENGINEERING

IN an age when the boundaries of science continue to expand rapidly, and even the general practitioner of a subject tends to 'know more and more bout less and less', such a conference as that on 'Biology and Civil Engineering", held at the Institution of Civil Engineering during September 21–23, has everything to commend it. The engineer preoccupied with inanimate matter is reminded, or made ware of, the influence of plant and animal life on his structures, in both harmful and helpful contexts. The biologist, for his part, is shown the creatures of is study in a severely practical and workaday etting.

Of the thirteen papers presented during the three days of the Conference, four were general papers dealing with various aspects of soil erosion and floods in relation to vegetal cover and to man's use (or abuse) of such cover. In the two contributions from New Zealand[1,2] there is presented, with many fresh facts from recent survey work of the Soil Bureau (Department of Scientific and Industrial Research), telling and circumstantial picture of land degradation under faulty practices and of current plans for rehabilitation. The point is made—and needs pressing elsewhere—that a country like New Zealand, possessing a 'youthful' topography, an erodible rock and soil mantle, and an erosive climate (intense downpours, strong winds and prolonged severe frost) could ill withstand any interference with its protective cover, much less the assault of too intensive sheep farming, combined with burning, over the past century; the less so since the natural vegetation had evolved in the absence of fire, grazing mammals and burrowing rodents, all of which were introduced by the European settler. Cleared and burnt forest, whether lowland conifer-broadleaf or highland beech (*Nothofagus* sp.), could not be held to sown pasture after the initial potash fertility had been dissipated, but reverted to shrub (typically *Leptospermum scoparium*) and bracken fern (*Pteridum esculentum*), which further firing and over-grazing would sometimes reduce to low-production swards of native oat grass (*Danthonia* sp.). The interrupted biological chain: imported rabbit – imported stoat and weasel – native bird depletion – reduced forest fruit dispersal: which has prevented tree species from re-occupying shrub land, is of special interest here. The valuable and extensive tussock grasslands suffered similar depletion and regression, including invasion by introduced species like gorse, sweet briar and broom, and such worthless native perennials as cotton plant (*Celmisia spectabilis*) at higher levels and *Nassella trichotoma* at lower. Reclamation work initiated under the Soil Conservation and Rivers Control Act of 1941 emphasizes the special value of willow and poplar in stabilizing slopes and in the structural plugging of gullies; and is making trial of seeding and fertilizing pastures from the air.

The other two papers discussed in some detail the more fundamental aspects of erosion, that is, of 'accelerated', which is essentially man-made, erosion. Long-term run-off experiments at the Agricultural Research Institute of the University of Pretoria are cited[3] to confirm the unique soil-holding value of *close-growing* vegetation—but not of clean-cultivated row-crops like maize—even at a high rate of run-off; also recent work by Ellison and others on the specific effect of falling rain-drops, which demonstrates their disintegrating action on soil aggregates (independently of any subsequent loss from run-off) and confirms the finding of earlier workers, like Lowdermilk, on their damaging potency for sealing over, in the space of two–three minutes, the soil surface pores. The point is made that whereas "erosional damage cannot be completely prevented by any other means than by the efficient use of vegetation", man's food and cash crops may necessarily fall far short of Nature's ideal covering, and consequently "the engineer must step in and help out the agriculturist with engineering methods of control, even if these . . . are only temporary and relatively ineffective".

Unfortunately, many of the necessary data for applying such methods are lacking or defective; for example, a reliable index of the erodibility of soils, safe velocities of flow over different types of vegetation and, especially, a dependable formula for expected water releases from small watersheds. Here it is remarked that the current trend is to apply probability analyses directly to actual measurements of rates of run-off, rather than use the rational formula $Q = CIA$, which seasonal variations in, for example, vegetal cover are apt to confound. These and other difficulties in applying the formula are discussed.

In the complementary paper[4], the protective action of vegetation, and especially of forest, against wind and weather is analysed in terms of the rough hydrological equation :

$$\Sigma = P - [I + E + T],$$

or discharge (streamflow) equals precipitation minus vegetal offset. Salient findings are that "vegetal cover removes more precipitation, physically and organically, than does evaporation from bare soil, that it both creates and maintains storage opportunity in the ground below it, and that it ensures conditions under which clean surface water can be absorbed at especially high rates". The modern forester and hydrologist, nevertheless, make no extravagant claims, for it is concluded that "vegetation should be looked upon as a *moderator* rather than a preventer of floods, as exercising a more important role as a filter and retardant, ensuring the minimum of soil loss and releasing flood water that is comparatively free from detritus, and hence of minimum destructiveness to human welfare".

The first of these findings is interestingly traversed, so far as transpiration is concerned, in a specialist paper[5] from Rothamsted, which quotes the results of recent experiments there on evaporation from grass, bare soil and open water surfaces. It is contended that the evaporation from vegetation is likely to depend more on the acreage than upon the integrated leaf area, since the large amount of latent heat necessary to cause it must come almost entirely from solar radiation. Measurements over a number of years show that evaporation from plentifully watered grass fluctuates with the weather in the same way as evaporation from an open water surface, but averages 20 per cent less in summer, 40 per cent less in winter and 30 per cent less in equinoctial months, most of this reduction being ascribable to the closing of stomata at night and their intrinsic resistance to vapour diffusion. These factors, it is suggested, may be applicable to any continuous leafy cover, for example, forest. Calculated values of evaporation from grassland, assessing soil moisture deficits on a basis of about 3 in. of available water, are shown to accord closely both with direct soil moisture readings and with recorded dates on which field drains started to run.

The remaining papers were concerned with the role of vegetation in certain special branches of civil engineering. To the railroad engineer[6,7] it is an invaluable, if somewhat tricky, ally in stabilizing his cuttings and embankments. Interesting points brought out include : (1) the increasing use of sewage sludge as a top dressing in place of soil, and as a quick stabilizer of slipping slopes ; (2) the recent recourse to carefully and widely blended seed mixtures for grassing ; (3) the marked promise of bituminous surface treatments—adapted from wartime aerodrome experience—for grassing slopes. The cold bitumen emulsion is sprayed in a thin skin over the soiled and seeded surface, preferably with a dressing of sand before and after, and results in a quicker and more deeply rooted flush of grass remarkably free of competing weeds. As regards other forms of vegetation, stabilizers now largely favoured include the common ivy and traveller's joy (*Clematis vitalba*) on steep chalk, the hardy and adaptable *Cotoneaster henryana*, an evergreen shrub brought from Central China, and locust (*Robinia pseudoacacia*), rowan, birch and oak among the trees, the locust proving particularly useful on clays.

In quite another context, vegetation still plays an indispensable part in the stabilizing of sand dunes[8,9] Among interesting features of present-day practice are the use of tree lupins and, in America, of sea-oat (*Uniola paniculata*) in place of marram grass as initial binders ; the sowing of annual lupins both to nurse other vegetation and to add stabilizing humus ; and the trials recently begun of seeding lupins and grass from the air. The management of stable dunes as forest rather than pasture finds general favour with the experts, who also stress the need for perpetual vigilance in maintaining an unbroken seaward front.

Vegetation is seen in quite a different light by the roads and buildings engineers[10,11] wherever clay below foundations gets invaded by roots. These, by their varied seasonal demands for moisture, cause large volume-changes in clayey soils and so endanger overlying structures. The problem is world-wide, but modern shallow foundations and the exceptional drought of 1947 have brought it into prominence in England, particularly on the heavy clays of the south-eastern half, which possess a liquid limit of some 70–80 per cent of dry weight. A series of levelling points established in June 1947 at Garston at various depths in grass-covered heavy boulder clay revealed a maximum vertical settlement of about 2½ in. On bare ground it will not exceed ½ in. ; near fast-growing trees it may exceed 4 in. For buildings on such clays, a minimum foundation depth of 3 ft. and no trees within root radius are considered prudent rules ; but with stability and amenity so much in conflict, an alternative under active investigation is the use of short-bored pile foundations spanned by beams carrying the external walls. In the case of roads, recent surveys by the Road Research Board show that damage is not likely to be serious except with trees, and then only in urban areas where they are set in paved footways or where the rainfall distribution is affected by concentrated building. Tentative recommendations include the avoidance of fast-growing species, like poplars, within 50 ft. of the carriageway on heavy clays ; the need for co-operation of biologists at the soil survey stage of all road planning is also stressed. Much more research is needed, discussion showed, on the precise water changes caused by root spread. A cheap, root-impenetrable membrane, to be introduced near foundations, should not, it is considered, be beyond modern scientific resource.

In the concluding papers[12,13], vegetation of a special sort—planktonic algæ—is viewed as a chronic and complex polluter of stored water and of the filters purifying it for human use. In open reservoirs, the abstracting of nutrients or of 'limiting' substances, like phosphates, from the replenishing source does not, in the opinion of the authors of the first paper, offer a full solution, nor does algicide treatment (which is liable to recoil biologically). For lowland Britain in particular, they stress the paramount need for minimizing thermal stratification with its inevitable de-oxygenating of the deeper water and the contaminating reactions that follow its seasonal disruption and overturn ; even in its absence, chemical stratification of biological importance may exist. To this end, the following suggestions for optimum reservoir design are, *inter alia*, offered (1) intake filters of 40–50 micron fineness to reduce accession of organic matter (the plankton pabulum) (2) orientation to maximum wind force ; (3) introduction of booms and baffles ; (4) multiple levels of draft; and (5) suitably located scum spillways. That the key to the pollution problem is better circulation of the water-mass finds support in the interesting case of the 60-ft. deep Hollis Reservoir in Trinidad[13]. Here there are marked wet and dry seasons, intense rainfall, small variation in temperature, whether diurnal or annual, and, owing to its sheltered position, very little wind. As a result, vertical water circulation is restricted to the upper 10–14 ft., with no seasonal overturn, and the consequent heavy bottom build-up of plankton may extend to within 5 ft. of the surface during the dry season. Further, the sub-aerobic layer at the 20–35 ft.-level, which includes *Anabœna*, *Merismopedia*, and *Oscillatoria* blue-green algæ, suffers an extensive upheaval whenever an influx of cold water from heavy rains under-penetrates it; this is followed by the death *en masse* of its plankton content, with dire results—particularly from *Oscillatoria*—for water purity and filterage. THE SIGNALS RESEARCH AND DEVELOPMENT ESTABLISHMENT, CHRISTCHURCH

THE Signals Research and Development Establishment of the Ministry of Supply held three 'open days' during September 22–24. This was the first time that S.R.D.E., as it is known, has opened its doors to the public to exhibit the work carried out there. It was fortunately possible for Mr. J. Freeman, Joint Parliamentary Secretary to the Minister of Supply, to attend and address the visitors on September 23.

S.R.D.E. has its origin in the Wireless Telegraphy Experimental Establishment which was formed at Aldershot in 1904. It was transferred to Woolwich in 1916 and became the Signals Experimental Establishment. Early in the Second World War, it was renamed the Signals Research and Development Establishment, and was moved to its present location in Christchurch in 1943.

The No. 10 Set is probably the best known of its war-time achievements. This is a multi-channel radio set, the first communication set of its kind to use centimetre waves. The set played an important part during the advance across the Netherlands and Germany. Field Marshal Montgomery paid a special tribute to it in a message he sent to the Radio Convention arranged by the Institution of Electrical Engineers in March 1947. S.R.D.E. also carried out pioneer work on what is now known as 'miniaturization'. During the War, radio sets became more and more complicated. At the same time, the Army was demanding smaller and lighter equipment. This problem could only be solved by giving detailed consideration to each of the very numerous components in turn, searching for new materials of superior properties, and ensuring that every part of a component was essential and was bearing its maximum safe load. The result was that some equipments were reduced in size to as little as a quarter or even a fifth of their previous bulk.

Another problem arose when the British armies commenced to fight in tropical jungles. Equipment which had given satisfactory service in Europe and North Africa rapidly succumbed to attack from moisture and fungus. Moisture barriers had therefore to be devised in all packaging for transport, and either round the complete items of equipment when in use, or else round the individual components in the equipment (thus providing either sealed sets or sealed components in unsealed sets). Time did not allow tests on these developments to be carried out in the jungle, so the jungle had to be brought to the Establishment, in the form of tropical chambers and similar testing facilities.

Pulse Code Modulation and Digital Computation

In the earliest forms of telegraphy, communication was made by on-off keying. This simple system is the basis of the very topical pulse code type of modulation which has created so much interest recently both in Great Britain and in the United States. An experimental equipment was shown demonstrating the transmission of speech using this method of modulation. In this system the instantaneous amplitude of the speech wave-form is sampled at discrete time-intervals (6,600 times per second in the equipment shown) and the amplitude of each sample is transmitted as a coded series of on-off pulses. At the receiver the incoming pulses enable the successive samples of speech to be built up to the level originally measured at the transmitter. With a five-unit code the amplitude of each sample can be indicated to the nearest of 2^5 or thirty-two levels.

Since the transmitted signals are merely on-off pulses, minimum demands are made on the linearity in the transmission equipment, whether radio or cable. Until the condition is reached where noise or interference obliterates a number of the received pulses, the latter can be reconstituted at the receiver to correspond exactly with those originally transmitted. For the same reason, in long links, unmutilated pulses can be regenerated at repeaters so that any cumulative effect of noise or interference can be eliminated. The speech quality obtained with various numbers of amplitude-levels was demonstrated. With only four levels the received speech was intelligible though of poor quality. When the full thirty-two levels were employed, good telephone quality was obtained.

Electronic counting techniques are becoming popular in many applications to electronic control systems. An example of a counting circuit developed at S.R.D.E. was shown in the form of a frequency-dividing circuit operating on the stepping counter principle. Designed to replace the multi-vibrator in such applications as frequency-standardizing equipment and quartz crystal clocks, it is capable of stable division ratios as high as 30 in a single stage incorporating a pentode and double-diode. When used with a suitable input amplitude limiter, it is insensitive to wide variations of input frequency and amplitude, and will tolerate changes in high-tension supply voltages of ± 15 per cent when dividing by 30 and proportionally greater changes at lower ratios, thus dispensing with the need for stabilized power supply.

Research on Radio Materials

Researches in the physics of materials were demonstrated by two exhibits, one dealing with nuclear magnetic resonance and the other with an investigation on the properties of thin films deposited on metals. The phenomenon of nuclear magnetic resonance arises from transitions between the quantum states of nuclear spin orientation relative to an applied magnetic field. The energy-level differences are such as to bring the radiation concerned into the low radio-frequency band. The method first described by Bloch[1] was used to show the hydrogen (proton) resonance in water at a frequency of 6 Mc./s. The sharpness of resonance is limited by magnetic reactions within the substance and, as the resonant frequency is directly proportional to the applied magnetic field, to non-uniformity of this field. However, values of Q as high as 50,000 for proton resonance in water have been obtained.

Nuclear magnetic resonance will undoubtedly be of value in the calibration and control of magnetic fields—by reference to frequency standards. The converse possibility also exists of using the effect to provide continuously variable oscillations and filters of relatively high stability in which the magnetic field is controlled by indirect means. It is the last aspect which is of particular interest to S.R.D.E.

Telemetry

The successful prosecution of research into the characteristics of high-speed projectiles can only be achieved by staging a large number of test flights, during which an accurate and detailed knowledge of the behaviour of a projectile and its mechanism is obtained. Equipment was shown which was developed specially for transmitting this essential data to the ground by radio link and recording it at the receiver in a form convenient for subsequent analysis. Typical of the quantities telemetered are accelerations, pressures, temperatures, electrical currents and voltages, positions of moving parts and the timing of events. In the S.R.D.E. telemetry equipment, the various parameters to be measured are dealt with in sequence at the transmitter in the projectile. The signal is received on the ground, where electronic switching circuits are provided so that the different data may be recorded on separate tracks by cathode ray tube photography. The equipment has been designed to be as versatile as possible; for example, in the receiver, which incorporates cathode ray tubes, facilities are provided for recording the same measurement simultaneously on the traces of separate tubes. In addition to increasing the reliability of the equipment, this procedure allows related parameters to be recorded in close proximity, so making interpretation of the results as simple as possible.

Quartz Crystals

Examples were shown of the different types of quartz crystal units used for frequency-control in Army signals equipment from 1928 to the present day. The results of research into the effects of X-ray irradiation of different cuts of quartz crystals were also shown.

The 'S' Spring

A new mechanical principle, as yet but partially explored, was illustrated by the 'S' spring. A stri of thin spring-steel is clamped at each end and the clamps are twisted in opposite directions, thu forcing the strip into an S-like form. By altering th angles of twist of the clamps the stiffness of th centre of the spring can be varied continuously fro a positive, through zero, to a negative range o values. Moreover, the movement of the centre poin is almost linear. A vibration table, capable of carryin loads of 100 lb., and supported on four 'S' springs was shown in action in the Durability Testin Section.

Radio Sets

(*a*) *Field Pack Sets.* A number of different type of portable transmitter/receiver sets, including thos used during the War, were shown. The most recen set is the Wireless Set No. 88, a compact equipmen weighing only 11 lb. with its batteries, designed fo use by infantry. It operates in the very high frequency band, is frequency-modulated, provides fou crystal-controlled channels and gives a range o 1½ miles over average country.

(*b*) *H.F. Radio Equipment.* A number of high frequency receivers were exhibited. One of these the *R*209, is a small communication receiver usin 'miniature technique', and contained in a complete sealed case. The receiver was shown working submerged in a water-tank. The receiver station of radio teleprinter station using carrier-frequency shi was demonstrated taking long-distance traffic.

(*c*) *Stabilized Oscillators.* For some years S.R.D.E has worked on the problem of stabilizing oscillato without using quartz crystal control. A stabilize oscillator having a constancy approaching that of crystal-controlled circuit was demonstrated. Nov vapour-pressure thermostats which have been foun necessary for maintaining constant the temperatu of the master oscillator were also shown.

Line Equipment

In the Line Laboratories a comprehensive arra was shown of Army teleprinters, switchboards, carri telephone sets and testing instruments. A pa ticularly interesting instrument is the pulse fau locator. This sends a radio pulse along a line in whi a fault, either a disconnexion or a short circuit, suspected. The pulse is reflected at the fault, becau this causes a discontinuity on the transmissi characteristics of the line, and returns to the s The time taken by the pulse to do the journey measured and the distance to the fault determine

Electro-Acoustics

Demonstrations were given illustrating the ada ability of the ear. Recordings showed that spee which had been seriously distorted in a number ways can still be intelligible. This was followed recordings taken over some transmission syste which apply various forms of controlled distortion order to improve intelligibility under adverse c ditions or to achieve economies in the transmissi path.

An exhibition of Army telephone instruments showed the evolution from the early sets to the latest efficient light-weight telephone set which is carried in a small webbing-pouch by the lineman.

Equipment and Component Testing

S.R.D.E. has a very well-equipped laboratory for testing component parts and complete sets. Every imaginable climatic test can be applied—heavy and tropical rain, sand-storms, low temperatures and pressures, even tropical storage, which includes typical fungi and mould growths. The rigours which Army sets must withstand were also demonstrated by vibration, bumping and dropping tests. Microscopy and X-ray examinations are used to assist in locating faults.

The G.O.C. Southern Command provided a display of R.E.M.E. mobile workshops. These are lorry vehicles provided with work-benches, test equipment and repair facilities ingeniously arranged to make the most of the limited space. By means of these workshops, Army signals equipment is maintained and kept in good repair in the field. R.E.M.E. personnel were shown at work repairing radio and line sets.

---

OBITUARIES

Prof. F. Weidenreich

THE distinguished anatomist Dr. Frank Weidenreich died after a short illness in New York on July 11, 1948, at the age of seventy-five. Although he was known to the present generation primarily for his work in the field of human palæontology, he had in the early part of his career gained a considerable reputation as a histologist. After taking his doctorate of medicine in the University of Strassburg in 1899, he joined the staff of the department of anatomy and studied under Prof. Schwalbe, and in 1904 he was appointed professor of anatomy. His interests at that time were concentrated on the blood-forming tissues of the body and he contributed a series of papers on the histology of the spleen and the blood-lymph system. Some of these papers, it is interesting to note, are still quoted as standard references.

At the end of the First World War, Weidenreich was compelled to vacate his position at Strassburg, and in 1921 he was appointed to the chair of anatomy at the University of Heidelberg. From that date he seems to have transferred his attention to problems of physical anthropology, mainly, it would appear, as the result of studies which he made on the structure of bone in relation to function. In 1921, he published an extensive monograph on the comparative anatomy and evolution of the human foot, and in 1926 he entered the field of human palæontology by a comprehensive study of the famous Ehringsdorf skull.

In 1928, Weidenreich was elected to the chair of anthropology at Frankfurt. This he held until 1935, when the difficulties of the political situation in Germany became too great. It was then that Weidenreich was invited to take the chair of anatomy at Peking Union Medical College, recently vacant by the death of Dr. Davidson Black. This appointment was combined with the directorship of the Cænozoic Research Laboratory of the Geological Survey of China. Dr. Weidenreich's energetic studies of the skeletal remains of the early type of fossil man, *Sinanthropus*, excavated at Choukoutien, are too well known to need recapitulation here. He produced a series of magnificent monographs, richly and profusely illustrated, which proved of the greatest value to anthropologists everywhere. Their value has now been even more enhanced by the fact that almost all the original material on which these monographs were based—material of supreme importance to the student of human evolution—was lost during the Japanese invasion of China.

Dr. Weidenreich himself was forced to leave China in 1941 in order to escape the invasion. He made his way to the United States, and was there offered hospitality in the American Museum of Natural History. Here he continued his researches, and published a number of articles in which he strove to integrate the results of his earlier studies in a constructive account of what to him appeared to be the probable sequence of human evolution. Shortly before his last illness, Dr. Weidenreich was engaged on an intensive study of the Solo skulls discovered in Java a few years before the War, and brought to America after the cessation of hostilities by Dr. von Koenigswald. This study was still unfinished, but it was rapidly approaching completion—sufficiently so, it is to be hoped, to make possible its publication in some form.

Weidenreich's life was one of intense and continuous intellectual activity, the more remarkable since his work was so often interrupted by the disruptive effects of wars and political dislocations. But he had an indomitable spirit, and his long series of scientific publications bears witness to the energy with which he pursued his intellectual inquiries, regardless of obstacles which would certainly have frustrated a lesser man. W. E. LE GROS CLARK

Dr. J. W. S. Macfie

BY the death of Dr. J. W. S. Macfie at the age of sixty-nine, tropical medical research has lost a worker of outstanding ability and high character. He was educated at Oundle School and at the Universities of Cambridge and Edinburgh, taking the degrees of B.Sc. and M.B., Ch.B. (1906), and later the D.Sc. After residence at the Radcliffe Infirmary, Oxford, and work in physiology under Sir Charles Sherrington, he took the diploma of the Liverpool School of Tropical Medicine in 1910 and joined the West African Medical Staff. He investigated sleeping sickness in Nigeria and took charge of the Medical Research Institute there. In 1914 he became successively pathologist in charge and director of the medical laboratory at Accra, Gold Coast, and held this post until his retirement in 1923, with an interval from 1917 to 1919, when he worked in Liverpool with Prof. Warrington Yorke and others on malaria. Shortly before his retirement he designed the plan of the present Medical Research Institute at Accra. He afterwards studied in Liverpool and London, accompanied Dr. Melly with the British Red Cross to Abyssinia in 1935, and during the Second World War had war duties in London and went to Egypt, Palestine and Syria as malariologist in the R.A.M.C. He was awarded the Mary Kingsley Medal by the Liverpool School of Tropical Medicine.

Macfie was a keen investigator with original ideas and a critical mind ; his laboratory technique was of a high standard, and his experiments seldom needed repeating. His researches in tropical medicine included protozoology (trypanosomes, malaria parasites, amœbæ), helminthology (schistosomes, filariæ, hookworms, guineaworm), entomology (mosquitoes, Ceratopogonine midges and other arthropods), and fungi (*'Nocardia'* or *Discomyces*). His articles and annual reports were written in a clear and attractive style, at times with a whimsical touch, and illustrated with excellent photographs taken by himself; an examination of paper money in Accra, for example, was recorded under "Filthy Lucre". He was much in favour of closer association between research workers in the Colonies and those in Britain, and even thought that a tour of duty might well be shortened by a month to be spent in one of the home laboratories.

It was my privilege to work with Macfie and his friend and colleague, the late Dr. Alexander Ingram, at the Accra laboratory nearly thirty years ago, and I then formed a very high opinion of his personal qualities. He was devoted to research, while not neglecting routine, and his outlook was quite uncommercial and free from self-interest. Though rather shy and reserved, he would firmly resist any moves which he thought would impair the efficiency of his department. The Gold Coast Government once offered him £500 in recognition of his work; but he declined it, saying that the laboratory work was done by the whole staff, and suggested that the money be given to assist further research. His health was never good and he could not stand a long tour of residence; but every day was filled with work and he grudged the loss of time when, as sometimes happened, interruptions were too frequent. He entered little into the general social life at Accra, but liked to entertain a few friends; as he was an excellent host and good companion, such occasions were very enjoyable. He took a great interest in original work by junior men, and would write helpful and encouraging letters to those working alone in out-stations. He was kind and sympathetic to his servants and staff and was liked and respected by them as, indeed, he was by all who knew him. His "Ethiopian Diary" is characteristic of the man. J. F. Corson

Mr. G. H. Gabb

George Hugh Gabb, who loved to style himself the 'Father of the Scientific Antiquaries', died on August 11, aged eighty years. He was educated at Bishops Hatfield School and later studied chemistry at the Polytechnic. He was for some time analyst to Welford and Son, and in 1892, in conjunction with Dr. Faber, he invented and put on the market the first type of humanized milk. Later he set up as a consultant on his own account. He retained an interest in public health, and, during a part of the period when he was a councillor of St. Pancras, was chairman of the Public Health Committee.

In 1885, Gabb became interested in the history of science and began to acquire his remarkable collection of scientific antiquities. He was at once a fine craftsman and a connoisseur. He had great understanding and sympathy with the instrument-makers and studied their crafts, thus becoming a master-hand at the treatment and conservative restoration of masterpieces. His understanding of the quality of early work enabled him unhesitatingly to detect forgeries and 'reconstructions'. As one of the first of collectors at a period when there was little interest in old scientific instruments, he was able to make a collection which consisted of really first-class specimens in perfect condition. Among his discoveries were the astrological astrolabe of Queen Elizabeth (*c.* 1570), the earliest dated English theodolite (1574) and the earliest known dated telescope (1646). His collection was acquired in 1937 by Sir James Caird, who presented it to the National Maritime Museum. Gabb was also an expert in the field of scientific iconography, and discovered many unknown or lost portraits of men of science, ranging from Galileo to Dalton. He was a severe critic in such matters and discredited many portraits accepted as genuine. His interests covered a wide field. He was an enthusiastic photographer, and the last survivor of a small group of X-ray workers who were experimenting in the years 1896–97; among his long succession of exhibits at the Royal Society's conversaziones was an X-ray photograph of his hand, made in February 1896.

Gabb was a remarkable character—a very typical collector, who would stick at nothing to acquire the instruments he coveted. He was by no means blind to his own qualities in this field, and his amusing conversation was not a little marred by its egocentric character. None the less, he was a mine of information and gave to his 'antiquarian sons' treasures of technique which could have been learnt nowhere else. To the Royal Society he left £1,000 to provide for a Leeuwenhoek Lecture on some subject in the field of microbiology; to the Science Museum a number of instruments of historical interest; to the University of Oxford, for the Museum of the History of Science, a collection of drug-jars and some sixty engravings and portraits; and to the Royal Institution a number of letters and relics of Michael Faraday.

We owe a great debt to George Hugh Gabb for his preservation for posterity of so many of the fast-disappearing relics of the great men of science on whose shoulders we stand. F. Sherwood Taylor

Dr. J. H. Shaxby

Dr. J. H. Shaxby, who died at Cardiff on September 29, was born at Ashford, in Kent, on May 23, 1879. After his schooldays at Canterbury, he studied at Aberystwyth and then at the Royal College of Science, London, where he became a demonstrator in physics and where he lost an eye in a laboratory accident. In 1904 he joined the staff of the Physics Department at Cardiff and eventually became director of the Viriamu Jones Physical Research Laboratory. In 1924 he relinquished that post when he was appointed lecturer in special sense physiology in the Physiology Department of the School of Medicine at Cardiff, a position which he held until he retired in 1946, but without severing his connexion with the Department. Among many other activities, he was a member of the Physiology of Hearing Committee of the Medical Research Council and was chairman of a committee of the Physical Society on Defective Colour Vision.

Shaxby's scientific interests covered a wide field. An early book of "Elementary Electrical Engineering" (1907) was followed by studies in Brownian movement. Then his service as an X-rays officer in the First World War led to papers on methods for localizing foreign bodies by X-rays. After the War he returned to more purely physical problems with work on vapour pressures and the isothermals of vapours, on the properties of powders, on the diffusion of suspended particles, and on the relation between density and temperature in fluids. An earlier interest in colour vision became dominant after about 1930 and culminated in two ingenious theoretical papers (*Phil. Mag.*, 1943 and 1946); but during the same period Shaxby was also much occupied with the physiology of hearing, and in particular with phenomena at the threshold of audition, and with the binaural localization of sounds. During 1932–35 he undertook long-range reception of gun-fire noises for the Air Ministry, and in 1937 he became interested in geomagnetic surveying, for which he invented a device for varying the sensitivity of the magnetometer.

This sketch by no means exhausts Shaxby's many interests even in the field of science. As a man, he was a most lovable and loyal colleague with whom it was a pleasure and a privilege to work.

T. GRAHAM BROWN

WE regret to announce the following deaths:

Dr. S. C. Bradford, until 1938 chief librarian of the Science Library, South Kensington, and founder, with the late Prof. A. F. C. Pollard, of the British Society for International Bibliography, on November 13, aged seventy.

Mr. R. Elmhirst, director of the Scottish Marine Biological Laboratory at Millport, whose forthcoming retirement was announced in *Nature* of October 30, p. 688, on November 13, aged sixty-four.

Prof. Karel Kavina, director of the Botanical Institute of the Prague Technical University for many years and known for his "Atlas of Fungi" (1927), a second enlarged edition of which appeared this year, aged fifty-eight.

Mr. E. Platt, geologist and leader of the Falkland Islands Dependencies Survey at Admiralty Bay, King George Island, South Shetlands, on November 9.

NEWS and VIEWS

Royal Society: Medal Awards

H.M. THE KING has been graciously pleased to approve the following recommendations made by the Council of the Royal Society for the award of the two Royal Medals for 1948:

Prof. Harold Jeffreys, for his distinguished work in geophysics and his important contributions to the astronomy of the solar system;

Prof. James Gray, for his distinguished researches in cytology, ciliary movement and particularly his anatomical and experimental studies of animal posture and locomotion.

The following awards of medals have been made by the president and council of the Royal Society:

Copley Medal to Prof. A. V. Hill, for his distinguished researches on myothermal problems and on biophysical phenomena in nerve and other tissues.

Rumford Medal to Prof. F. E. Simon, for his outstanding contributions to the attainment of low temperatures and to the study of the properties of substances at temperatures near the absolute zero.

Davy Medal to Prof. E. L. Hirst, for his outstanding work in the determination of the structure of sugars, starches, plant gums and especially of vitamin C.

Darwin Medal to Prof. R. A. Fisher, for his distinguished contributions to the theory of natural selection, the concept of the gene complex and the evolution of dominance.

Hughes Medal to Sir Robert Watson-Watt, for his distinguished work in atmospheric physics and in the development of radar.

British Astronomical Association:
Dr. J. G. Porter

MR. F. M. HOLBORN retired from the presidency of the British Astronomical Association on October 27 and was succeeded by Dr. J. G. Porter. Dr. Porter is well known in astronomical circles, not only in connexion with his broadcast talks, but also for his work for the Computing Section of the Association, of which he has been director for many years. He has also carried out investigations on the speeds of meteors and has shown that these bodies are members of the solar system, none of the cases that he has dealt with showing hyperbolic velocities; this would seem to dispose of the results of the Harvard College Observatory Expedition to Arizona some sixteen years ago.

Los Angeles State and County Arboretum:
Dr. Frans Verdoorn

DR. FRANS VERDOORN, managing editor of *Chronica Botanica*, has been appointed director of the Los Angeles State and County Arboretum at Arcadia, California. He will assume the directorship of this new arboretum in the immediate future. It is planned to develop a modern arboretum and botanical garden at Arcadia with various educational and research departments. Dr. Verdoorn will continue to edit *Chronica Botanica* and other journals. Some of these will be published in the future by the Los Angeles State and County Arboretum, while others will be transferred to a commercial publisher.

Dr. Verdoorn, a native of the Netherlands, went to the United States in 1940. Formerly known for his work in cryptogamic botany, he has lately been occupied chiefly with historical studies and international relations work. He was an assistant at the Buitenzorg Botanic Gardens, Java, in the 1930's and has been a research fellow at Harvard University since 1940. During the war years he did much work on Latin America and South East Asia for various government agencies. He received the first Mary Soper Pope Medal in 1946, and has just been appointed chairman of the International Phytohistorical Committee.

Control of Nationalized Industries

IN an address on "The Consumer in Relation to Non-Competitive Industry", delivered at the fifty-second Oxford Management Conference of the British Institute of Management held at Scarborough on October 16, Mr. Herbert Morrison said that increasing use of economists is being made in the work of government; but his address was chiefly concerned with the administrative policy pursued to protect the consumer in industries where full competition does not operate—a field which is not coterminous with that of public ownership. While under the competitive system the threat of withdrawal of custom could be a spur to efficiency, the corresponding safeguard with socialized industries should be their sensitiveness to public complaint. The consumer, he said, is entitled to demand that such industries avoid extravagant administration, attain a high degree of efficiency, pass to the consumer a substantial share of the results of higher productivity and have sufficient regard to the legitimate wishes of the consumer in matters of quality and variety.

Most of Mr. Morrison's address was devoted to an outline of the general organisation of the various public boards controlling certain industries in Britain, in which he stressed particularly the safeguards provided for the interest of the consumer. We have to rely on the various boards, Mr. Morrison said, to hold the balance fairly between consumer and worker, and he concluded that the consumer would be primarily dependent for a fair and reasonable level of price on the efficiency of the boards and their ability to keep both management and workers 'on their toes'. Such public boards should provide a reasonable safeguard against gross discrimination between consumers, but the address contained little evidence that the conditions Mr. Morrison specified are, in fact, being observed. It cannot now be seriously contended that even the Post Office passes on to the public the advantages in speed and efficiency which technical improvements have made possible, and the difficulties experienced in raising questions in the House of Commons regarding the public boards suggests that new means must be sought of making them sensitive to public opinion.

Australian Council for Scientific and Industrial Research

DESPITE grave misrepresentation of its motives, the Executive Committee of the Australian Council for Scientific and Industrial Research appears to have convinced the Commonwealth Government that scientific work for war purposes should be conducted under the Ministry of Supply or the Ministry of Defence rather than under the Council. The contention is that the conditions of secrecy and military security essential nowadays for war-work will require an atmosphere in which the normal activities of the Council on behalf of primary and secondary industry simply cannot flourish. The Council has for twenty-two years operated under an Act, originated by Viscount Bruce, giving it a high degree of freedom and independence; for many reasons it is believed that, in existing conditions, the two contrasting lines of work cannot be effectively controlled by the one body.

In providing for the transfer to another Commonwealth agency, under public service board control, of the small amount of work bearing on defence at present conducted in the laboratories of the Council for Scientific and Industrial Research, a Bill now before Parliament unfortunately goes further and opens the way for subjecting any or all of the Council's activities to public service board procedure and regulations. Strong exception is being taken by scientific men and societies in Australia to this action, which is regarded as a serious threat to the spirit and successful working which have characterized the Council for Scientific and Industrial Research in the past.

Australian Journal of Scientific Research

A NEW periodical of high standard, the *Australian Journal of Scientific Research*, has recently been launched by the Australian Council of Scientific and Industrial Research, Melbourne, in collaboration with the Australian National Research Council (see *Nature*, August 7, 1948, p. 210). It is being issued quarterly in two series, Series A (Physical Sciences) and Series B (Biological Sciences), the price of each being 7*s*. 6*d*. The editor and chairman of the editorial board is Dr. N. S. Noble, and the other members of the board are Profs. W. J. Dakin, E. J. Hartung, L. H. Martin and J. G. Wood.

The first number (March 1948) of Series A contains seven papers on physical, chemical, metallurgical and meteorological subjects, indicating the variety of researches undertaken or sponsored by the Australian Council of Scientific and Industrial Research. These include: an analytical treatment, by G. H. Godfrey, of the distribution of light intensity in the Fraunhofer diffraction pattern of continuous light sources, in which attention is directed to certain diffraction effects which have not been previously recorded but which are in agreement with the theory; a study, by V. D. Hopper and A. M. Grant, of the effect of a horizontal wall on the motion of oil drops, of radii 5–15 μ, falling in air, in order that the corrections to be applied in the precise determination of the electronic charge by the oil-drop method may be accurately made; observations on a strong variable source of radio frequency energy in the constellation of Cygnus; a microscopic and X-ray examination of the deformation or recrystallization of a duplex brass; and the testing of molecular layers of the silicones on various metal surfaces for their boundary lubricating properties.

German Scientific and Technical Periodicals

THE Foreign Office of Great Britain has recently compiled a list of more than three hundred German scientific and technical periodicals which have resumed publication. The list is divided into the following sections: agriculture and forestry; mathematics, physics and chemistry; medicine; natural science; and technology and industry. Very short notes, including the price where listed, are given with each periodical. Inquiries regarding the list should be made to the Foreign Office (German Section), Room 211, King Charles Street, London, S.W.1.

Financial Aid for Delegates at Conferences

THE British Council has a small fund for the assistance of overseas delegates wishing to attend national or international conferences held in the United Kingdom on scientific subjects including agriculture, engineering and medicine. Except in special circumstances, fares to and from the United Kingdom will not be paid, and the grants are mainly designed to cover subsistence of the delegate for the duration of the conference up to a period of two weeks. Conveners of conferences to be held during the period April 1, 1949–March 31, 1950, should apply to the Director, Visitors Department, British Council, 3 Hanover Street, London, W.1, giving full details including the number of delegates requiring assistance and their nationalities. Such information should be lodged preferably not later than January 15, and replies will be made by the end of February.

World Federation for Mental Health

THE World Federation for Mental Health, formed at the time of the international congress in London last August, has now been officially recognized for consultative purposes by the two United Nations bodies—the World Health Organisation and Unesco. The president of the World Federation, Dr. J. R. Rees (Great Britain), has expressed the hope that this consultative arrangement will lead to a further recognition of the importance of mental health in efforts to establish a healthier and happier world society. Dr. Rees also announced that the Federation has accepted the invitation of Unesco to send an observer to its general conference which opened at Beirut on November 17. The Federation is being represented by Dr. M. K. el Kholy, of Egypt, the member for the African Continent on the Executive Board.

The World Federation already comprises twenty-one mental health associations of different nations, and others are expected to be admitted to membership in the near future. Dr. André Repond, of Switzerland, now vice-president, in accordance with the by-laws of the Federation, will succeed Dr. Rees as president next year. Prof. H. C. Rümke, of Holland, is chairman of the Executive Board, which will meet in Amsterdam in January. Arrangements are also now being made for the Assembly of the World Federation to be held in Geneva next August, when delegates from all over the world will be present.

P. F. Frankland Memorial Lecture

THE Birmingham and Midlands Section of the Royal Institute of Chemistry is endeavouring to collect £1,500 to establish a memorial lecture in honour of Percy Faraday Frankland, who occupied the Mason chair of chemistry in the University of Birmingham with great distinction during 1894–1918 and who died two years ago. The lectures will be delivered in Birmingham at intervals of three to four years and will deal mainly with original work; they will be published and may be expected to make a notable contribution to chemical literature. All money subscribed goes to the endowment; cheques drawn in favour of "P. F. Frankland Memorial Lecture", crossed a/c payee, should be sent to Mr. E. M. Joiner (secretary, Birmingham and Midlands Section, Royal Institute of Chemistry), 15 Halton Road, Sutton Coldfield, Warwickshire.

Lantern Slides of Diagrams, Formulæ, etc.

IN *Nature* of June 29, 1946, p. 879, and several earlier issues, correspondents described methods they had used successfully for writing on glass. Mr. E. H. Leach, University Laboratory of Physiology, Oxford, states that any ink to which a drop or two of a solution of a synthetic detergent ('Teepol' type) has been added can be used for writing on any clean glass surface. Indian ink appears to be the most suitable. Some proprietary brands of ink appear to contain synthetic detergent and require no further addition. Glassware and microscope slides can be marked with such inks.

Hawaiian Libraries

MANY people are unaware that excellent libraries exist in Hawaii in conjunction with that country's museums, university, research institutions and archives of the Government. For information on the holdings of these libraries a "Union List of Serials in Hawaii" is being prepared; the Committee on the Union List, Hawaii Library Association, Honolulu, Territory of Hawaii, invites pre-publication orders at 3 dollars a copy.

Conference on Organised Information Services

THE Northern Branch of Aslib has arranged a conference on the general theme of the value of organised information service to industry, commerce and education, to be held at the North of England Institute of Mining and Mechanical Engineers, Neville Hall, Westgate Road, Newcastle-upon-Tyne, on December 7. The chair will be taken by R. Trevor Jenkins, technical manager, Vickers-Armstrongs, Ltd., Elswick and Scotswood Works, Newcastle-upon-Tyne. The conference will be opened at 10 a.m. by the Lord Mayor of Newcastle-upon-Tyne. Dr. V. E. Parke will speak on "Intelligence: Some Fundamental Principles", and will be followed by Mr. E. Austin Hinton on "Industrial, Technical and Commercial Information: The Contribution of the Public Library". In the afternoon session, at 2.30 p.m., Mr. R. O. MacKenna will speak on "Information Service from the point of view of the Universities", and will be followed by Mr. T. S. Nicol, who will deal with the point of view of professional associations. Miss J. Scurfield will speak on "The Regional Library Bureaux"; Miss E. M. R. Ditmas will deal with the work of Aslib, and Mr. R. Brightman with that of the Northern Branch. Conference tickets can be obtained (5*s*. each) from the local organising secretary, Mr. M. G. Cahill-Byrne, Vickers-Armstrongs, Ltd., Elswick Works, Newcastle-upon-Tyne, 4.

Comet 1948 l

DR. R. D'E. ATKINSON, who led the Royal Observatory eclipse expedition, cabled confirmation of a bright comet seen in the southern sky early in November. During the eclipse on November 1 a photograph showed that the comet was 1° 33′ from the centre of the sun, and it was then very bright with a tail. It has been seen in different parts of the southern hemisphere since then. Its brightness has been estimated as mag. 2. Its daily motion is approximately −8·1m. in R.A. and −51′ in declination. It is doubtful whether it will be seen from the British Isles. The latest description from the Cape Observatory states that the object is diffuse with central condensation or nucleus, and that the tail exceeds 1° in length; hence some of the Press reports about the length of the tail were probably exaggerated.

The Royal Observatory, Cape Town, has communicated the following parabolic orbit and ephemeris computed by Hirst and Stoy:

Elements

T	1948 Oct. 27·460 U.T.	
ω	106° 00′	1948·0
Ω	209 44	
i	22 48	
q	0·1296	

Ephemeris
0h. U.T.

Announcements

THE following higher degrees have been conferred by the University of Aberdeen: Ph.D., on G. F. Walker, for a thesis on "The Clay Mineralogy of some Aberdeenshire Soils"; M.D., on H. McL. Raffan, for a thesis on "Poliomyelitis in Aberdeenshire".

ERRATUM. Dr. Oscar Hechter states that the reference in the communication "Spreading Phenomenon and Inflammation" (*Nature*, October 30, p. 701) to earlier work (par. 4) should be to footnote 1, and not footnote 2 as appeared in his manuscript.

Clinical Potentialities of Certain Bisquaternary Salts Causing Neuromuscular and Ganglionic Block

Two members of the polymethylene $\alpha\omega$-bistrimethylammonium series[1] ($[N^+(CH_3)_3.(CH_2)_n.N^+(CH_3)_3]\ 2I''$) appear to possess activities which may be suitable for clinical use—the C 10 derivative ($n = 10$) to produce neuromuscular block, the C 6 derivative ($n = 6$) to produce ganglionic block. We wish to describe briefly the main characteristics of these compounds, in view of the great attention being paid to possible substitutes for *d*-tubocurarine chloride[2,3] and to the use of tetraethylammonium iodide for ganglionic block[4].

The accompanying table gives the doses of C 10 and *d*-tubocurarine chloride which are approximately equipotent in causing neuromuscular block when injected intravenously into unanæsthetized monkeys (*Macaca mulatta*), cats and rabbits.

	Monkey	Cat	Rabbit
d-Tubocurarine chloride (mgm./kgm.)	0·1	0·15	0·17
C 10 compound (mgm./kgm.)	0·3	0·03	0·10

These results show variation of potency of the C 10 derivative of the bistrimethylammonium salt with species (as we previously reported); preliminary trials indicate that man is close to the cat in sensitivity. The onset of the paralysis is smooth and uneventful in the monkey and the cat; in the rabbit, transient fine fasciculations (of the type reported in the cat under chloralose[1]) are just detectable. In general, the order in which the various muscles are paralysed and recover from paralysis is much the same as with *d*-tubocurarine chloride.

The main difference between the C 10 compound and *d*-tubocurarine chloride lies in the relative sparing of the respiration by the former in the monkey and the cat. In the monkey, even a small dose of *d*-tubocurarine chloride (0·075 mgm./kgm.), sufficient to produce weakness for about ten minutes, is accompanied by exaggerated movements of the nostrils and trunk indicative of respiratory difficulty. Similar respiratory signs can only be produced by the C 10 compound under test with a dose of 0·5 mgm./kgm., which causes complete paralysis of the animal for ten minutes, and weakness for an hour. Similar observations have been made in unanæsthetized and anæsthetized cats, and (to a less extent) in the rabbit. The ratio of the dose which just suspends respiration in half the animals to that which produces definite weakness for at least 10 min. has been estimated, as an index of the relative activity on respiratory and other muscles. In the monkey, the ratio is 2·6 for the C 10 compound, and 1·5 for *d*-tubocurarine; in the cat, the ratios are respectively 2·2 and 1·25. In the rabbit we have not been able to demonstrate any significant difference by this method, the ratio in both cases being close to unity. It is also noteworthy that the duration in the monkey of a paralysis due to the C 10 compound is usually two to three times longer than that of one of equal initial intensity due to *d*-tubocurarine chloride.

Eserine and prostigmine do not antagonize the C 10 compound; but a lower member of the series, C 5, has proved to be a useful antagonist. In all three species, an injection of 0·5–5 mgm./kgm. of C 5 cuts short a moderate or shallow paralysis, accelerates recovery from a deep curarization, and restores to normal a respiration that is becoming inadequate, where these conditions are due to the C 10 compound.

The C 10 compound must be compared with *d*-tubocurarine chloride in two other respects: (*a*) the latter is active in paralysing autonomic ganglia, and may thereby cause a small fall in blood pressure; the former exhibits some activity of this kind, but requires a dose five to ten times as great to produce the same effect; (*b*) the latter is known to liberate histamine[5], and such liberation might cause undesirable side-effects; the former can also be shown to produce an effect on the blood pressure characteristic of histamine liberation[6]; but it requires a dose at least four times larger. We have confirmed Barlow and Ing's[7] finding that this series of compounds possesses a weak anti-esterase activity; but this activity does not appear to produce any side actions, except possibly the fine fasciculations in the rabbit mentioned above. Chronic toxicity tests have shown that rabbits and cats can receive curarizing doses of the C 10 compound daily for six weeks without change in type or degree of the paralysis, or deterioration in the health of the animal.

As a possible substitute for *d*-tubocurarine chloride, therefore, this C 10 compound merits consideration, since it is both potent and can be antagonized; it also has the following advantages: (1) it spares the respiration; (2) it has less ganglionic action; (3) it has less power of liberating histamine; (4) it is a simple compound easily synthesized.

The C 6 derivative possesses great potency in paralysing autonomic ganglia, although it is inactive in other respects except in very large doses. Its effects, when injected in a dose of 0·1–1 mgm./kgm., are closely similar to those of tetraethylammonium iodide (paralysis of contraction of cat's nictitating membrane excited by preganglionic stimulation; fall of blood pressure, no longer obtainable after a paralysing dose of nicotine; paralysis of peristaltic reflex of rabbit intestine; paralysis of parasympathetic ganglia of the heart), and have been shown to be restricted to the autonomic ganglia. C 6 differs from tetraethylammonium iodide in its greater potency (ten to twenty times, according to test object), and in its slower onset and three to four times greater duration of action.

The C 6 derivative, therefore, offers possibilities of clinical usefulness in such fields as hypertension and vascular disease, whenever tetraethylammonium iodide has too brief or slight an action.

Details of the pharmacological investigations will be published in full elsewhere.

Tracer Phosphatase Determination in Tissue Sections

THE increasing use of radioactive tracers in biology demands methods for quantitative recording even in tissue sections. Autoradiography furnishes one method, either by simply placing the sections containing the radio-ions towards a photographic plate[1], or by covering the section itself with a film of photographic emulsion[2,3]. In this way α- and even β-rays can be recorded[4].

The Geiger – Müller counter, however, is still the best means for quantitative recording of β-rays. I have used a counter in the way described below to record the amounts of radioactive tracers in tissue sections as well as of tissue extracts according to established principles.

A Geiger – Müller counter, as described by Ambrosen, Madsen, Ottesen and Zerahn[5], is placed within a lead cylinder directly above an aluminium turntable with eight holes for small aluminium dishes which contain the radioactive material. The electrical details of the apparatus, which contains a regulated 2,000-volt power supply, a scale-of-16 and a scale-of-10, a registering device and an arrangement which makes it possible to make counts for each dish or slide automatically as long as desired within the limits of 2 minutes and 30 hours, has been described elsewhere[6].

When tissue sections are to be measured, they are mounted on polished slides and covered by a 'Cellophane' coverslip ; the sections are placed above the holes in the turntable, and by means of a microscope fixed to the apparatus their positions are controlled. Small brass plates, 1 mm. thick, with diaphragms of the desired diameters, ½–2 mm., are then lowered upon the slides and are kept in place by means of small pins fitting into holes in the turntable. Before the plates are pressed into position, it is checked by the microscope that the desired parts of the sections actually are centred beneath the diaphragms.

Now the Geiger – Müller tube with its lead cylinder is raised 2 mm. by means of a half-moon-shaped piece of lead which corresponds to the height of the slide plus brass plate, and the counting may begin.

As the brass plate directly covers the section, except for the 0·05 mm. thick 'Cellophane' coverslip, the amount of tissue in which the radio-ions are measured depends only upon the diameter of the diaphragm and the thickness of the section. Using a common diaphragm of 1 mm.[2] and sections of 5 μ, the amount of tissue under observation is only 0·005 mgm. Either frozen sections or paraffin or celloidin sections, stained or unstained, may be used. When possible, stained sections are preferred, as the histological examination and the radio-ion counting can then be undertaken in the same section.

As an example of the method, I have made a quantitative estimation of phosphatase in tissue sections by means of a modified Gomori[7] technique. The tissue, fixed in 80 per cent alcohol and imbedded in paraffin wax melting at 42°, is cut in 10 μ sections which are deparaffinized and incubated in a substrate of glycerophosphate containing radiophosphorus and calcium nitrate. The sections, which now contain radioactive calcium phosphate, can then be placed directly in the apparatus, and afterwards—or previously—be stained with cobalt according to Gomori. The Gomori technique thus affords a qualitative, and the method mentioned here a quantitative, means of estimating phosphatase in the same section.

A further report of the results will appear in due course.

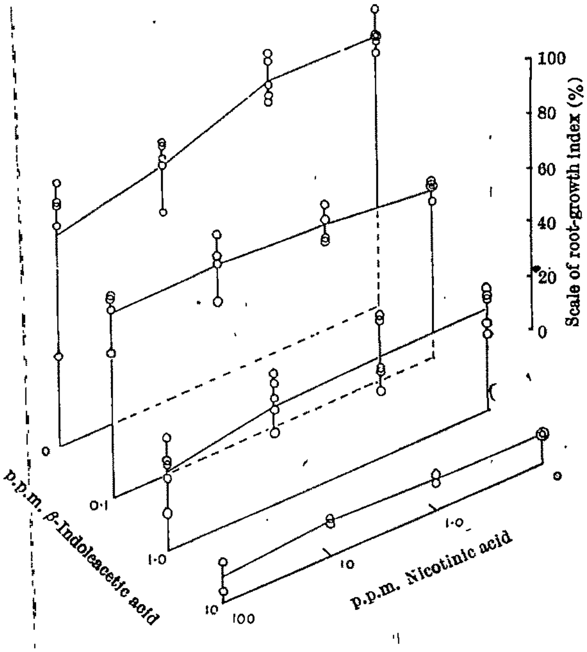
Nicotinic Acid and the Inhibition of Growth by Auxin

IN a recent paper, Galston[1] has shown that β-indoleacetic acid, at concentrations of 1–10 p.p.m., inhibits the growth in the dark of excised stem tips of *Asparagus*, in contrast to its normal stimulating effect in the light. Nicotinic acid, at a concentration of 0·5 p.p.m., was shown greatly to augment this dark inhibition, although without any effect by itself. These results were regarded as indicating that nicotinic acid is involved in the growth-regulating action of β-indoleacetic acid.

Recently, I have been studying the interactions with auxins of a wide range of plant metabolites in the growth inhibition of roots, and a considerable number of observations has been made with nicotinic acid. The technique employed has been fully described in a previous paper[2] and consists essentially of growing samples of cress seedlings in sterile water-culture in a number of different concentrations of the two substances both singly and in all possible combinations of those concentrations. Total root-



Three-dimensional diagram showing the interaction of nicotinic acid and β-indoleacetic acid in the growth-inhibition of cress roots growth per seedling was determined by weighing the fresh excised roots at the end of the experiment (7–10 days growth) and expressed as a percentage of the controls in the pure culture medium (root-growth index). The seedlings were grown in normal daylight. The results of a number of experiments are collected in the accompanying three-dimensional diagram. The two basal axes represent a grid of the various combinations of concentrations of β-indoleacetic acid and nicotinic acid, while the vertical axis gives the relevant values of the root-growth index.

It will be seen that nicotinic acid by itself brings about slight growth inhibition at high concentrations, but is without significant effect in any of the β-indoleacetic acid concentrations. It is possible that nicotinic acid may itself be, or may give rise to, an inhibitor of the auxin type in these high concentrations; but its effect is not detectable in the presence of the much more active β-indoleacetic acid. There is certainly no indication of any synergistic effects of the two substances, and this suggests that the phenomenon observed by Galston is not of general occurrence.

It is pointless with such meagre data to attempt an explanation of the discrepancy between two such isolated observations; but the above results suggest that the experiments of Galston should be repeated on an organ in which the inhibiting action of auxins has been much more intensively studied, such as the root. It is hoped eventually to extend the above investigations to excised roots growing, as in the case of Galston's stem tips, on a purely synthetic medium.

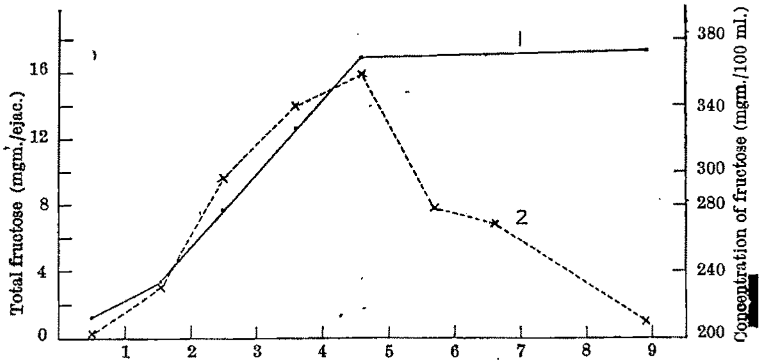
Relation between the Volume and Fructose Content of Human Semen

ESTIMATIONS of fructose content, by the method described by Mann[1], have been carried out on 150 specimens of human semen, obtained from 123 individuals. Of these, 41 ejaculates were obtained from 31 men of proved fertility, the remainder from men whose marriages had been involuntarily childless.

Considerable variation was found both in the concentration of fructose and in the total fructose content of the ejaculate. The concentration varied from less than 5 mgm. to 640 mgm. per 100 ml., with a mean value of 287 mgm. per 100 ml., while the total fructose ranged from less than 0·05 mgm. to 31·6 mgm., with a mean of 9·37 mgm. per ejaculate. The semen with minimum concentration, and also minimum total fructose, came from a fertile donor, as did the specimen with maximum concentration. That with maximum total fructose came from a childless man with a sperm density persistently less than 1 million per ml. Apart from a notable excess of good specimens and of fertile donors in the fructose range 200–500 mgm. per 100 ml. semen, no significant correlation was found between seminal fructose level and either sperm density or motility. This is not surprising in view of Mann's finding that azoospermic bull semen can be very rich in fructose, and that fructose is a chemical compound characteristic of the seminal plasma but not of spermatozoa as such.

On the other hand, a very interesting relationship was found between the fructose content of the semen and the volume of the ejaculate. As shown in the accompanying graph, the average concentration of fructose increases with volume, at first gradually, and then more steeply up to a maximum of 360 mgm. per 100 ml. in specimens with a volume between 4 ml. and 5 ml. With further increase in volume the concentration falls, specimens more than 7 ml. in volume having an average concentration of 209 mgm. per 100 ml. The total fructose content of the ejaculate also increases with volume, below 2 ml. at the rate of 2 mgm. per ml., and between 2 ml. and 5 ml. at the rate of 4·5 mgm. per ml. Above 5 ml. there is no appreciable increase of fructose with volume. It appears that the fructose-bearing secretion contributes the greater part of the extra volume between 2 ml. and 5 ml.; but further increments in volume are almost entirely due to the activity of other glands. Assuming that the majority of the fructose is produced by the seminal vesicle, the variation in volume and fructose content found in different individuals may well be the result of the marked variation in size of the seminal vesicle in man.

The ejaculate with highest fructose content in this series contained 31·6 mgm. of fructose in 8 ml. of semen. The highest concentration found was 640 mgm. per 100 ml., in a specimen of 4·4 ml. volume, and total fructose content of 28·2 mgm. It would seem that the maximum fructose output of the human seminal vesicle is about 30 mgm. of fructose contained in about 4 ml. of fluid of concentration 700 mgm. per 100 ml. On this basis the proportion of vesicular to other secretions could be worked out for any specimen of semen, an average specimen of 4–5 ml. volume being approximately 50 per cent vesicular secretion, whereas the seminal vesicles contribute only 30 per cent of the fluid in specimens less than 2 ml. in volume. However, Huggins and Johnson[2] found that in fluid obtained from the seminal vesicles by massage per rectum the copper-reducing substances varied from 275 mgm. to 625 mgm. per 100 ml., and it cannot be assumed, therefore, that the composition of the seminal vesicle secretion is approximately constant in sugar content.



Curve 1, variation of total seminal fructose with volume of ejaculate; curve 2, concentration of fructose

The volume of an ejaculate is to some extent affected by the time since the previous emission, and, in particular, specimens produced after intervals of less than 24 hours tend to be exceptionally small. In the present series 23 (47 per cent) of the 49 specimens with a volume less than 2 ml. were produced after an interval of less than 24 hours since the previous ejaculate. If the semen specimens are grouped according to time since previous ejaculate, at intervals of 24 hours, the average concentration of fructose remains constant after the second day up to the eighth day, the longest interval for which sufficient specimens were available to give a reliable value. The total fructose increases during this period in proportion to volume at the rate of 2 mgm. per ml. increase in volume. The mean fructose value for specimens produced with less than two days interval since the previous ejaculate is 250 mgm. per 100 ml., compared with 300 mgm. for specimens produced after longer intervals. The rate of increase of fructose with volume during the first two days is 5 mgm. per ml. increase in volume. These results suggest that the seminal vesicle in man is depleted to a much greater extent by a single ejaculation than appears to be the case in certain domestic animals such as the bull and the ram, and that a period of about 48 hours is required before the contribution of the seminal vesicle to the semen plasma, and therefore its fructose content, reaches the value characteristic of the individual donor.

It follows from these results that the volume of the ejaculate and the interval since previous emission must be taken into account in any attempt to correlate fructose content with other seminal characteristics, or to use fructose content as a measure of testosterone activity in man. Clearly no specimen produced within two days of a previous ejaculate can be relied upon to give a proper measure of fructose content. When the characteristic concentration has been reached, each specimen must be considered in relation to the mean fructose content of specimens of similar volume.

I am indebted to Dr. T. Mann for his instruction in technique, and his unfailing interest. The work was carried out with the help of a grant from the Medical Research Council.

Preservation of the Fertilizing Capacity of Bull Semen in the Genital Tract of the Cow

HEIFERS and cows with regular œstrous cycle were nseminated several hours (6–12 up to 48 hours) before the expected œstrus. The sperm used in these xperiments was collected from the two bulls of the artificial insemination centre; it was diluted 1/50 in odium citrate – egg yolk diluent and inseminated y rectal fixation of the cervix. In most of the ows the operation was executed very easily, and he insemination was made partly in the corpus uteri and partly in the cervix; exceptionally the ervix is insufficiently dilated, but penetration with the catheter was possible though more difficult than in the heat-period.

The beginning and the end of heat were noted by the owner; we did not control by rectal examination the exact moment of ovulation for fear of damaging the follicle; but we believe that ovulation takes place 10 hours after the end of heat in heifers and 16 hours in cows (Hammond).

In three of thirteen inseminated animals, the expected œstrus did not appear during the first days after insemination. Of the remaining ten animals, four returned in heat and were not pregnant; two of them were inseminated about 48 hours before œstrus; six animals (four heifers and two cows) became pregnant, which corresponds to the conception-rate for artificial insemination during the heat-period. Of these six animals, two were inseminated nearly 51 hours before ovulation, three were inseminated 45 hours before ovulation, and one was inseminated about 40 hours before ovulation.

Further experiments are going on with a larger number of cows; but these results seem to indicate that the sperm of fertile bulls, diluted with sodium citrate – egg yolk diluent and inseminated deeply in the cervix and the corpus uteri, may keep its fertilizing capacity, completely undamaged in the genital tract of the female at least up to 50 hours, even when this sperm has been stored for three days in the refrigerator.

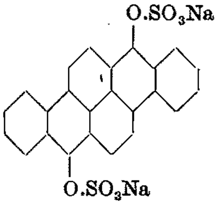
Inhibition of some Respiratory Enzyme Systems by Derivatives of Sulphuric Acid

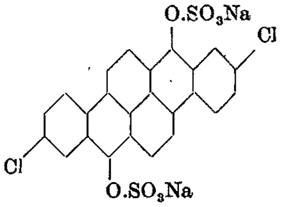
IN the course of work primarily concerned with the biological action of carcinogens, it was found that various sulphuric acid derivatives of large-molecule hydrocarbons strikingly inhibited certain enzyme systems when tested in Warburg respirometers. Substances I, II, III and IV (see over) inhibited the pyruvate-triose-phosphate system of rabbit skeletal muscle[1] by 87, 95, 94 and 50 per cent respectively, and the oxaloacetate-triosephosphate system of the same preparation by 68, 70, 53 and 10 per cent when added at $M/500$ in presence of 1/150 per cent extra cozymase. With extra cozymase the inhibition was decreased. It appeared to be competitive. Substance V was almost inactive at this concentration.

The first four compounds also inhibited the oxidation of lactate by ferricyanide[2] in presence of the Straub[3] lactic apodehydrogenase of bullock's heart muscle. The four inhibitors at $M/10{,}000$ in presence of 1/150 per cent added cozymase caused losses in activity of 52, 88, 20 and 21 per cent respectively. This effect was also diminished by extra cozymase. Substance V was again inactive.

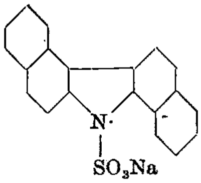
The first four compounds at $M/7{,}500$ also inhibited the oxygen uptake of a rabbit-liver homogenate in presence of succinate by 71, 70, 21 and 34 per cent respectively. Sodium methyl sulphate, sodium methane sulphonate and sodium α-naphthalene sulphonate gave no inhibition even at $M/300$.



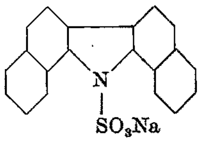
I



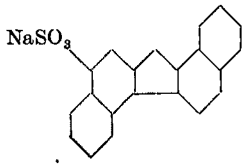
II



III



IV



V

It appears that the inhibitory activity may be primarily attributable to the presence of an O—SO_3Na or N—SO_3Na grouping (in the cozymase systems the action of substance II being possibly potentiated by the presence of two chlorine atoms in the molecule). On the other hand, the grouping C—SO_3Na seems to be inactive. The mode of action of the active compounds may be either direct competition with cozymase or some reaction entailing fission of the active groupings in the manner postulated by Crabtree[4] for chlorcompounds.

My thanks are due to I.C.I. (Dyestuffs), Ltd., for gifts of chemicals.

Enzymatic Degradation of Ribonucleoproteins of Chromosomes, Nucleoli and Cytoplasm

IN experiments utilizing purified crystalline ribonuclease in conjunction with various staining procedures, it has been possible to demonstrate that chromosomes of higher plants and animals contain appreciable quantities of nucleic acid of the ribose type. These experiments have also shown that ribonuclease may hydrolyse ribonucleoprotein, and that the residual material (non-histone protein) can be digested by pepsin. Conversely, ribonucleoprotein may be hydrolysed by pepsin, and the residual material (ribonucleic acid) degraded by ribonuclease. Such combination treatments have provided information concerning the localization of ribonucleoproteins, ribonucleic acid and non-histone proteins in nucleus and cytoplasm. The validity of these methods for diagnostic purposes rests upon the use of highly purified and carefully assayed enzymes, and the employment of an adequate series of controls to determine the influence of variables capable of modifying the histochemical reactions.

Results obtained by treating root-tip cells of onion and lily and salivary-gland cells of *Drosophila* serve to illustrate the potentialities of histochemical methods utilizing enzymatic hydrolysis. When sections or smears of these materials fixed in acetic alcohol are stained with Unna's methyl green – pyronin combination, the chromosomes are blue-lavender, the nucleoli and cytoplasm red. If hydrolysis by ribonuclease precedes staining, however, no component remains that colours with pyronin[1], so that cytoplasm and nucleoli are colourless and the chromosomes green. The possibility, inherent in earlier experiments of this type[2,3], that reduction in stainability might be referable to removal of proteins by protease-contaminated ribonuclease[4] has been obviated in these studies by the use of preparations of ribonuclease that are free from all measurable traces of proteolytic activity[5]. It can be concluded, therefore, that ribonucleic acid is present in chromosomes as well as in cytoplasm and nucleoli. Additional evidence leading to the same conclusion has been provided by the preparation of ribonucleoprotein from isolated chromosomes[6].

The use of fixatives particularly suitable for cytological studies, such as the fluids of Flemming and Navashin, makes possible staining procedures which cannot be used advantageously following fixation in acetic-alcohol. Thus the safranin – gentian violet – orange *G* triple stain, when used after the chrom – osmic – acetic acid fixatives, permits a pattern of differentiation in meristematic cells of root tips in which metaphase and anaphase chromosomes are bright red whereas the chromonematic threads of late telophases and early prophases are violet. Ribonuclease attacks this red-staining component, so that metaphase and anaphase chromosomes appear violet after hydrolysis. Prolonged treatment with ribonuclease also impairs stainability with the gentian violet component of the triple stain. These observations suggest that the ribonucleic acid of condensed chromosomes may be present in more than one form and that there occurs in the course of mitosis a cycle of accretion and dispersion of chromosomal ribonucleic acid which may be correlated with the appearance and disappearance of the nucleolus, and which is presumably related to the control of genic activity.

Flemming's triple stain has also provided a clue to the localization of the non-histone or tryptophane-containing protein[7,8]. It was found that cytoplasm chromosomes and nucleolus, after treatment with ribonuclease, show a density and brilliance of coloration with orange *G* that is not detectable in the controls. A similar colour intensification may also be obtained with other acidic dyes, such as acid fuchsin, light green and fast green. Thus, if sections are treated with ribonuclease and stained with fast green (using the Feulgen reaction for desoxyribonucleic acid to provide contrasting colour in the chromosomes), they will show an over-all intense and vivid green as compared with the pale green of undigested controls; but if the treatment with ribonuclease is followed by one with pepsin, the amount of green colour is then much less than that of the controls. Similar results are obtained when the nucleic acid is removed by Schneider's trichloracetic acid treatment[9]. These results indicate that ribonuclease can digest ribonucleoprotein, and that the protein thus freed stains intensely with acidic dyes and can be degraded by pepsin. Digestibility by pepsin suggests that this stainable material is non-histone protein[10]; its distribution within the cell, moreover, parallels that of tryptophane-containing material as determined by histochemical application of Bates' modification of the May – Rose test[1].

Ribonucleoprotein may be degraded by pepsin as well as by ribonuclease. If sections are treated with pepsin and stained in Unna's pyronin – methyl green combination, chromosomes, nucleoli and cytoplasm of the hydrolysed cells stain more intensely with pyronin than do those of unhydrolysed controls. If sections are treated successively with pepsin and ribonuclease, chromosomes, cytoplasm and nucleoli no longer stain red, indicating that the nuclease has removed the pyronin-avid material. These experiments indicate that ribonucleic acid may be present in fixed cells either free or combined as ribonucleoprotein, and that its stainability with pyronin is influenced by the state of association.

Such treatments, using combinations of enzymes, thus serve as a guide to an understanding of the affinity of certain dyes for specific cellular components. Other combinations of enzymes and dyes have been utilized in the study of a variety of normal and aberrant types of plant and animal cells. A detailed account of these studies will be presented in other publications.

Progress of this study has been facilitated by a grant from the United States Public Health Service, National Institute of Health, Bethesda, Maryland.

Giant Binary Stars and the Mass-Luminosity Law

It is well known that spectroscopic parallaxes are an index of stellar surface gravity, which in turn is functionally related to the mass and luminosity of a star. If, therefore, there exists a class of stars in which this functional relation differs from that found for the majority of stars, we should expect a lack of agreement of the mean trigonometric, dynamic and spectroscopic parallaxes of these stars.

In "The Masses of the Stars", Russell and Moore[1] directed attention to a serious discrepancy between the trigonometric and spectroscopic parallaxes of 52 visual binaries of the giant sequence. It is especially significant in view of the very excellent agreement of these parallaxes found for 641 *single* stars of the giant sequence. For the latter, the 'reduced' trigonometric and spectroscopic parallaxes are 0·0988″ and 0·0985″, respectively, whereas for the 52 double stars the corresponding values are 0·063″ and 0·095″.

The agreement of the spectroscopic parallaxes of the single and double stars is a strong indication that the surface conditions of these stars are, as a whole, identical. One is led to suspect a systematic error in the trigonometric parallaxes, yet none is obvious; none exists for double stars of the main sequence, and the discrepancy noted by Russell and Moore is not related to the separation or relative brightness of the components of the double star.

Acceptance of the trigonometric values places these stars about a magnitude above the regular giant sequence and, according to Russell, indicates a mass of about double that of single giant stars (mass-luminosity law). It is of particular interest that the increased mass would in this case be compensated almost exactly by the increased radius necessary to account for the greater luminosity, thus leaving the surface gravity unchanged. The giant binaries, then, would at once be over-luminous for their spectral class, sub-luminous for their mass, but of unchanged surface gravity. The observed agreement of the spectroscopic parallaxes of the single and double stars would thus be explained.

In view of the apparent failure of the mass-luminosity law in giant binaries, it is of interest to consider also the dynamic parallaxes of these stars, and secondly, to find whether the parallax discrepancy found for visual pairs exists also for spectroscopic binaries and for very wide common-proper-motion pairs.

The appeal to dynamic parallaxes is of special interest, for if giant binaries are sub-luminous for their masses, dynamical parallaxes derived for these stars should be somewhat greater than their trigonometric parallaxes, yet considerably smaller, numerically, than their spectroscopic values. This is observed to be the case: for 64 pairs for which trigonometric dynamic and spectroscopic parallaxes were available, the reduced values of these quantities are 0·065″, 0·075″ and 0·104″, respectively. Again, for 103 pairs for which dynamic and spectroscopic parallaxes were available, the respective values were 0·088″ and 0·114″. This latter discrepancy is, of course, totally independent of any possible error in the trigonometric parallaxes. No corresponding discordance occurs for main sequence pairs.

Spectroscopic binaries were also found to exhibit the discordance found for visual pairs: for 47 spectroscopic binaries, the mean reduced trigonometric and spectroscopic parallaxes were 0·079″ and 0·100″, respectively. However, for 34 very wide common-proper-motion pairs, excellent agreement in the mean for these parallaxes was found, thus perhaps relating these stars more closely to the single stars than to the closer doubles. That this agreement argues for a systematic error in the trigonometric parallaxes is not supported by the fact that in the closer pairs, for the most part, the components were far too faint, and of too long a period of revolution, to affect the measured parallaxes.

We can conclude, then, that the mean observed values of the trigonometric, dynamic and spectroscopic parallaxes of giant binaries are consistent with the hypothesis that these stars (the primary components) lie above the ordinary giant sequence but are subluminous for their masses.

Mixed Types of Stellar Populations

ONE of the most interesting and most mysterious features of the stellar contents of our own and other known galaxies is the fact that there seem to exist two rather distinct types of stellar populations differing between themselves by mechanical as well as by physical properties of individual members. In fact, as was first indicated by Oort[1], the so-called 'high-velocity' stars which describe highly elongated elliptic trajectories around the galactic centre seem to possess rather different physical characteristics as compared with the 'ordinary' stars predominating in the neighbourhood of our sun and moving along regular, almost circular, orbits. This distinction was amplified by the recent work of Baade[2], who has shown that the ordinary type of stellar population (which he calls type I) is characteristic only for the region of spiral arms, whereas the other type (type II) forms the structure of the galactic nucleus along with the tenuous, almost spherical, 'atmosphere' surrounding the entire system. All elliptical and spherical galaxies seem to be formed entirely from stars of type II.

The physical differences between the two stellar populations, as evidenced by the study of the corresponding Hertzsprung – Russell diagrams, can be summarized as follows: (1) the giant branch of the main sequences is completely absent in stellar population II; (2) the red giants of population II are different from those in population I, and are distributed along a continuous band which starts from the middle of the main sequence (the upper part of which is absent in this case) and is about one to three magnitudes above the ordinary red giant branch of population I; the number of type II red giants (relative to the number of dwarfs of the same spectral clan) is smaller in type II as compared with type I; (3) the lower part of the main sequence seems to be identical in both populations.

It has been also noticed that the percentage of double stars is two to three times lower among the stars of type II.

The understanding of physical differences between the two types of stellar population, and their relation to the difference of their motion and distribution within the galactic system, will undoubtedly throw much light on the general problem of stellar and galactic evolution. It is, therefore, especially annoying that hitherto we have not had any reliable theory of the internal structure of red giant stars capable of representing one of the principal differences between two types of stellar populations. For the same reason it is extremely important to collect all possible information concerning these stars and their possible relation to one of the two accepted types.

The results published by Dr. Hynek in the preceding letter seem to permit some interesting, though highly hypothetical, conclusions in this direction. Whatever may be the model on which the ordinary red giant stars are built, it seems very improbable that it could lead to the mass-luminosity relation, in which the doubling of the mass will increase the luminosity only by a factor of two. In fact, thermonuclear reactions which are responsible for the entire energy balance of the star must be expected to be much more sensitive to the internal temperature changes which would result from the larger total mass of the star. It seems, therefore, more reasonable to assume that the observed difference between the single red giants and those which are the members of a pair must be connected with the difference of their chemical constitution, their internal structure (model), or both. Since the same assumption must also probably be made to understand the difference between red giants of the types I and II, we could ask ourselves whether it is at all impossible to explain the facts stated by Dr. Hynek by assuming that red giants in the binary systems are essentially the stars belonging to the stellar population II? Indeed, the mean luminosity difference of about one magnitude between the single and double giants is comparable with the mean difference between the red branches of the two populations. Also the discrepancies between the spectroscopic and trigonometric parallaxes of single and double red giants which led Dr. Hynek to his conclusions are similar to the discrepancies observed by Morgan and Keenan[3] in the case of 'high-velocity' stars, inasmuch as they state that "high-velocity stars appear to be the only stars likely to cause serious trouble in using the method of spectroscopic parallaxes".

It must be remembered, however, that the binaries studied by Russell and Moore and by Hynek are, as a rule, the ordinary slow-moving stars which would be classed normally as type I. Thus, in making the above statement, we would be forced to accept the possibility of a mixed type of stars (type II_{I}) which possess the physical characteristics of type II but the motion of the type I. There may be also stars (type I_{II}) which look like those of type I but move as type II. Remembering that the correlation between physical properties and the type of motion of any individual star must be due to some events in the early history of its existence (formation process), and that the motion (as well as the family status) o a star may be changed by a number of externa causes, such an assumption does not look at al unreasonable.

New Localized Interference Fringes

IN this note a description is given of a simpl method for producing a new type of sharp localize interference fringes with interesting properties. Thes sharp fringes are best formed by multiple-bean interference, although a broadened variant can b obtained with two beams. They arise when a plan parallel sheet of flexible material silvered on bot sides is bent into a curve (suitable radii of curvatur are 1–5 cm.) and illuminated with strictly paralle monochromatic light from a point source, suc collimation of light being essential. The simples procedure is to flex a thin slip of doubly silvered mica into a cylindrical shape. In such a case straight-line fringes somewhat resembling those of a Lummer plate are the result. If the thin film is in the form of a spherical shell (for example, a blown thin film of glass) circular fringes form, resembling Fabry-Perot rings. Under suitable conditions, the fringes are critically localized and appear on a screen suitably placed. Both the mode of formation and the plane of localization are indicated by Fig. 1, where, for simplicity, refraction effects are disregarded. The detailed theory will be published elsewhere, and main conclusions only are given here.

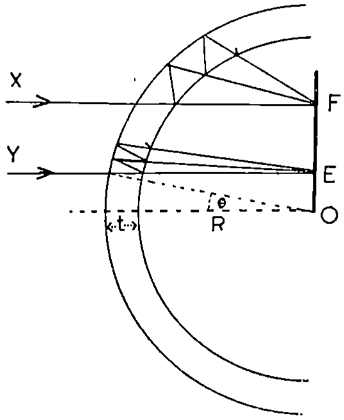

Fig. 1

Let parallel monochromatic light be incident from the left and let O be the centre of curvature. An incident ray Y is partly transmitted and partly reflected, and the successive beams all intersect at E. The multiply-reflected rays have a path difference $n\lambda = 2\mu t \cos\theta$, and at E, if the reflectivity is high, there is formed a sharp localized interference fringe with effectively an Airy intensity distribution, providing high values of θ, and small values of radius of curvature are employed.

In like manner, another incident ray X produces a fringe at F. Detailed analysis shows that a succession of fringes is localized nearly on the line OF, which is perpendicular to the direction of incidence. As in the Fabry-Perot interferometer analogue, the fringe 'radii' are here approximately proportional to the roots of the natural numbers, the diameter of the nth ring being approximately given by $2R\sqrt{\lambda(\varepsilon+p-1)/t}$, in which R is the radius of curvature, t the film thickness, ε the fractional order of interference at the centre and λ the wave-length.

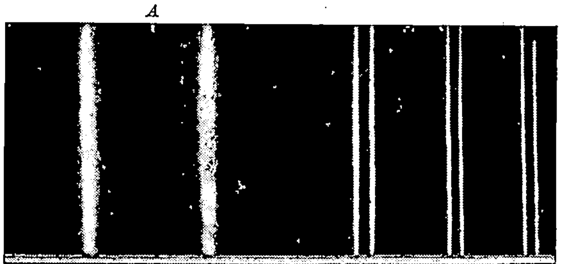
An example of the fringes so obtained is shown in Fig. 2, which are transmission fringes from cylindrically bent mica. They can be seen either on a ground-glass screen placed in the plane OF or with a lens focused on this plane.

Attention may be directed to the following features:

(1) Extreme sharpness, due partly to the high angle of incidence improving the effective reflecting coefficient.

(2) These particular fringes are double, the doubling depending on direction. This is due to birefringence of the mica, the doublet fringes which emerge being plane polarized, mutually perpendicularly, although non-polarized incident light is used. In Fig. 2 the centre of the system is at A.

Fig. 2



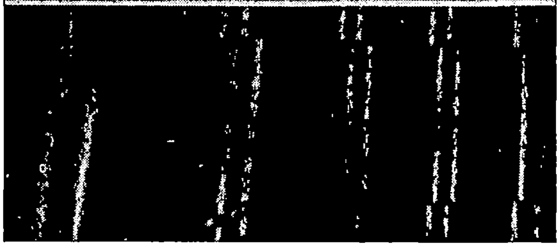


Fig. 3

(3) Under suitable conditions, that is, correct flexure of the specimen, two directions are found in which there is no birefringent doubling.

(4) Cleavage steps in the mica. These reveal their presence, and precision measurements on steps can be made, an example of such steps being shown in Fig. 3.

The fringes can be formed both by transmission and by reflexion. In the latter, tolerably sharp outer fringes are given by *unsilvered* films, because of the increase in reflecting coefficient at the higher angles of incidence. When silvered surfaces are used, the outer transmission fringes (higher angles of incidence) show additional complexity due to differential phase change effects, which lead to alteration in the birefringence doubling separation. Although a detailed analysis of the properties of the fringes in general, using both isotropic and crystalline media, is being communicated elsewhere, we suggest here a name to describe this new interference. It is proposed to describe the fringes as 'fringes of equal tangential inclination'. This is a fitting nomenclature since each fringe originates at the locus of points at which the incident rays all make the same angle with the tangents at the points of entry. The proposed name fits aptly into the accepted classical terminology for the other two types of fringes formed by a thin film with monochromatic light already long recognized, namely, the fringes of equal inclination and the fringes of equal thickness.

It may be noted that these precisely localized, sharp fringes, given here by a strictly parallel incident beam which suffers multiple reflexions, differ entirely both as to character and localization from the broad, confused, expanding, non-localized, elliptical fringes obtained by Raman and Rajagopalan with a widely diverging beam and a piece of unsilvered bent mica[1].

Low-Level Atmospheric Ducts

During 1943–46, the Signals Research and Development Establishment operated a series of experimental centimetre-wave radio links along a 60-mile oversea path across Cardigan Bay. One major purpose of the investigation, which was carried out for an inter-Service committee under the chairmanship of Sir Edward Appleton, was to determine the degree to which meteorological factors affected microwave propagation and to find out to what extent the performance of such links could be predicted from synoptic data.

In addition to the taking of continuous records of radio field-strengths, frequent measurements were made of temperature, pressure, humidity and wind velocity at the two terminal stations at Strumble Head in South Wales and Aberdaron in North Wales. We have found a fairly definite correlation between the radio field-strength and the difference between air and sea temperatures, particularly when this difference was large, for the lowest link, in which the transmitting and receiving aerials were each about 100 ft. above sea-level. Figs. 1 and 2 show the results obtained on a wave-length of 9 cm. for those periods during the twelve months from July 1945 to June 1946 when the difference between the air and sea temperatures was greater than 5° F. It will be seen from Fig. 1 that when the air temperature was more than 5° F. lower than that of the sea, a condition which obtained mainly on cold days, the field-strength usually lay between 20 and 30 decibels below the free-space value. When, however, on warm days the air temperature was more than 5° F. higher than that of the sea, the field-strength was approximately equal to the free-space value. These two field-strengths, corresponding to cold and warm days respectively, although differing appreciably, are both well above the field-strength of 70 decibels below the free-space value which would be expected on the assumption of standard atmospheric conditions for this link, which was 2·3 times the optical range.

A study of the radio results according to modern radio-meteorological theory[1] suggests that the high field-strengths in Figs. 1 and 2 are due in both cases to the presence of so-called atmospheric ducts lying directly on the sea surface. For the conditions corresponding to those in Fig. 1, the heights of the ducts appear to vary between 20 ft. and 50 ft., while for the higher field-strengths in Fig. 2 the duct heights are greater and lie between 80 ft. and 120 ft. The ducts which give rise to these high field-strengths are due singly or to a combination of a temperature inversion and a rapid decrease with height in the water-vapour pressure in the atmosphere. The presence of the low ducts of 20–50 ft. when the air (at 100 ft. above sea level) is colder than the sea is not easy to explain. It was noted that the cold conditions giving rise to these particularly low ducts were associated frequently with high wind when, incidentally, the radio signal was found to be particularly steady. We would suggest that these ducts may be due to the presence of sea spray whipped up by the wind, either directly as constituting an increase in the water content in the lowest air strata, or indirectly as a means by which evaporation is assisted in these strata by the presence of the spray. The atmospheric moisture required to form the higher ducts necessary to satisfy the field-strength values in Fig. 2 during warm weather can be explained by evaporation from the relatively cold sea.

This relation between the radio field-strength and the difference between air and sea temperatures was studied first by Mr. H. Jarkowski, when he was in charge of the running of the Welsh stations. We regret that as he is now in Poland his name cannot be added to this note without causing undue delay. We are indebted to the Chief Scientist, Ministry of Supply, for granting permission to publish this note.

Elastic Constants of Alum Determined by a New Ultrasonic Method

Following our work on the diffraction of light by ultrasonic waves in glasses described in an earlier communication[1], we have now obtained similar patterns in crystalline media, thus enabling us to devise a new method for determining the elastic constants.

Transparent and flawless specimens are suitably cut and polished, and stationary sound waves are maintained along specific directions of propagation. In cubic crystals, the cube and the octahedral axes are the most suitable. An X-cut or a Y-cut quartz plate is cemented on the surface of the polished prism according as it is desired to send longitudinal or transverse sound waves respectively. The sound velocities are then determined in each case in the usual manner by photographing the diffraction patterns at known frequencies. The effective elastic constants for specific directions are then calculated and the principal values deduced. Results obtained for alum along with those reported earlier by Voigt[2] and by Sundara Rao[3] employing other methods are given below in units of 10^{11} dynes/cm.^{2}.

	C_{11}	C_{12}	C_{44}
Authors	2·54	1·07	0·84
Voigt	2·43	1·009	0·843
Rao	2·56	1·07	0·86

As the measurements involved are of simple lengths, a high degree of accuracy can be obtained in this method by employing frequencies greater than 50 Mc./sec. The method is capable of being extended to a study of the dependence of elastic constants on temperature. Each crystal has, however, to be cut and polished to a high degree of perfection for a successful application of the method.

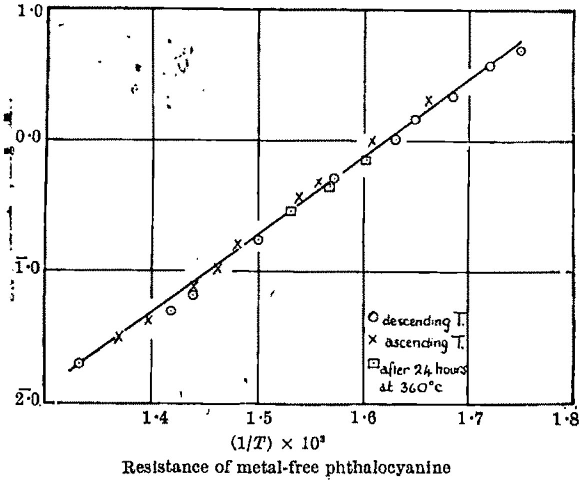
Phthalocyanines as Semiconductors

IN recent years Szent-Györgyi has directed attention to the possible importance of the electrical properties of organic molecules in biochemical catalysis[1] and has given evidence for photoconductivity in gelatin[2]. An approach to the theory in trans-conjugated polyenes has been indicated by N. S. Bayliss[3]. Hoping to obtain a system suitable for quantitative investigation, I have examined the electrical conductivity of two phthalocyanines. These substances, described by Linstead and co-workers[4], form a group of conjugated structures closely related to the biologically important porphyrins. They are particularly suitable for a research of this kind, because of their high degree of involatility and thermal stability. Their crystal structures are known from the work of J. M. Robertson[5].

Crystals of metal-free phthalocyanine and its derivative, copper phthalocyanine, have been examined in a 'Hysil' conductivity cell between platinum electrodes of area 2 sq. cm. separated by 2 mm. approximately. The crystals as packed in the cell had a bulk density of about 0·2. Hydrogen was circulated through the cell and its resistance measured as a function of temperature with a 'Megger'.

Both phthalocyanine and copper phthalocyanine have been found to be semiconductors. The accompanying graph shows the results for sample 1, I.C.I. metal-free phthalocyanine purified by sublimation *in vacuo*. It is clear that the results fit the well-known formula, $\rho = \rho_0 \exp E/RT$, where ρ is the resistance, R the gas constant, and E an 'activation energy'. The curve was quite reversible, and the sample was unaffected by 24 hours heating in hydrogen.



Resistance of metal-free phthalocyanine

Table 1. Metal-free phthalocyanine

Sample	$\log_{10} \rho_0$ (megohms)	E, k.cal.
(1) I.C.I., sublimed *in vacuo*	$\overline{10}$·24	27·6
(2) ,, ,,	$\overline{10}$·47	27·6
(3) I.C.I., sublimed in nitrogen	$\overline{10}$·08	29
(4) From Prof. R. P. Linstead	$\overline{10}$·35	27·6

Table 1 shows values of ρ_0 and E for four separate samples. The relatively small differences may be attributed to differences in the size of crystals and their packing in the conductance cell. It is very unlikely, in view of this reproducibility, that the semiconductivity of metal-free phthalocyanine arises from impurity centres. Metal-free phthalocyanine would appear to be an intrinsic semiconductor[6].

Two specimens of copper phthalocyanine were found to give qualitatively similar behaviour to metal-free phthalocyanine. However, both specimens showed some decrease in resistance and activation energy on heating in hydrogen at about 400° C. After twenty-four hours of such treatment a moderately steady state appeared to be reached, although a little hysteresis was still to be noted on the $\log_{10} \rho$ *vs.* $1/T$ curve, between values for ascending and descending temperature. The data in this state are summarized in Table 2.

Table 2. Copper phthalocyanine

Sample	$\log_{10} \rho_0$	E, k.cal.
I.C., sublimed *in vacuo*	$\overline{11}$·04	29·4
From Prof. R. P. Linstead	$\bar{7}$·1	20·7

While copper phthalocyanine does *not* require heat treatment to show semiconductivity, such treatment does have a modifying effect, and the two samples show quantitatively different behaviour. It is possible that impurity centres play a part here.

Considering the simple case of metal-free phthalocyanine, we may suppose that the electrons lie in energy-bands common to the whole crystal, arising perhaps by intermolecular overlap of the π-orbitals of the porphyrin rings. The observed activation energy of 28 k.cal. is then one half the energy gap between the full ground-band and the empty first excited band[7].

My thanks are due to I.C.I. (Dyestuffs Division), Ltd., and Prof. R. P. Linstead for the gift of specimens.

Utilization of Wheat Bran for Streptomycin Production by *S. griseus*

THE study of the nutritive requirements of *Streptomyces griseus* has assumed great importance on account of the remarkable activity of streptomycin against a number of bacterial infections. A number of media in which successful antibiotic production takes place have been recorded in the literature[1-5]. During the course of investigations on streptomycin production, aqueous extracts of wheat bran were found to give encouraging results; the methods of preparation and composition of the extract are described elsewhere[6]. By the procedure employed, about 4,000 ml. of the extract with about 3 per cent total solid content can be prepared from 1,000 gm. of bran.

The experimental procedure adopted was the one described previously[6]. The total solids of the media were adjusted to 0·5, 1·0, 2·0 and 3·0 gm. per 100 ml., and the *p*H to 6·5–7. A Waksman's strain of the organism was used. Daily observations of the antibiotic contents and the change in the reaction of the culture fluids were made (see Table 1).

Table 1

Total solids in medium	Reaction of medium						Streptomycin in μgm. per ml. days					
	3	4	5	6	7	8	3	4	5	6	7	8
0·5 gm./100 ml.	6·9	7·3	7·4	7·6	7·9	7·9	29	36	98	89	85	78
1·0 ,,	7·1	7·4	7·6	7·7	7·9	7·9	29	35	108	110	108	99
2·0 ,,	7·1	7·2	7·6	7·7	7·9	7·9	32	69	111	114	109	92
3·0 ,,	6·9	7·2	7·4	7·6	7·8	7·9	25	32	69	93	117	103

These data show that good production of antibiotic takes place even when the total solids in the medium are reduced to about 1·0 gm. per 100 ml. Further, 1,500–2,000 μgm. of streptomycin is formed for each gram of the bran used.

Different additions in the form of minerals, nitrogenous and carbonaceous material were then made to the basal wheat bran extract medium and their effect on antibiotic production was studied. Addition of small amounts of sodium chloride to the media increased the antibiotic production, as may be seen from Table 2.

Table 2

Composition of medium		Streptomycin in μgm. per ml. (days after seeding)						
Wheat bran extract	Sodium chloride	2	3	4	5	6	7	8
100 c.c. containing 1 gm. of total solids	0·5 gm.	75	126	160	95	73	68	63
	1·0 ,,	66	148	178	93	88	82	77
	2·0 ,,	46	161	163	98	98	83	82
	4·0 ,,	15	73	78	58	53	43	32
	5·0 ,,	15	40	78	70	65	45	33
100 c.c. containing 2 gm. of total solids	0·5 gm.	40	189	159	137	108	95	86
	1·0 ,,	52	179	203	138	123	86	76
	2·0 ,,	45	169	98	89	75	68	58
	4·0 ,,	23	85	93	93	60	54	33
	5·0 ,,	15	18	45	52	53	33	35

Concentrations of about 1 per cent appear to be the optimum. Higher ones are definitely harmful. In a medium containing sodium chloride, the antibiotic production is not only increased but also quickened. Observations of a similar nature regarding the role of sodium chloride have been recorded by Cook *et al.*[7] for penicillin production in pea extracts, and by Reke *et al.*[4] for streptomycin formation in soya-bean meal medium.

Wheat bran thus appears to serve as a cheap raw material for streptomycin production. Results of detailed investigations on these studies will be recorded elsewhere.

My thanks are due to Dr. K. M. Pandalai for helpful suggestions, to Prof. V. Subrahmanyan for his interest, and to Merck and Co., Rahway, N.J., for the standard streptomycin kindly supplied by them. I also acknowledge the financial support of the Council for Scientific and Industrial Research, India.

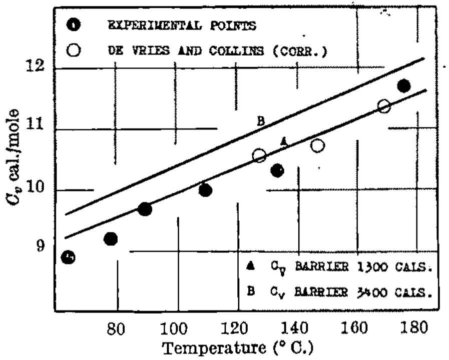
Heat Capacity of Methanol Vapour

CRAWFORD[1] has directed attention to a discrepancy between values assigned to the height of the energy barrier restricting the internal rotation in methanol. Such rotation is infra-red active, and spectroscopists have inferred that the barrier is 1,300 cal./mole. This would require the entropy at 25° C. and one atmosphere to be 57·62 E.U., while the observed value is 56·63 ± 0·25 E.U. Crawford pointed out that the discrepancy would disappear if the barrier were 3,400 cal./mole.

Independent information about the height of the barrier may be obtained from the heat capacity of the vapour. There is only one modern calorimetric measurement[2]. No attempt was made to correct for deviations from the gas-laws, and the results show an anomalous rise below 120° C. which was attributed to a dimerization of the vapour. New measurements of the heat capacity have been made between 64° and 176° C. by measuring the velocity of supersonic waves of frequencies 570 and 1,200 kc./s. The apparatus was that of Alexander and Lambert[3]. No dispersion of the sound was observed, the absorption was negligible and the observed value of the heat capacity was the same at each frequency. Under these conditions, the method is reliable (cf. Telfair[4]). At each temperature measurements were made over a range of pressure, and the 'ideal velocity' found by extrapolation to zero pressure. The results are, therefore, independent of any assumptions about the equation of state of the vapour.

The accompanying diagram shows both the experimental points and the values of the heat capacity



Heat capacity of methanol vapour

corresponding to barrier heights of 1,300 and 3,400 cal./mole. The latter were calculated by using the vibrational assignment recommended by Herzberg[5], the bond-lengths and angles given by Crawford[1], and the tables of Pitzer and Gwinn[6]. They are unlikely to be in error by more than 0·15 cal. The results obtained above 120° C. by de Vries and Collins[2] have been corrected by the Berthelot equation and are also included in the diagram.

The experimental results favour the lower (spectroscopic) value for the barrier height. This would indicate that the entropy discrepancy of 1·0 ± 0·25 E.U. is real. Pauling[7] showed that a similar discrepancy of 0·8 E.U. for ice could be accounted for by assuming a 'residual entropy' at low temperatures due to a completely random orientation of hydrogen bonds. Methanol may be similar. Unfortunately, the crystal structure is not known; but an infinite lattice with every oxygen atom tetrahedrally coordinated to one methyl group (covalency) and three other oxygen atoms (H-bonded) would allow each molecule to arrange its OH bond in three equivalent directions. The chance that its neighbours would permit any given orientation is 2/3. In *complete* disorder, such a lattice would have a residual entropy of $k.\ln 2^N = 1{\cdot}37$ E.U., which is adequate to account for the observed discrepancy. The lattice assumed is in agreement with the X-ray diffraction data for the liquid at − 75° C.[8].

It is interesting that there is a disagreement about the barrier height for methylamine[9], which might have a similarly disordered solid structure, but not for trimethylamine[10], where hydrogen bonding is impossible.

Factorial Analysis of Rheological Measurements on Cheese

In psychology, the meaning of tests of intelligence and mental abilities has been clarified by factorial analyses of the correlation coefficients between the different tests[1]. In industrial physics there are occasions when empirical tests are employed the exact meaning of which is not fully understood, and where the interrelationships between the tests could profitably be studied by similar means. Subjective judgments of quality as assessed by experts and others may be included. In view of the elusive nature of such subjective judgments in cheese-grading, it has been thought desirable to develop a number of related mechanical measurements.

We have carried out an analysis of six separate mechanical tests directed towards measuring essentially different 'properties' on some 250 Cheddar cheese. The tests were as follows: (1) total penetration of a sphere under standard load into the surface after 30 sec.; (2) percentage of this penetration remaining unrecovered 30 sec. after removing the load; (3) penetration of a cylindrical borer under standard load after 10 sec.; (4) ratio of the 10-sec. reading to the 60-sec. reading of the borer (taken negatively); (5) total penetration of a sphere following a series of increments of load (Meyer analysis); (6) slope of the log deformation/log load curve derived from test 5.

The 58 measurements which were correlated were the means from four samples taken from the same batch of cheese. The correlation matrices from these tests were analysed by Thurstone's Simplified Centroid Method[2] without adjustments to the entries in the diagonal cells in the second stage of approximation. The 'factor axes' may, if desired, be rotated according to specified rules; but in the present analysis of data from experiments not specifically designed for a factorial study, little appeared to be gained by rotation. The correlation and factor matrices are given in the accompanying table.

Correlation matrix: ripe cheese

Test	1	2	3	4	5	6
1	....					
2	0·559	....				
3	0·853	0·674	....			
4	0·636	0·255	0·538	....		
5	0·850	0·544	0·765	0·556	....	
6	0·583	0·094	0·434	0·525	0·390	....

Factor matrix

	Factor		
Test	I	II	III
1	+ 0·957	+ 0·026	− 0·026
2	+ 0·602	− 0·499	+ 0·116
3	+ 0·907	− 0·210	+ 0·164
4	+ 0·677	+ 0·301	− 0·083
5	+ 0·861	− 0·123	− 0·297
6	+ 0·574	+ 0·525	+ 0·101

An analysis of the pattern of factor loadings in relation to the qualitative nature of the tests suggests that factors I, II and III may be termed 'hardness', 'springiness' and 'hardening' respectively. It cannot at present be stated how complex these individual 'factors' are or whether, when additional tests are included, further categories will be necessary. The present analysis agrees with Burt's description of factors as "principles of classification"[3].

It is of interest to note that both the borer test and the ball compressor test, each of which has a high saturation with the first 'factor', have been designed to simulate the actions of the skilled grader, the first when plunging a steel skewer into the cheese and the second when 'thumbing' it[4]. By means of these operations, the grader is able to make useful judgments of the rheological properties of unripe cheese, from which he foretells the development of quality.

We conclude from this preliminary survey that the technique of factorial analysis shows promise of giving valuable information where mechanical properties of complex materials are to be compared and studied.

LEAD ISOTOPES AND THE AGE OF THE EARTH

By PROF. HAROLD JEFFREYS, F.R.S.

RATIOS of the abundances of isotopes of lead from a considerable number of ores have been given by A. O. Nier[1] and discussed by A. Holmes[2]. They are expressed as numbers of atoms of Pb^{206}, Pb^{207}, Pb^{208} per atom of Pb^{204}. The last is not of radioactive origin; the others are presumably partly original and partly derived from the decay of the radioactive elements U^{238}, U^{235} and Th^{232}. Their abundance would therefore be expected to increase with time, and this is found to be the case; they are more abundant, always relative to Pb^{204}, in ores more recently formed than in old ones. Holmes has used the variation to derive an estimate of the age of the earth, which he gives as about 3,350 million years. This is substantially more than had previously appeared probable, though no evidence definitely contradicts it. On the other hand, several geophysicists have found Holmes's argument difficult to follow; the following account is partly based on a suggestion made privately by Bullard.

We assume that in a region sampled by the extraction of a lead ore from the rocks within it the atomic abundances of U^{238}, U^{235} and Th are u_m, v_m, w_m; then if the age of the crust is t_0 and the decay constants k_1, k_2, k_3, the original abundances were $u_me^{k_1t_0}$, $v_me^{k_2t_0}$, $w_me^{k_3t_0}$. If the actual sample is of age t_m, the amounts surviving when the ore was formed were $u_me^{k_1t_m}$ and so on. The losses would be associated with the production of equal numbers of atoms of the corresponding lead isotopes. If the original abundances of the lead isotopes were a, b, c, the abundances in the ores will be x_m, y_m, z_m, where

$$x_m = a + u_m\,(e^{k_1t_0} - e^{k_1t_m}) \qquad (1)$$

with similar relations.

If u_m was constant, equations of this type could lead to no estimate of t_0. By a statistical study we could find the variation of x_m with t_m and hence estimate u_m; but any change in t_0 would produce a change of the right-hand side that could be exactly compensated by a change of a, which is one of the unknowns of the problem. The method would fail if the radioactive elements were uniformly distributed through the crust. But if u_m is variable, there will be variations of x_m even for materials of the same age, and this variation will decrease with increasing age, vanishing for $t_m = t_0$. Hence by study of the scatter of x_m for collections of rocks of different ages, it should be possible to find t_0. Holmes proceeds by taking the ore analyses in sets of four, each of which gives one estimate of t_0, and plots the results on a frequency diagram; but this procedure has two disadvantages. It obscures the essential principle that what matters is the variation with time of the scatter of the data; and it suggests also that the evidence is more abundant than it really is. Holmes determines 1,419 solutions by taking sets of four; but the original data refer to only twenty-five rock samples, so that the same material has been used many times.

The constancy of a, b, c is assumed. Correspondingly we may assume constancy, for a given date, of the ratio u_m/v_m. At present this is 139; but as U^{235} decays more rapidly than U^{238}, the ratio was smaller in the past. I shall give two solutions, one without this assumption and one with it.

Study of the radioactive content of rocks has shown that within a given region the abundance of the radioactive elements follows a Pearson Type III law with terminus at zero; but the formation of the maximum likelihood equations with this law proved to be very complicated in the present problem, and as the data refer to many parts of the world the values of the index for specimens from special regions would not be applicable. The normal law of error will therefore be used.

Of the data quoted by Holmes, two (Nos. 20 and 24) are for ores of unknown age. Three (Nos. 9, 10, 11) are for ores from Joplin, Missouri. In other cases where different specimens from the same place have been analysed, mean values are given, and there seems to be no reason against doing the same for the Joplin leads. The data to be used here are then as follows. Holmes's numbering is retained.

No.	Pb^{206}	Pb^{207}	Pb^{208}	Age (m.y.)	Residuals		
1	18·85	15·66	38·63	25	+0·06	+0·03	+0·16
2	18·67	15·45	38·15	25	−0·12	−0·18	−0·32
3	18·40	15·53	38·1	25	−0·39	−0·10	−0·37
4	19·22	16·17	39·15	25	+0·43	+0·54	+0·68
5	18·07	15·40	38·0	25	−0·72	−0·23	−0·47
6	18·71	15·70	38·5	25	−0·08	+0·07	+0·03
7	19·30	15·73	39·5	60	+0·51	+0·10	+1·03
8	16·04	15·11	35·26	60	−2·75	−0·52	−3·21
9, 10, 11	21·89	15·92	40·93	100	+3·10	+0·29	+2·40
12	17·75	16·21	38·05	175	−0·29	+0·56	+0·1
13	18·10	15·57	37·85	220	+0·06	−0·08	−0·1
14	18·20	15·46	37·7	220	+0·16	−0·19	−0·2
15	17·36	15·46	37·38	220	−0·68	−0·19	−0·5
16	18·46	15·66	38·6	220	+0·42	+0·01	+0·6
17	17·95	15·57	37·9	220	−0·09	−0·08	−0·0
18	18·43	15·61	38·2	220	+0·39	−0·04	+0·2
19	14·65	14·65	34·48	600	−0·81	−0·25	−0·5
21	16·27	15·16	35·60	800	+0·81	+0·26	+0·5
22	16·07	15·40	35·5	1200	+0·09	+0·07	+0·1
23	15·93	15·29	35·25	1200	−0·05	−0·04	−0·1
25	15·93	15·30	35·3	1330	−0·05	−0·03	−0·0

The ages fall into four groups, for which the summaries are as follows:

Mean age	Pb^{206}		Pb^{207}		Pb^{208}		Numbe
	Mean	s_1	Mean	s_2	Mean	s_3	
41	18·79	1·52	15·63	0·30	38·47	1·52	9
214	18·04	0·39	15·65	0·26	37·95	0·38	7
700	15·46	1·15	14·90	0·36	35·04	0·79	2
1243	15·98	0·081	15·33	0·061	35·35	0·132	3

The residuals are given in detail, as it will b necessary to refer to them again. s is the standar deviation of one observation, found from the usua formula.

There is a clear trend in the means, a less clea one in the standard deviations s. The estimate o t_0, as we have seen, will depend wholly on the latte Now if the standard error of u_m is σ_1, that of x_m i $\sigma_1(e^{k_1t_0} - e^{k_1t_m})$, and s_1 is an estimate of this. A the standard error of s_1 itself can be taken a $s_1/\sqrt{\{2(n-1)\}}$, it is convenient to write the equation of condition in the form

$$\log \sigma_1 + \log(e^{k_1t_0} - e^{k_1t_m}) = \log s_1 \pm \frac{1}{\sqrt{\{2(n-1)\}}}. \qquad (2$$

For each t_m we have such an equation, and σ_1 i independent of t_m. The equations can be solved b the method of least squares. The solutions are a follows. The last expression in each case has a uncertainty independent of that of t_0: $\beta = (t_0 -$ 1,600 m.y.)/100 m.y.

$$\left.\begin{array}{lll} Pb^{206}.\ \log \sigma_1 = +1{\cdot}54 \pm 0{\cdot}26; & t_0 = 1{,}250 \pm 170 \text{ m.y.}; & \log \sigma_1 + 0{\cdot}113\,\beta = 1{\cdot}14 \pm 0{\cdot}17 \\ Pb^{207}.\ \log \sigma_2 = -2{\cdot}25 \pm 0{\cdot}33; & t_0 = 1{,}390 \pm 170 \text{ m.y.}; & \log \sigma_2 + 0{\cdot}162\,\beta = -2{\cdot}59 \pm 0{\cdot}17 \\ Pb^{208}.\ \log \sigma_3 = +2{\cdot}54 \pm 0{\cdot}26; & t_0 = 1{,}430 \pm 180 \text{ m.y.}; & \log \sigma_3 + 0{\cdot}108\,\beta = 2{\cdot}36 \pm 0{\cdot}17 \end{array}\right\}. \qquad ($$

We compare these solutions with the separate values of s that they were derived from; using the standard errors suggested by (2) we get respectively $\chi^2 = 11\cdot9$, $0\cdot9$ and $11\cdot3$, in each case on two degrees of freedom. Plainly there is some source of variation besides those contemplated in the hypotheses. Also as the estimates of t_0 are not much more than the age of the oldest ore, the probability distributions of t_0 must be very unsymmetrical.

In addition, we have from direct measurement of the isotopic abundances of U^{238} and U^{235}

$$\log\sigma_1 - \log\sigma_2 = 4\cdot93. \qquad (4)$$

We take the last two equations for each of Pb^{206} and Pb^{207}, use (4) to eliminate σ_2, and get a least squares solution

$$s = -1\cdot1 \pm 1\cdot2\,;\ t_0 = 1{,}480 \pm 120\text{ m.y.}\,;\ \log\sigma_1 = 1\cdot89 \pm 0\cdot21. \qquad (5)$$

Comparing this with the four equations used, we get $\chi^2 = 28\cdot7$ on two degrees of freedom. Thus we have a still more serious discordance.

None of the solutions is anywhere near that given by Holmes; and in any case it will be necessary to truncate the probability distribution found for t_0, because the most probable values on these data alone are less than the ages of some known rocks. The following procedure, however, is of some interest. If we take $\sigma_1/\sigma_2 = 139$ as before, the ratio of the present amounts of Pb^{206} and Pb^{207} of radioactive origin should be

$$139\,(e^{k_1 t_0} - 1)/(e^{k_2 t_0} - 1). \qquad (6)$$

For $t_m = 41$ m.y., the ratio should not differ appreciably from this; and the ratio of the values of s_1, s_2 gives

$$\log s_1 - \log s_2 = \log 5 \pm \frac{1}{2\sqrt{2}}. \qquad (7)$$

This expression, equated to (6), gives an equation for t_0, and the solution is

$$t_0 = 4{,}000 \pm 370\text{ m.y.} \qquad (8)$$

This is comparable with Holmes's estimate.

This result, though based on only a portion of the data, indicates the source of the principal discrepancy. When three separate solutions give values in the neighbourhood of 1,400 m.y., a piece of evidence that gives a value differing from this by 2,600 ± 370 m.y. will make a very large contribution to χ^2 however the data are combined. If we accept the smaller values of t_0, or indeed any value less than 3,000 m.y., the variation of Pb^{207} as between ores of the same age is greater than we should expect from the variation of Pb^{206}. On the other hand, if we adopt a value near 4,000 m.y., we have no explanation of the small scatter of the values for the three oldest ores.

The validity of the comparison made in deriving (5) or (8) can be checked from the original residuals. If it is correct that the original ratios of isotopic abundances for the same element were absolutely constant, then for rocks of the same age there should be a strictly linear relation between those of Pb^{206} and Pb^{207}. There are too few determinations in the two oldest groups, but for the two more recent groups we find the following correlation coefficients:

$t_m = 41$ m.y. Pb^{206} and Pb^{207}, $+\,0\cdot77$; Pb^{206} and Pb^{208}, $+\,0\cdot94$.
$t_m = 214$ m.y. Pb^{206} and Pb^{207}, $-\,0\cdot11$; Pb^{206} and Pb^{208}, $+\,0\cdot77$.

On the hypothesis considered, the correlations between the two lighter isotopes should be $+\,1\cdot0$. Actually it appears that the variation of Pb^{206} accounts in the first set for little more than half the variance of Pb^{207}, in the second for none of it. The correlations of Pb^{206} with Pb^{208} in both cases are higher than with Pb^{207}. The two largest residuals, numerically, for Pb^{206} are for ores No. 8 and Nos. 9, 10, 11, and are associated with Pb^{207} residuals of the same sign; but the larger Pb^{207} residual for No. 4 is associated with a much smaller Pb^{206} one. Evidently there is a disturbance affecting the values for Pb^{207} by $\pm\,0\cdot2$ or so and not associated with the variation of Pb^{206}. This could be due to a variation of the order of 1 per cent in the isotopic constitution of the primitive lead, or to experimental errors of the same order in the estimates of Pb^{204}. But in any case the existence of such a disturbance, whatever its explanation may be, shows that no reliance can be placed on the estimates of t_0 that depend on the abundance of Pb^{207}.

On the other hand, each of the values found from Pb^{206} and Pb^{208} gives a χ^2 about six times its expectation, and the adopted uncertainty taken from the normal law of error is much too low. If we simply redetermine it from the residuals, we must multiply it by about $2\cdot4$. The determinations are not independent, since we have seen that the variations within the groups are closely correlated; the best we can do is simply to average the solutions as they stand and increase the estimated uncertainty. The solution is then

$$t_0 = 1{,}340 \pm 420\text{ m.y.}$$

Ahrens[3] gives 2,100 m.y. for the ages of the oldest known rocks. This would suggest that the small scatter in the oldest group of ores in the present study is an accidental agreement. As there are only three in this group, this is quite probable. But so far as the present study goes, it suggests that Ahrens's value is not much less than the true age of the crust. To improve the estimate appreciably would require isotopic analyses of at least four times as many old lead ores. The point is that with any statistical treatment of the data there is a great asymmetry of the posterior probability of t_0; corresponding to the possibility that the scatter of the data for the oldest rocks is an over-estimate, there will be a strong concentration of the probability for values between the greatest of these ages and the 'best estimate', but this must be balanced by a long tail on the other side to give the expectation found for the squared error. Additional information such as the discovery of actual rocks of greater ages will then be taken into account by cutting out the part of the probability distribution of t_0 for values less than the ages of these rocks[4].

EFFECTS UPON TUMOURS OF VARIOUS HALOALKYLARYLAMINES

By PROF. ALEXANDER HADDOW,
PROF. G. A. R. KON, F.R.S.
AND
DR. W. C. J. ROSS
Chester Beatty Research Institute, Royal Cancer Hospital, London

IN an extension of work upon the growth-inhibitory and carcinogenic effects of 4-aminostilbene[1], special attention has been devoted to the influence on these properties of varying the basic side-chain. In one series, the compound 4-NN-di(2-chloroethyl) aminostilbene was of interest as containing the chloroethyl groupings characteristic of the nitrogen mustards. Administration of this substance in relatively high dosage (c. 500 mgm./kgm.) to rats bearing the Walker carcinoma, in an orienting type of experiment already described[1], produced an inhibition of tumour-growth considerable in degree but of very brief duration; and pharmacologically the compound appeared, not surprisingly, to be markedly different from the aliphatic chloroethylamines on one hand and the aminostilbenes on the other.

Partly because of the relatively low toxicity of this compound, and partly because published results in this field deal mainly with chloroalkyl derivatives of aliphatic amines, it became of interest to decide in what types of aromatic amine (if any) the NN-di-2-chloroethyl side-chain could still contribute its specific cytotoxic properties: a long series of haloalkylarylamines, a description of some of which is now in press[2], has therefore been examined to this end. From the biological results it is apparent that marked cytotoxic and inhibitory activity, as judged against the growth of various animal tumours, is a feature of the NN-di-2-chloroethyl derivatives of aniline, *o*-, *m*- and *p*-toluidine, *o*- and *p*-anisidine, β-naphthylamine, and *p*-aminobenzoic acid. Less activity was observed for the corresponding derivatives of α-naphthylamine and *p*-aminobenzaldehyde, while no activity was detected (under the conditions employed) for those of 2:4-dinitroaniline and *p*-xenylamine, or for the NNN′N′-tetra-2-chloroethyl derivatives of benzidine, *o*-tolidine or *o*-dianisidine. Certain compounds, for example, NN-di(2-chloroethyl)-*m*-toluidine and NN-di(2-chloroethyl)-β-naphthylamine, showed perceptible advantages in reduced toxicity, and by administration of these in a single intraperitoneal injection of 70–100 mgm./kgm. in solution in arachis oil on the day following implantation with the Walker tumour, it is possible to extend the survival-period considerably, and even to inhibit development of the graft completely in about half the animals. Similar results may also be obtained through administration of such compounds orally.

In such experiments it has been noted that treated tumours may increase in size for a few days before undergoing regression. Regression is, however, less frequent in larger tumours, although prolongation of survival-time can still be demonstrated in animals bearing fully established tumours. While rather less marked results have been obtained in the case of various mouse neoplasms, for example, spontaneous mammary cancer, the Crocker sarcoma 180, the sarcoma *S*37, the Gorer histiocytoma and a transplantable lymphosarcoma, outstanding sensitivity to inhibition is seen in spontaneous and transmitted leukæmia originating in the Furth *AK*1 pure line, and is expressed in much longer survival times (in certain cases of the order of many weeks) than can be achieved by the treatment of the same tumour with urethane.

Work now in progress is aimed at establishing the optimal structural requirements for biological activity and correlating such with chemical reactivity. Inhibitory activity is clearly associated with the haloethyl chain and not with the basic nature of a given substance, since diethylaniline, for example, is wholly inactive. As in the aliphatic series, a prominen feature is dependence for activity upon two haloalky groups; thus the following types are inactive N-2-chloroethyl-N-ethylaniline, NN-di(2-cyanoethyl) aniline, 2-chloroethylphenylsulphide, chloroacetophenone. Substituents in the aromatic ring which reduc the reactivity of the chlorine atoms, as measured by the rate of hydrolysis in aqueous acetone (fo example, *p*-NO_2, *p*-Cl, *p*-CHO and *p*-CO_2Et), als reduce the biological activity. The active NN-di(2 chloroethyl)-*p*-aminobenzoic acid is an interestin case since the reactivity of the chlorine atom, whil low in the free acid, is appreciably higher in th anion which would be formed at physiological *p*H A considerable number of 2-bromo- and 2-iodo homologues has been prepared: replacement of C by Br or I leads in general to active compound which hydrolyse more rapidly than the correspondin chloro derivatives and usually exhibit increase toxicity. Halo-ethylamine derivatives of larger molecules, for example, diphenyl, are less soluble, an substances of this kind may be inactive notwithstanding substantial reactivity of the halogen atom

This feature suggests that a certain concentratio of reactive halogen compound, expressed as 'reactivit of halogen × solubility', must be reached in order t permit biological activity. Such a relation is show in the series NN-di(2-chloroethyl)-*p*-xenylamine (inactive), NN-di(2-bromoethyl)-*p*-xenylamine (active NN-di(2-iodoethyl)-*p*-xenylamine (highly active and NN-di(2-chloroethyl)-*p*-chloroaniline (inactive NN-di(2-bromoethyl)-*p*-chloroaniline (active), whe in both cases increasing reactivity of the halogen ato compensates for decreased solubility. While 3-chloropropyl derivatives are inactive, as might be anticipated from the low reactivity of the halogen atom NN-di(3-iodopropyl)aniline is also inactive, althoug in this case the reactivity of the iodine atoms is a high as that of the chlorine atoms in NN-di(2-chloroethyl)aniline. 2-Chloropropyl derivatives are i general biologically active and tend to show increase toxicity, as would be expected from the high r activity of the halogen: an interesting comparison provided by NN-di(2-chloroethyl)-*p*-chloroanilin (inactive) and NN-di(2-chloro-*n*-propyl)-*p*-chlor aniline (active). The 2-chloropropyl derivativ studied are hydrolysed without change of structu (cf. Ross[3]), and in particular no evidence has be obtained to suggest, nor would the form of t hydrolysis curves lead one to postulate, the formati of an ethyleneimonium ion. The low basicity of t chloroalkylarylamines (for example, for NN-di(chloroethyl)aniline $pK_a = 2 \cdot 2$ in a series measur by Mr. G. C. L. Goss) would possibly account for t non-existence of this intermediate, in contrast wi the higher basicity of the chloroalkylamines (f xample, for methyl di(2-chloroethyl)amine pK_a = 6·1 [4]).

A fuller account, including a description of the cytological effects produced by these compounds in umour tissue and normal organs, the influence of diet upon response, the further correlation of biological activity with chemical and physical characters, and the clinical effects of selected compounds, will be published later jointly with others. The investigation has been supported by generous grants made o the Royal Cancer Hospital by the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the Division of Research Grants of the U.S. Public Health Service, and was conducted during the enure by one of the authors (W. C. J. R.) of a Sir Halley Stewart Fellowship. It is a pleasure to acknowledge the assistance provided by Mr. J. L. Everett in the preparation of some of the compounds described.

OPHTHALMIC OPTICS

ON November 3, the master of the Worshipful Company of Spectacle Makers, Alderman Sir Frank Newson-Smith, opened a two-day optical convention which was held in the Apothecaries' Company's Hall, London, to mark the fiftieth anniversary of the inauguration of the Company's examinations. During this time, 116 examinations have been held and 4,200 diplomas issued, so that at the present time the services of a useful nucleus of trained opticians s available for the administration of the Health Service Act.

The Spectacle Makers' Company is an old City guild with a charter dating from 1629, which with upplementary ordinances gave control over persons practising the craft throughout Great Britain. These powers were at first rigorously applied; but by the end of the nineteenth century had fallen into disuse. A class of ophthalmic optician had been growing which petitioned the Company about 1898 to ssociate itself with the training and examination of opticians. The convention just held affords ample vidence that the Company is very much alive, particularly at the present time, to the encouragement of the sciences of spectacle and visual optics.

Papers presented and discussed were: (1) The Need of Research and the Means of Meeting it (A. J. Philpot); (2) Optical Theory and Ophthalmic Lenses (W. Swaine); (3) Nomography Applied to Optical Calculations (A. G. Bennett); (4) Some Applications of the Slit Lamp (H. C. Binstead); 5) Binocular Vision (Lord Charnwood); (6) Binocular Vision (Dr. W. D. Wright); (7) Routines and Techniques (C. S. Flick); (8) The Causes of Faulty Refraction (Prof. H. Hartridge); (9) The Physical Interpretation of the Spectral Sensitivity Curve of the Eye (Dr. W. S. Stiles). It is expected that these apers will be bound together in a commemorative olume.

It may be that the successful convention just held, coinciding as it does with the emergence of a profession attending to the visual requirements of the ation, marks the start of an era in which opticians will take a greater part in scientific advancement. Mr. Philpot pointed out that ophthalmic optics is concerned with a nicely balanced mixture of fundamental and applied study, visual problems and spectacle production. While small firms may not be able to finance a special research worker, it should be possible to engage the services of a scientific worker who through education, background and experience could serve as an interpreter and liaison officer between his own organisation and the external research field. The possibility of co-operative research was emphasized. On the visual side, it may be advisable for the optical community to provide bursaries for postgraduate research workers and to provide machinery to effect the absorption of such within the community.

Prof. L. C. Martin presided over the session devoted to the discussion of optical theory and lens calculations. Mr. Swaine, from his experience as examiner to the Company, urged the more direct application of basic fundamental theory not only by candidates for the examinations but also by those who had qualified. He pointed out that it is possible to write down immediately formulæ, involving successive addition or multiplication only, which describe most of the more complicated actions of accommodation, convergence and retinal image size when the eyes are aided by lenses or instruments. Mr. A. G. Bennett gave a valuable summary of nomographic methods generally and their application to ophthalmic and other lenses. A nomogram to solve the problem of contact lens design was described. Of particular interest was a composite circular and elliptic nomogram—four nomograms on one framework—designed to solve the laborious calculation of prismatic effect at decentred points of astigmatic thin lens systems.

Mr. H. H. Emsley, an examiner to the Company, presided over a session to discuss binocular vision. Lord Charnwood commenced with a review of fusion and suppression theories of stereoscopic vision. With his paper he presented a set of eight stereograms with which self-experimentation could be made in order to test descriptions and deductions which a theory of stereopsis must explain. Some of these are: single binocular vision can obtain provided retinal disparity is not too great, when it will be seen that the images glide into fusion; fusion of disparate images is more difficult if disparity is such as to contradict other clues. Suppression of stereopsis can occur without suppression of images, and occurs when the stereopsis runs counter to preconceived convictions—such suppression causes discomfort. The role of the mind in choosing an interpretation which fits best the other evidence, changing from one interpretation to another at will, was emphasized. An explanation was suggested whereby stereopsis is attained by a process of integration of successive disparities too small to cause physiological diplopia.

Dr. W. D. Wright took up an intentionally provocative thesis criticizing the theory that stereopsis arises from retinal disparity. The rapid drop of visual acuity with distance from the fovea suggests that the peripheral parts of the retina contribute little to stereoscopy from disparate points. It does impart to the eyes a pointer-like action ('visual fingers') by the foveæ which, combined with an elementary foveal fusion and with the assistance of the muscle movements, through mental integration, serves to complete the solidity impression.

Mr. H. C. Binstead showed the development of the slit lamp from Gullstrand through Fincham's design to its applications for the examination of the iridic angle, depth of the anterior chamber, depth of lesions in the eye media and the ingenious Ronne colloidometer for measuring the albumen content of the aqueous. Mr. C. S. Flick set the question: Do routines and techniques for the measurement of refractive error matter? A set of four typical routines included one which was typically American —a twenty-one point technique with standardized analysis—which led to extensive discussion.

Prof. H. Hartridge provided a fascinating introductory study of the development of X-ray techniques for determining the actual length of the living eye (Rushton, Sorsby and O'Connor) and the Goldmann–Hagen modification for measuring refraction. This led to the development of the main topic of his lecture, the cause of refractive error. Five or six theories were passed under review to explain the normal tendency of eyes so commonly hypermetropic at birth to settle down to an approximate emmetropic condition. The X-ray technique should serve to separate the roles of axial length and of optical refraction, which hitherto was not possible.

Dr. W. S. Stiles reviewed the physics of light absorption (including finer adjustments introduced by quantum considerations) and the bleaching of visual purple. Three curves of corrected means effected a simultaneous comparison of absorption coefficients and photosensitivity of visual purple solutions and the subjective spectral sensitivity of the dark-adapted parafoveal retina. The maxima at 500 mμ all agreed; but further study is needed in order to explain the differences towards the violet side, where there appears an absorption band at about 360 mμ. The curves agree very well on the red side of the maximum, especially as regards linearity and gradient, for which a rough theory giving a good fit of gradient was elaborated. A comparison of spectral sensitivity curves of the parafoveal rod vision and of the foveal cone vision shows, besides the Purkinje shift, a significant gradient difference on the red side of the maximum. This will require explanation in any future photochemical theory of vision.

WILLIAM SWAINE

ELASTICITY OF WOOD AND PLYWOOD

SPECIAL REPORT No. 7, issued by the Forest Products Research Laboratory (London: H.M. Stationery Office, 1948. 2*s.* net), summarizes the available information on a piece of important research undertaken on the "Elasticity of Wood and Plywood". The work and results embodied in the report are said to be mainly for the designer and the research worker. The forest officer might also have been included, since on the work of the sylviculturist all 'wood' of the future, whatsoever its type, may be said to depend, with the exhaustion of Nature's resources.

The theory of wood elasticity rests on the assumption that the gross material possesses three perpendicular planes of elastic symmetry, and that it is perfectly elastic and homogeneous. A point which needs emphasis at the outset is that wood is actually only an approximation to this ideal material. The longitudinal tangential surface (the surface generated by a line parallel to the axis of the tree and moving along the growth rings) is not plane, but roughly cylindrical. The other two principal surfaces, the longitudinal-radial (defined by the axis of the tree and the medullary rays) and the tangential-radial, are more truly plane; but even in these cases there will be some deviation owing to local irregularities in the growth of the tree. This is where the sylviculturist comes in. "The extent to which any actual specimen departs from the ideal material will depend not only on the regularity of the growth but also on the position of the specimen in the tree."

The report is intended chiefly as a summary of knowledge known, but it contains a number of new results, some obtained in America and Australia during the Second World War, here published for the first time. The first part of the report is entitled the "Elastic Constants of Wood"; it deals with the measurement of the nine independent elastic constants of wood and the effect on them of factors such as temperature, moisture content and grain angle. The second part deals with the elastic constants of plywood. The manner in which they are related to the form of construction of the plywood and to the elastic constants of the wood from which the plywood is made is explained.

Under the heading of "The Properties of Plywood Plates and Cylinders", the third part deals with the frequency of vibration, the buckling and deflexion of plywood plates and the buckling of plywood cylinders

INTERNATIONAL SCIENTIFIC FILM ASSOCIATION

SECOND ANNUAL CONGRESS

THE most important outcome of the annual congress of the International Scientific Film Association held in London during October 4–11 1948, has been the formation of a number of international commissions to pursue in detail the programme of work agreed in general by the member countries for the coming year. Before discussing this programme, a few words on the Association's history may not be out of place.

The International Scientific Film Association was inaugurated last year in Paris, largely as a direct result of the initiative of the British and French Scientific Film Associations. The preliminary work of these two organisations, the first contact of which at the end of the War revealed many common interests, resulted in the assembly last year of representatives from twenty-two countries to discuss and agree to the formation of this international organisation to further the interests of the scientific film. Unesco, recognizing the scientific film as an important aid in the dissemination of knowledge, showed a benevolent interest in the new Association, the maintenance of which was demonstrated by the attendance again of a Unesco observer at this year's Congress.

Some twenty-five countries had accepted the invitation to the second Congress, and the number of those who finally managed to send delegates fell little short of this figure, some unfortunately failing to overcome the many obstacles with which post-war travelling is beset.

The honour of organising this year's congress was given to Great Britain, and its Scientific Film Association, assisted by financial aid from the British Film Institute, rose worthily to the occasion. A ver full programme of eight days of meetings, receptions, demonstrations and film showings was arranged and carried through smoothly.

The general assemblies of the delegates formed the most important part of the proceedings. The events of the first year of the Association's history were reviewed, and delegates gave brief reports of the work being done in their countries. It was striking testimony to the value of the activities of the Scientific Film Association of Great Britain to note how several countries, notably Holland and Belgium, are modelling their own young organisations along closely similar lines.

The need for continuous exchange of general information, and details regarding films in particular, soon established itself as paramount in the discussions. A vital step in its fulfilment was taken by the approval of an index card to record essential data of scientific films and thus to form the material for the first catalogue of such films available throughout the world. One of the international commissions set up was charged with supervising this work and preparing recommendations for the international appraisal and grading, according to merit and purpose, of scientific films.

Other matters of prime interest in the further work of the Association were also entrusted to commissions. It is believed that these will be able to work out practical details for some kind of international co-operation in the joint production of certain specialized films, and that eventually the problem of film distribution on the widest international scale will be solved. Discussion indicated to what extent customs barriers and finance regulations are likely to hinder the early achievement of this aim, but hope for a solution, even if only on a limited scale at present, was not abandoned.

The Belgian delegate offered a very practical contribution by trying to form an international scientific film reference library in his country. The representative of the Dominican Republic suggested that they might help by providing translations of information for the Spanish-speaking countries. Such offers of practical assistance showed the keen interest in the proposed activities and pervaded the meetings with a strong feeling that the aims of this international organisation are likely to be successfully implemented.

Much of the proceedings of the assemblies was in connexion with the constitution and internal organisation of the Association itself. While these may not be of such immediate public appeal as other matters already mentioned, they are none the less essential for the smooth and efficient working of the Association. In accordance with its democratic constitution, delegates from member countries elected a governing Council for the coming year, the officers of which are: *President:* M. Jean Korngold (Poland); *Vice-Presidents:* Mr. John Maddison (Great Britain) and Mr. C. A. Burmester (Australia); *Honorary Secretary:* M. Jean Painlevé (France); *Honorary Treasurer:* M. Luc Haesaerts (Belgium).

In conclusion, mention should be made of some of the many events occupying the full programme of the week. Receptions for the delegates were given by the Council and Congress Committee of the Scientific Film Association of Great Britain, the Royal Microscopical Society and the British Council. At the former, the inaugural reception, delegates were received by the Parliamentary Under-Secretary of State for Commonwealth Relations on behalf of the Lord President of the Council. These various functions, while dignified, were given a pleasantly informal character by the renewing of many old friendships among the delegates.

The Scientific Film Association of Great Britain had also organised some specialists' meetings dealing with the film in medicine, schools, universities, industry and scientific research. They provided welcome opportunities for discussion between experts in Britain and abroad as to how best the film can help in these various fields. Much valuable material was contributed from both sides and the detailed discussions served to co-ordinate thought on these problems. These links between groups of similar specialized interests, thus established, will serve to strengthen considerably the work of the International Association.

Fifteen of the participating countries sent more than sixty scientific films, some of which were shown during the course of these specialized meetings, but about forty of which formed the programme for a public International Scientific Film Festival held in London on October 8, 9 and 10. Such was the interest in this Festival that the hall of the Royal Empire Society was filled to capacity by some four hundred spectators on six separate occasions. An even wider audience, estimated at 100,000, was reached, however, by means of television. On October 4, a special programme was transmitted giving previews of some of the films to be shown later and ending with the first demonstration in Britain by the French delegate, M. Jean Painlevé, of the combination of television camera and microscope to achieve 'live' broadcast pictures of microscopic organisms.

The second congress of the International Scientific Film Association in London will undoubtedly be remembered as a significant milestone in the history of the Association. One may hope, however, that it served an even wider purpose, for it demonstrated once again the common aim of all men of science to further human progress and happiness. To achieve this on a truly world-wide scale, the film will play a major part by using visual images to transcend barriers of language in the spreading of knowledge.

MICHAEL MICHAELIS

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Saturday, November 20

ROYAL AERONAUTICAL SOCIETY (joint meeting with the HELICOPTER ASSOCIATION, at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 11 a.m.—Discussion on "Helicopters".

Monday, November 22

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Single-Phase to Three-Phase Conversion Systems" (to be opened by Mr. A. N. D. Kerr).

UNIVERSITY OF LONDON (at the Institute of Education, Malet Street, London, W.C.1), at 5.30 p.m.—Mr. H. E. Bowman: "Education for International Understanding—The Moslem World".*

INSTITUTION OF THE RUBBER INDUSTRY, MANCHESTER AND DISTRICT SECTION (at the Engineers' Club, Albert Square, Manchester), at 6.15 p.m.—Dr. W. McG. Morgan: "Accelerators for Stocks containing Reinforcing Furnace Blacks".

TEXTILE INSTITUTE, YORKSHIRE SECTION (in the Large Hall, Technical College, Huddersfield), at 7.15 p.m.—Mr. B. H. Wilsdon: "Principles of Textile Research".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.C.2), at 8 p.m.—Mr. L. H. Bedford: "Some Technical Aspects of Television" (Cantor Lecture).

Tuesday, November 23

UNIVERSITY COLLEGE, LONDON (in the Anatomy Theatre, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. F. W. Jane: "Some Problems in being a Tree".*

Chadwick Public Lecture (at the Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Mr. Alister MacDonald: "The Influence of Hygiene on the Shape of Buildings" (Bossom Gift Lecture).*

Royal Anthropological Institute (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. Robert H. Lowie: "Some Aspects of Political Organisation among the American Aborigines" (Huxley Memorial Lecture).

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. J. E. Rhys-Jones: "Printed Circuits, including Miniature Components and Sub-Miniature Valves".

Sir Halley Stewart Trust Lecture (at the Memorial Hall, Farringdon Street, London, E.C.4), at 6 p.m.—Lord Russell, F.R.S.: "The Atomic Age—Our Scale of Values in the Atomic Age".*

Society of Dyers and Colourists, Scottish Section (at the St. Enoch Hotel, Glasgow), at 7 p.m.—Dr. D. Traill: "The Problem of the Synthetic Fibre".

Wednesday, November 24

Institute of Fuel, North-Western Section (at the Engineers' Club, Albert Square, Manchester), at 2 p.m.—Mr. J. E. O'Breen: "Automatic Control of Steam Raising Plant".

University of London (at Bedford College for Women, Regent's Park, London, N.W.1), at 5.15 p.m.—Prof. L. J. Audus: "Jungle Economy" (Inaugural Lecture).*

Linnean Society of London (in conjunction with the Systematics Association, at Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. T. A. Sprague: "Botanical Taxonomy up to and including Linnæus".

Manchester Literary and Philosophical Society, Chemical Section (at the Portico Library, 57 Mosley Street, Manchester), at 5.30 p.m.—Dr. Metcalfe Brown: "Chemistry and Public Health".*

Society of Chemical Industry, Microbiological Panel of the Food Group (in No. 3 Room, Gas Industries House, Grosvenor Place, London, S.W.1), at 6.15 p.m.—Dr. J. B. Firth: "Spontaneous Combustion in Hay, Cotton and other Vegetable Materials".

Thursday, November 25

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Discussion on "The Theory and Practice of New Techniques in Separation and Purification".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Physical Society, Acoustics Group (in the Small Physics Theatre, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 5 p.m.—Mr. R. S. Dadson and Mr. E. G. Butcher: "Apparatus for Acoustical Measurements at Low Frequencies".

Physical Society, Low-Temperature Group (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 5.30 p.m.—Prof. C. J. Gorter (Leyden): "Irreversible Processes in Liquid Helium II".

Institute of Welding (joint meeting with the Institution of Structural Engineers, at 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—Dr. H. Gottfeldt: "Curved Bridges and Why they should be Welded".

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. W. H. Lindsey: "Development of the Armstrong Siddeley Mamba Engine".

Institute of Metals, Birmingham Section (at the James Watt Memorial Institute, Great Charles Street, Birmingham), at 6.30 p.m.—Mr. T. Land: "High Temperature Measurements".

Royal Institute of Chemistry (at the Medway Technical College, Gardiner Street, Gillingham), at 7.15 p.m.—Dr. F. Wormell: "The Corrosion of Metals".

Society of Dyers and Colourists, West Riding Section (at the Great Northern Victoria Hotel, Bradford), at 7.15 p.m.—Dr. E. A. Krahenbuhl: "New Principles in the Continuous Dyeing of Wool".

Wednesday, November 24—Thursday, November 25

Institution of Gas Engineers (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 10 a.m. each day. —Fourteenth Autumn Research Meeting.

Friday, November 26

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Geophysical Discussion.

Royal Statistical Society, Birmingham Group of the Industrial Applications Section (in the Chamber of Commerce, 95 New Street, Birmingham), at 6.30 p.m.—Mr. Philip Lyle: "Factorial Regression Analysis".

Manchester Statistical Society, Industrial Group (at the Society of Architects, 16 St. Mary's Parsonage, Manchester), at 6.45 p.m.—Mr. W. T. Hale: "The Statistical Solution of an Industrial Problem".

Institute of Physics, Manchester and District Branch (in the New Physics Theatre, The University, Manchester), at 7 p.m.—Dr. A. B. D. Cassie: "Physics in the Wool Industry".

Institution of Electronics, North-Western Branch (at the Gas Showrooms, Town Hall, Manchester), at 7 p.m.—Mr. P. A. Cummins: "Electronic Equipment for Radio Control".

Royal Photographic Society, Scientific and Technical Group (joint meeting with the Industrial Radiology Group of the Institute of Physics, at 16 Princes Gate, London, S.W.7), at 7 p.m.—Mr. H. S. Tasker and Mr. K. H. Gaseltine: "The Reproduction of Radiographs".

Society of Chemical Industry, Fine Chemicals Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 7 p.m.—Dr. F. Bergel: "Some Aspects of the Relationship between Chemical Constitution and Physiological Activity".

Saturday, November 27

British Psychological Society, Social Psychology Section (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 8 p.m.—Prof. T. H. Pear: "Social Stratification as a Necessary Consideration in English Social Research".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Graduates in Chemistry (2) as Research Assistants in the Department of Chemical Engineering and Applied Physical Chemistry—The Registrar, Imperial College of Science and Technology, South Kensington, London, S.W.7 (November 27).

Lecturer (Grade IIb) and a Lecturer (Grade IIc) in the Department of Electrical Engineering—The Secretary, The University, Edmund Street, Birmingham 1 (November 27).

Scientific Editor in London (Central Office of Information) for news and feature periodicals published in Eastern Europe—The Ministry of Labour and National Service, Technical and Scientific Register K, York House, Kingsway, London, W.C.2, quoting A.374/48A (November 30).

Mining Consultant to advise the Government of Tanganyika on all matters pertaining to mining development in that territory—The Ministry of Labour and National Service, Technical and Scientific Register K, York House, Kingsway, London, W.C.2, quoting C.731/48A (November 30).

Technician in the Pathology and Bacteriology Laboratory at Galway Central Hospital—The Secretary, Galway County Council, County Buildings, Galway (December 7).

Chair of Physical Geography at Fouad I University—The Dean of the Faculty of Arts, Giza, Egypt (December 15).

Lecturer in Physiology in the United College—The Secretary, The University, St. Andrews (December 15).

City and Water Engineer to the City of Port Elizabeth, South Africa—Davis and Soper, Ltd., 52–54 St. Mary Axe, London, E.C.3 (December 31).

Marine Zoologists (2)—The Secretary, Marine Biological Association, The Laboratory, Citadel Hill, Plymouth (January 31).

Biochemist or Organic Chemist in the Department of Lactational Physiology, to assist in the investigations of the intermediary metabolism of the mammary gland—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, Berks.

Telecommunication Engineers in the Postmaster-General's Department, Commonwealth of Australia—The Representative of the Australian Post Office, Australia House, Strand, London, W.C.2, endorsed 'Application for position of Telecommunication Engineer'.

Graduates in Physics or Chemistry for investigation of various problems connected with the manufacture of pottery—The Director, British Ceramic Research Association, Queen's Road, Penkhull, Stoke-on-Trent.

Entomologist in the Medical Department (Health Branch) of the Gold Coast—The Director of Recruitment, Colonial Service, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Lecturer in Agricultural Zoology, and an Assistant Lecturer in Agricultural Botany—The Secretary and Bursar, Seale-Hayne Agricultural College, Newton Abbot, Devon.

Departmental Demonstrator in Physical Anthropology—The Professor, Department of Human Anatomy, The University, Oxford.

Physicist for fundamental work on the structure and properties of fibrous materials, etc., and a Physicist for laboratory and service test of shoes and shoe materials, etc.—The Director, British Boot, Shoe and Allied Trades Research Association, Satra House, Rockingham Road, Kettering.

Metallographer with wide experience of non-ferrous metals and alloys, to take charge of metallographic laboratory—The Secretary, British Non-Ferrous Metals Research Association, 81–91 Euston Street, London, N.W.1.

Laboratory Steward (Grade I) to take charge in Department of Geography—The Registrar, University College, Leicester.

Biochemist (man or woman, preferably with post-graduate experience in the field of Enzymes or Tissue-Metabolism) for research appointment—The Secretary, Courtauld Institute of Biochemistry, Middlesex Hospital Medical School, London, W.1.

Technical Officers and Senior Technical Officers for work in connexion with the pottery industry—The Director, British Ceramic Research Association, Queen's Road, Penkhull, Stoke-on-Trent.

Curator—The Honorary Secretary, Hancock Museum, Newcastle-upon-Tyne 2.

Lecturer in Zoology—The Registrar, University College, Exeter.

Agricultural Research Officer, Cyprus—The Director of Recruitment (Colonial Service), Colonial Office, 2 Sanctuary Buildings, Great Smith Street, London, S.W.1.

DISTRIBUTION OF INDUSTRY IN BRITAIN

CRITICISM of the Distribution of Industry Bill of the Coalition Government of 1945 centred mainly on the two points: whether the Government had a central policy in regard to the location of industry, with all that such a policy implies in regard to the control of the use of land, town and country planning, agriculture, building and amenities; and whether the Board of Trade was, or would be, staffed with the type of Civil servant qualified by training, outlook and experience to deal with these positive functions of government with imagination, decision and courage. No central independent tribunal had then been established to consider the national position as a whole, as recommended in the report of the Barlow Commission, nor has the present Government taken such action.

The paper on "Distribution in Industry" just issued by the Board of Trade* once again indicates the seriousness of the omission. The immediate occasion for the paper is the duty placed by the Act on the Board of Trade jointly with the Secretary of State for Scotland of reviewing the boundaries of the Development Areas from the passing of the Act. The paper examines in some detail the results which have followed, partly from war-time developments, and partly from the operation of the policy adopted, not only in the Development Areas, as the old Special Areas have been designated, where they are most apparent, but also in the rest of Great Britain. On the negative side, the Government has restricted new industrial development in parts which were already congested with industry; and on the positive side, it has, with the co-operation of many industrialists, assisted the Development Areas and other parts which needed more industrial employment.

The situation in the Development Areas has changed for the better, both absolutely, and relatively to other parts of Britain. Employment in these areas is much greater than before the War, while unemployment is now much smaller; and when the programme of industrial growth at present only half completed is fulfilled, there should no longer be a special danger of heavy localized unemployment in most parts of the Areas. There will be more of the industries which have been less liable to depression than some of the basic industries in which the greatest proportion of workers in those Areas was previously engaged. The existence of a wider range of industries will also mean that a recession in any one of them will have less effect on the economy as a whole. Nevertheless, the White Paper argues that it is too soon to remove the whole or part of any of the present Development Areas from the first schedule of the Act. On the contrary, it recommends the addition of two new Areas: Merseyside, and a district to serve as an industrial nucleus for the Highlands of Scotland.

The policy on the distribution of industry pursued by the Board of Trade has as its purpose the provision of regular work for the greatest possible number of those seeking it in all parts of Great Britain, especially in those parts which are known as the Development Areas, and so helping to raise the number in work and the nation's total output to the highest possible level. Now, although the White Paper admits that sometimes there have been sound economic reasons why movement of particular enterprises to the Development Areas was impracticable, such a purpose, the natural development of the policy evolved in the late thirties, fails to take adequate account of the new situation. What were the 'depressed' industries are now those that most need labour. Furthermore, Britain's economic recovery depends on capital reconstruction and equipment being concentrated in those industries where it will increase exports or save imports.

---

* Distribution in Industry. (Cmd. 7540.) Pp. ii+52. (London: H.M. Stationery Office, 1948.) 1*s*. net.

These are the principles against which we must judge the fact that about half the new factory-building since the War has been in the Development Areas, which have only 2,500,000 of the country's workers. The weakness of the White Paper is that it fails to take account of, and clearly distinguish, the social and the economic aspects of the policy it describes. The White Paper, in fact, is exclusively concerned with the first—the prevention of widespread unemployment—and so much ignores the second that it does not stop to consider whether, measured by the numbers placed in employment, the experiment in directing new industries to the Areas has been very costly. Nor is there shown any awareness that the attraction of a particular enterprise to the Areas may increase the cost of its products. For example, it is probable that location of the British Nylon Spinners, Ltd., mill at Pontypool, instead of at Banbury, may, owing to the double haulage of the polymer and the spun yarn necessitated, involve in effect a small continuing levy on nylon sales.

Under pre-war conditions, it might still have been worth while, from the national point of view, to locate this industry in Monmouthshire. Under post-war conditions and with the present insistence on exports, where costs are becoming increasingly important, particular instances must be judged by the same criteria as the general policy: are resources being directed into the Development Areas which could from the national point of view be better employed elsewhere, and is the movement of labour from those Areas to other districts urgently needing men being prevented? We cannot continue to build factories for unimportant industries while industries where development is essential are unable to get new buildings and equipment. On these issues the White Paper is silent. Nor does it consider the social implications of the present policy of encouraging in those Areas the lighter industries providing consumers' goods. Quite apart from the question of which type of industry should be encouraged from the point of view of economic recovery, the demand for export goods is much more likely to be sustained than that for the consumer goods coming from the light industries.

The dominant impression left by this White Paper is, in fact, the lack of clear thinking. There is no evidence that policy is governed by explicit principles about the distribution of industry. The slightness c the reference to the report of the Barlow Commissio indicates the absence of such a coherent policy, an it would not be unfair to conclude that the influenc of pressure groups has deflected the Board fro paying attention to the essential price that has to b paid for social security—mobility of labour. This i not a matter of directing men and women to th factories rather than, so far as possible, bringing th factories to the workers. Security and enterprise a uneasy bedfellows, but both are essential in an economic system; and enterprise is a quality not t be restricted to the management or employer. It i true that the State must now ensure that there a certain minimum social and economic standard below which no one can fall, in order to forestall th threats of insecurity to the efficiency of its industri and economic life. It is equally true that, unde modern conditions, the workers cannot enjoy th higher standards of living which mechanical advan has put within their reach unless they themselv show enterprise, initiative and adaptability to t changing conditions.

The most hopeful section of this White Pape is that which deals with research for the futur For all its shortcomings, it recognizes that wi conduct of the distribution of industry deman constant study and examination of the needs an resources of every part of Britain, and that the futu of the Development Areas is bound up with that world trade and our share in it, and with that certain basic industries such as coal, steel and shi building. Among the functions which the Barlo Commission recommended that a central authorit should discharge was the organisation of researc and it was recognized that to provide a sure basis f action under the Development of Industry Act it w essential that the Government should establish research organisation capable of studying the ma problems of industrial location in greater detail tha had hitherto been possible.

Regional research units have been set up joint by the Board of Trade, the Ministry of Labour a the Ministry of Town and Country Planning, and, Scotland, the Department of Health. This policy decentralization has already borne much fruit; th the plan for the West Midlands region recently pr duced by Sir Patrick Abercrombie and Mr. Herbe Jackson at the behest of Mr. Silkin is one exampl Small research staffs, however, are maintained headquarters to direct and co-ordinate the work the regions, to provide basic data of a natio character and to study particular problems whi can be most effectively studied at the centre. extensive programme of research has been undertak to assist the regional offices of government depa ments concerned in the execution of the distributi of industry. General surveys of all the regions a sub-regions throughout the country have furnish knowledge about such matters as variations in industrial structure of regions and sub-regions a their causes, difference in industrial specialization a diversification, divergences in the degree of vuln ability to structural and localized unemployment between areas, industrial facilities and basic services, the constitution and geographical distribution of industrial population, labour supplies, industrial sites, the availability of factory premises, housing and general amenities.

The administration of the Distribution of Industry Act has revealed some problems requiring special investigations of particular areas or towns, and the possible uses in peace-time of war-time government factories. It is also stated that the development of physical planning, the drive to increase production in the textile and other industries, and the necessity for concentration upon the manufacture of goods to meet the export target, have all led to further research; though, as already indicated, the White Paper does not elsewhere indicate much awareness on the part of the Board of Trade of this point where the Development Areas are concerned. In addition to the maintenance of comprehensive records of what has been done or is planned, the fullest measure of co-operation exists with the research officers of the Ministry of Town and Country Planning, as well as with the staffs of local planning authorities, to ensure that research on distribution of industry problems is properly related to all developments in town and country planning.

Most of the activities described in this section of the White Paper admittedly relate to current issues and short-term problems; and in this account more reference might well have been made to the contributions from other bodies such as the West Midland Group and the Northern Industrial Group. The study of long-term problems, however, has also been undertaken, and here it is recognized that there are certain fundamental problems which are best investigated by the universities. To ensure that these problems will receive attention, the Board of Trade set up early in 1947 an informal committee, with Sir Henry Clay as chairman, consisting of members of the economic and statistical departments of several universities, to consider how the assistance of the universities might be secured.

This account of the research activities of the Board of Trade in the field of the location of industry, set against the general trend of the whole report, conveys the main impression that failure to implement the proposals of the Barlow Commission has been due to ineffective co-ordination, duplication of effort and the absence of any authority competent to choose the right subjects of research and ensure that the results of research are used. Unified research into the problem of distribution on a national scale is embryonic; there is no unified plan of development based on such research, and no effective control meanwhile of such changes as must continue to take place in the interests of trade. We are no nearer than when the Distribution of Industry Act was passed to the effective relation of schemes for industrial development to those for hydro-electric development, water supply, the building of new towns and the like.

The absence of that high standard of ministerial statesmanship which Gertrude Williams, in her book, "The Price of Social Security", showed to be the essential foundation of successful government control of any communal activity effectively prevents the formulation of a national policy. Piecemeal developments and yielding to sectional interests make the objectives professed in this White Paper as farcical as the continued encroachment on national park areas or Nature reserves by unco-ordinated demands from the Services and other interests make the nominal profession of the Government of supporting the idea of Nature reserves or national parks. This White Paper shows little sign of the imagination, vigour and statesmanship which could reverse these trends, and give Great Britain a genuine national policy for land use in which the claims of defence, amenities, industry and culture are fairly balanced, apportioned and reconciled.

THE LIFE AND WORK OF CHARLES DARWIN

Charles Darwin

Par Jean Rostand. (Collection 'Leurs figures'.) Pp. 244+4 plates. (Paris: Libr. Gallimard, 1947.) 220 francs.

THIS book is easily readable. It deals in a pleasant manner with Darwin not only as a man of science but also as an individual. It mentions, but does not stress, the shocking state of health in which Darwin carried out all his work after he returned from the voyage with the *Beagle*. The fact that, during the years 1837–59, while Darwin was collecting together his material for the "Origin", he carried out and published all the geological results of the *Beagle* expedition and, at the same time, produced a monograph on the barnacles which is still the standard work on this group can only be appreciated when it is remembered that he could only work at his desk for relatively short periods and was continually bound to lie down and rest after these short periods of exertion.

The book, however, cannot be said to throw any new light on Darwin. It is written in the modern Neo-Mendelian idiom. One sentence (p. 144) gives away the author's attitude. He maintains that one of the greatest originalities of Darwin was to have seen in the variation of domestic animals the image of the phenomenon of evolution. To a Neo-Mendelian this may make sense, but, of course, it begs the question. Then, again, the author states definitely that we now know that acquired characters are not inherited. Whatever view one may take as to Lamarck's theory—a theory which, the author rightly points out, was always misunderstood by Darwin—it has certainly never been established scientifically and probably never will be that acquired characters *cannot* be inherited. Surely it is a fact that recently one of our leading Neo-Mendelians published an account of a mechanism based on the conception of the gene complex whereby acquired characters *could* be inherited. They cannot have it both ways!

It is a pity that the author does not stress the fact that in the title of the book "On the Origin of Species" there are two inaccuracies: the word 'origin' should really have been 'establishment' after the species had originated, and then the word 'species' is not defined; and Darwin pointed out in a letter to Hooker "to define a species is to wish to define the indefinable".

H. GRAHAM CANNON

COTTON SEED: A PIONEER CROP AND AN EXAMPLE

Cottonseed and Cottonseed Products

Their Chemistry and Chemical Technology. Edited by Alton E. Bailey. (Fats and Oils, a Series of Monographs on the Chemistry and Technology of Fats, Oils and related Substances.) Pp. xxiii+936. (New York and London: Interscience Publishers, Ltd., 1948.) £5 5*s*.

THE cultivation of cotton in quantity in the United States did not commence until towards the end of the eighteenth century; but the cotton fibres only were utilized for many years, the rest of the cotton seed not being recognized to have any, except perhaps manurial, value. Although so early as about 1830 crushing of the seed was commenced in a small way, it was not until after the American Civil War that the value of the cotton seed was more fully appreciated, and that its conversion into cotton-seed oil and cotton-seed cake was undertaken on an increasingly large scale. From 1910 onwards, however, cotton-seed crushing became one of the major industries in the United States. Frequently, the quantity of cotton seed crushed annually exceeded 5,000,000 tons, the corresponding value of the products (oil and residual cake) usually being more than 200,000,000 dollars. The annual production of cotton-seed oil was 700,000–900,000 tons, and of cotton-seed cake and meal 2,000,000–2,500,000 tons. The cake is valued as an animal feeding-stuff and is also used as a fertilizer, while the oil is used both as salad oil, in margarine and in cooking fats (lard substitute) either in its original state or after 'hardening' by partial hydrogenation, and as one of the raw materials for soap-making.

Thus a by-product of the production of the cotton plant for textile purposes came at length to be the source of a number of other materials of vital importance, notably the contribution of three-quarters of a million tons or more annually of valuable edible fatty oil. The cotton-seed crushing industry was thus a pointer to what is now seen to be an urgent need in overcoming the increasing world shortage of fats, namely, the cultivation of suitable species of oil-seeds primarily for the sake of their oil content and of their residual cake or meal for feeding animal stock. Moreover, the careful selection and cultivation of both seed and crop, which have been practised for many years in order to secure constancy of quality in the cotton fibre, are evidently an example to be followed in the cultivation of other oil-seeds in order that oil and cake of the highest quality may be produced. Oil-seed cultivation is a branch of agriculture with its own special problems demanding specific control in regard to the quality of the products ultimately to be harvested.

The present volume of more than 900 pages, edited by Dr. A. E. Bailey, is thus informative to the British reader not only for its wealth of information on cotton-seed products, but also for the utilization of the knowledge acquired in this industry when dealing with other oil-seeds. The book is remarkable for its scope and for the exhaustive manner in which the details of all phases of the industry have been covered. It consists of twenty-four monographs, each of which has been written by an author with special knowledge of the part of the subject which has been entrusted to him. It opens with two monographs which deal with the history of the cotton-seed industry and its economic development, and here, as elsewhere in the book, the discussion is not restricted to the United States, but also includes full accounts of the smaller but still important cotton industries of India, Egypt and some other countries. The next seven monographs (amounting to 400 pages) deal very fully with the constituents of cotton seed—fatty oil, proteins, pigments, etc.—and also with the influences exerted upon these by differences in variety, maturity and environment of the growing cotton plant, while a separate section is devoted to the biological processes of the cotton seed. Later sections cover equally exhaustively the processing of the seed and of its various products, naturally with special emphasis on the refining, hydrogenation, etc., of cotton-seed oil for use as an edible fat. There is also a useful discussion on the nutritional aspects of cotton-seed oil utilization in the human dietary (which, in fact, covers and includes the corresponding aspects of most other vegetable fatty oils); and the concluding monographs deal with cotton-seed oil for soap, cotton-seed cake as a source of animal food-stuffs, and the utilization of cotton-seed hulls and linters.

The book is outstandingly comprehensive in its exhaustive treatment of all the factors—scientific, technical and economical—connected with the cotton-seed industry. The enormous quantity of factual data of all kinds appears to have been collected with accuracy and is certainly presented lucidly and clearly. Full references to scientific and technical literature are given, with adequate author and subject indexes. The editor and publishers are to be congratulated on the production of so complete a guide to the products of the cotton seed, and to the technical aspects of the important industries which have been built up in connexion with its processing.

As indicated earlier, the volume is of importance and interest to a wider circle than those concerned with cotton seed itself. The principles involved in the cultivation and processing of cotton seed are in many instances equally applicable to other oil-seeds. Notably this applies to consideration of the variety and environment of the plant in relation to the seed fat produced, and to the influence of moisture and enzymes on retrogressive changes within the harvested seed, leading to oxidation and to production of free fatty acid in the seed fat. As we have seen, cotton-seed oil is by way of being a by-product; the same may be said of soya bean oil, now produced to about the same extent as cotton-seed oil in the United States owing to the demand of the American farmer for soya bean cake. In the British Empire and elsewhere, except for coconut plantations, deliberate cultivation of oil-bearing species only commenced with that of the oil palm about 1910. Systematic cultivation of seed crops primarily for their oil content is thus still a comparatively young development in agriculture. Groundnuts will soon be grown in large quantities, and sunflower and some few other oil-seed crops are being developed; intensive cultivation of other selected species capable of yielding fatty oils suitable for edible, soap or paint purposes must be set in hand in tropical or sub-tropical localities with as little delay as possible—perhaps sesame, soya bean and some additional oils for edible fats and soaps, safflower, candlenut or other oils of a more unsaturated type to correct and relieve the over-dependence on linseed oil of the paint and allied industries. The information already vailable in the case of cotton seed will be of profound dvantage to those responsible for developing these ew fat resources.

Nevertheless, it is clear that for a long time to ome an important proportion of our vegetable fat pplies must continue to be derived, as of yore, om seeds or nuts grown by the native peoples in frica or elsewhere, or collected by them from the uits of wild trees and shrubs. Thus, the oil palm lantations still yield only about one quarter at most f the total supplies of palm kernels, while ground- uts have hitherto been cultivated only in primitive shion in India and in West Africa. Here it is of rgent importance to teach the native peoples and thers concerned two simple but essential principles : il-seeds must be gathered exactly at maturity ; they ust be thoroughly dried and kept dry until they ach the seed-crushing plants.

Dr. G. Scott Robertson, in his presidential address the Agricultural Section of the British Association st September, commented upon the enormous loss f good grain by insect and mould infestation. Loss nd deterioration of good edible fats in oil-seeds is ndoubtedly at present proportionately far greater, wing to the retrogressive changes, especially in the t, caused by damp conditions in storage and much ccelerated by enzymes already present in the seed, s well as those introduced by mould infection. Oil om native West African groundnuts may contain 0 per cent or more of free fatty acid, in which case ore than 30 per cent of the crude oil must be lost producing a refined edible oil. Indian groundnuts sually give oil with not less than 3 per cent of free tty acid. There is no reason why, if the principles eveloped in the cotton-seed industry and fully dis- ssed in the volume reviewed in this notice are pplied to groundnuts, the free acidity of crude roundnut oil should exceed 1 per cent, with cor- sponding improvement in its colour and general ppearance. The world production of edible fats ould be notably increased (by perhaps 10–15 per nt at least), without any increase in the tonnage f oil-seed crops, by insistence on these simple rinciples of hygiene in harvesting, storage and ansport.

T. P. Hilditch

CLASSIFICATION OF BACTERIA

ergey's Manual of Determinative Bacteriology
y Robert S. Breed, E. G. D. Murray and A. Parker itchens. Sixth edition. Pp. xvi+1529. (London : aillière, Tindall and Cox, 1948.) 82*s*. 6*d*.

TAXONOMY, "that branch of biology which treats of classification in accordance with a con- ntion or law", is the neglected foster child of cteriologists, most of whom call their pet *Bacillus* *is* or that-coccus, and for taxonomy care nothing at l. But however much classification may be neglected, y, even be despised, it is not only the bookworm d the historian who pursue it as an armchair udy ; it is also a field where research is active, and ere is increasing need that the newest ideas and chniques should be brought to bear on old problems bacterial relationships. The modern approach llects strains into groups with stable characters and nores minor differences that were once thought to important ; when the groups have proved their lue in classification they are given generic and specific names. Groups worked out according to this principle include the genus *Salmonella* and species like *Streptococcus pyogenes* and *Str. agalactiæ*, all of which have a serological basis. Much of the older work has now lost its value and should be reconsidered in the light of modern findings. The need for this is seen in the section on micrococci in "Bergey's Manual"; only twenty-two species are recognized (scarcely one is well characterized), but there is an appendix of more than four hundred names of so-called micrococci. As Abd-El-Malek and Gibson said recently, "The genus *Micrococcus* provides what is probably the worst example in bacteriology of uncritical systematic work".

Most systems of classification try to show natural relationships; but what criteria—morphology, metabolic activities, pathogenicity, or antigenic structure —are required to show these is unknown. Different relationships are brought out according to the criterion of kinship used; similarity of metabolic products makes cousins of streptococci and lactobacilli, morphology makes streptococci brothers of staphylococci, a relationship supported by the sharing of common antigens. "Bergey's Manual" adopts a classification based mainly on two characters, morphology and metabolic activities (where these do not clash), uses pathogenicity (as in *Erwinia*) to a small extent, and antigenic relationships scarcely at all. Few will quarrel with the outline classification into families, but fewer in Great Britain will accept the further subdivision into genera and species. In spite of an increase in the number of genera, there are welcome signs of retraction; *Eberthella, Proactinomyces* and *Staphylococcus* have disappeared, and *Klebsiella* has probably appeared for the last time.

By its title "Bergey's Manual" sets itself an impossible task : to construct, from data at present available, a key by which any bacterium can be identified. If we admit that, though perfection cannot be aimed at, such a key is desirable, there are two approaches to the problem : to limit the scheme to well-characterized species, using only proved criteria in the construction of the key ; or, the other choice, to include as many species as possible at the expense of having to use less stable criteria for species differentiation. In the "Manual" most writers adopt the second course ; notable exceptions are the sections on *Bacillus* and *Mycobacterium*, the authors of which have shown a welcome ability to cast historic but ill-defined species into oblivion, or to show their true status as synonyms.

If all sections resembled Nathan R. Smith's treatment of the genus *Bacillus*, with descriptions based on studies by modern methods of authentic cultures, there would have been no need to repeat vague details of ill-defined species, many of which are no longer available for study. It may not be ethically correct, but it would be a sound practical move to abolish priority and afford recognition only to species the types of which are preserved in dried or other permanent form, the naming and placing of such species being supported by adequate descriptions of the organisms and comparative studies with related species and genera. The editors of the "Manual" have made a move in this direction ; many species recognized in earlier editions and now mainly of historic interest are listed in appendixes.

Much effort would have been saved—and a better book produced—if writers of the different sections had recorded only species with which they were familiar from their own bench work.

S. T. Cowan

Electrolytic Polishing and Bright Plating of Metals

By Dr. S. Wernick. Pp. xv+243. (London: Alvin Redman, Ltd., 1948.) 30*s.* net.

IN the author's preface and in the foreword by Dr. U. R. Evans, great stress is laid on the commercial value of a brightly finished metal article, be it a piece of a machine or merely a luxury knick-knack. In the foreword it is further pointed out that there is a great practical utility in smoothness, and the examples of reflectors and bearings are quoted; but it is surprising that he does not mention the fact that electrolytic polishing seems to secure a measure of greater resistance to the normal tarnishing of metal surfaces. Except for a fairly full account of the anodic oxidation of aluminium, which is a rather exceptional case, the author's mention of corrosion is more or less limited to a couple of pages (146 and 147) in the chapter on carbon steel. Thus, when one considers the enormous sums of money that are annually expended in combating corrosion, it is surprising that (according to the author) for most metals the extent of the increased protection afforded by electrolytic polishing is rather uncertain.

It seems that to obtain a bright surface there are two rival processes, electrolytic polishing and the deposition of an inherently bright plate; and Dr. Wernick has written a very detailed account of the two techniques even to the extent of suggesting how the former may be used to reinforce the latter. The special attention devoted to nickel surfaces and the appendix on its bright plating are particularly interesting. Little or no theory is presented, as the exact mechanism of these processes does not appear to be understood; but this book is a wealth of empirical information. As such it will be of great value to the qualified chemical engineer and, being written simply and in a straightforward style, it can be recommended to manufacturers, works managers, etc., who may not have had any formal chemical training.

Dimple-Based Pottery from Central Kavirondo, Kenya Colony

By M. D. Leakey, the late W. E. Owen and L. S. B. Leakey. (Coryndon Memorial Museum Occasional Papers, No. 2.) Pp. 43. (Cambridge: Deighton, Bell and Co., 1948.) 5*s.* net.

STUDENTS of the later stages of African prehistory will welcome the publication of the detailed analytical study by Mrs. Mary Leakey of the iron-age pottery industry discovered by Archdeacon W. E. Owen in the Central Kavirondo of north-western Kenya. Isolated discoveries of pottery with little, if any, apparent affinity to known cultural groups are too frequently merely stored and their publication held over for further evidence. Since modern and recent domestic pottery in tropical Africa often appears to differ so slightly in the details of shape, ingredients and decoration, it is precisely the exceptional elements, like the occurrence of the impressed dimple in this Kavirondo material and its unusual decorative motifs, that are likely to be of significance to workers in other parts of Africa. The excellent drawings by Mrs. Leakey, supported by eight pages of photographs, and the descriptive analysis will give the reader a very accurate idea of the quality of this important pottery assemblage.

No definite age can be postulated for the dimple-based pottery until the geological significance of Owen's "Bed 5" horizon has been determined. The long-range correlation throughout the equatorial be of the pluvial phenomena deposited during the la important climatic phase (the Nakuran wet phase East Africa) presents difficult problems which ma well eventually be solved by the type of evidenc described in this paper. Recent discoveries in norther Nigeria of a pottery culture, associated with la neolithic and early iron-age material, in seale deposits of a widespread and persistent type invi a very tentative equation with similar deposi (Nakuran) in East Africa, and emphasize the impor ance of the early publication of *in situ* cultur material throughout the continent.

BERNARD FAGG

Gall Midges of Economic Importance

By Dr. H. F. Barnes. Vol. 3: Gall Midges of Frui (Agricultural and Horticultural Series.) Pp. 184 9 plates. (London: Crosby Lockwood and So Ltd., 1948.) 15*s.* net.

DR. BARNES is a tireless investigator with extensive output of original papers to h credit. He is, furthermore, a world authority on t Cecidomyidæ or gall midges and, therefore, the prop person to write a book of this kind. It forms t third of a projected series of volumes which he is write on gall midges of economic importance. planned, the series will run into eight volumes; t last volume is also to contain a general index to t whole series.

The present volume, like its two predecesso provides entomologists with well-documented a counts of all that is known about certain kinds gall midges—in this case those affecting fruit. Mu of Dr. Barnes' own work is incorporated in its page and he surveys the subject in a thoroughly compr hensive manner, since all known gall midges affecti fruit in different parts of the world are included. book of this kind, written in a terse but clear sty is invaluable to the horticulturist, the adviso officer and, in fact, to entomologists of all persuasio whether economic, biological or taxonomic in ou look. The long and complete literature list at t end of the book adds greatly to its value as authoritative work and will mark it out as a standa source for future reference. The author is to congratulated on his effort, and we wish him eve success in completing the task before him.

A. D. I.

Practical Zoological Illustrations

Invertebrates. By W. S. Bullough. 32 cards, 14½ × 9¾ in. (London: Macmillan and Co., Ltd., 194 15*s.* net.

THESE cards, illustrating the structure of vertebrates, are on the same lines as the vertebra series by Lockyer and Crofts. Selected types fr the protozoa, cœlenterates, flatworms, roundwor annelids, crustacea, insects and molluscs have be chosen, and a few figures of *Amphioxus* append The drawings are clear and bold, the directio concise, and the notes on the culture of some of t organisms should prove useful. But the set is m suited to the school than to the university, bei neither accurate enough nor full enough for first-y university students, who would discover errors many of the figures, for example, in the leg of t cockroach, the head of *Nereis* and the gills *Amphioxus*, and who would need sections as well dissections of their types.

The printing and production are excellent.

BLOOD CAPILLARY CIRCULATION UNDER NORMAL CONDITIONS AND IN TRAUMATIC SHOCK

By Prof. ROBERT CHAMBERS
Department of Biology, New York University, New York

AN important feature of the peripheral circulation is the close correspondence between the local needs of a given tissue and the amount of blood supplying it. Controlling mechanisms, to accomplish this, must involve more than the vasoconstrictor and dilator reactions of the terminal arterioles. Krogh attempted to ascribe the relative autonomy of the capillary circulation to the widespread occurrence of contractile, pericapillary elements, the Rouget cells. This has been considerably debated, and has never been adequately demonstrated. Moreover, there is till the question concerning the manner in which an adequate venous return can be maintained in spite of the supposed interposition, between arterioles and venules, of a network of extremely pervious capillaries[1]. The techniques hitherto used for observing he capillary vessels have been either too fragmentary or have lacked the required delicacy of experimental approach for ascertaining their highly reactive and inely balanced behaviour.

An adequate survey of the capillary bed for a study of variations in its functional activity requires a tissue in which the vessels can be traced from the arteriolar to their venular ends and, at the same time, can be exposed for observation with a minimum of trauma as not to upset the normal reactivity of the functioning components of the bed.

Three important regions, in which physiological fluctuations in blood supply occur normally from time to time, are the skin, the skeletal muscles and the viscera. In the skin, the circulation is somewhat specialized because of its temperature-regulating mechanism, and is a fertile, though difficult, field for investigation. The skeletal muscular system offers good possibilities. Unfortunately, in mammals it has the disadvantage that the trauma required for exposing it for microscopic study is excessive. Thus far, the most satisfactory has been the visceral region, particularly the mesoappendix of the rat and the omentum of the dog. The incision in the body-wall to expose these tissues is sufficiently far removed to obviate any direct effect of the trauma involved. Through the development of a technique for maintaining appropriate temperature, colloidal and moisture conditions, it has been possible to make prolonged microscopic observations over extended areas of the capillary bed of these visceral structures and to observe the effect of varied experimental procedures[2]. The studies have revealed that the capillary bed is composed of specialized vessels grouped into a series functional units. The integrated reactions of these units present a picture of the capillary bed as a differentiated organ possessing a highly specific function of controlling locally the supply of blood and the drainage of the tissue. This is accomplished by the peculiar structure and arrangement of the vascular components of the bed and by the highly sensitive reactivity of certain of the components to varying local conditions[3].

The concept developed concerning the visceral capillary circulation may be illustrated by analogy with the irrigation of a field under cultivation. Water is brought into the field by means of one or more main conduits carrying a continuous stream from one end of the field to the other. From these conduits the flow of the water can be regulated, by valves or sluice-gates, into side-canals which lead to all parts of the field. The return of the water is through other side-canals which empty into the lower ends of the main conduits and then to the outlet.

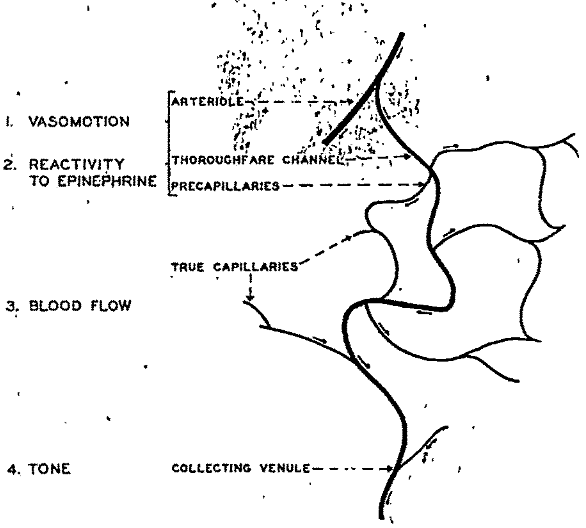

Diagram of a functional unit of a capillary bed

This simile, converted into terms of the capillary bed, is as follows. Well-differentiated, thoroughfare channels as conduits pass from the arterioles to their corresponding venules (see diagram). These channels possess outflowing branches along their proximal portions and inflowing branches along their distal portions. The branches connect with the network of capillaries lying on either side of the channels. The sluices of the capillary irrigation system are the intermittently functioning precapillary sphincters, located where the outflowing side-branches lead off from the upper or arterial segments of the thoroughfare channels. The alternating periods of closing and opening of the sphincters vary from about 20 sec. to 3 min. When the sphincters are relaxed, the precapillaries open up and permit the blood to flow from the channels into the network of the capillaries. When the sphincters are closed, the blood becomes restricted to the thoroughfare channels, which normally are always open and serve to transmit the blood pressure from the terminal arterioles to the collecting venules. Moreover, the continuous flow in the thoroughfare channels aids drainage from the capillary network through the inflowing branches which lead into the lower or venous segments of the channels.

The intermittent closing of the precapillary sphincters does not *per se* normally cause the capillaries of the network to collapse. Drainage, at the venous end, still continues, and, during this period, the capillaries, after being emptied of the corpuscular blood in them, exhibit a flow of a clear fluid which is filtering into them from the surrounding tissue spaces.

In summary, the capillary bed possesses three notable features: (1) a system of continuously flowing thoroughfare channels from arteriole to venule ; (2) intermittently closing sphincteric precapillaries, as abrupt side-branches emerging from the upper reaches of the thoroughfare channels and supplying the network of true capillaries with blood ; (3) relatively large postcapillaries entering at acute angles into the lower reaches of the thoroughfare channels. In accordance with the intermittent opening and closing of the precapillaries, the postcapillaries receive at one time blood and, at another, fluid filtering into the true capillaries from the tissue.

In resting ischæmic tissues, the closed periods of the precapillary sphincters are prolonged, during which time the blood courses only through the thoroughfare channels. The capillaries being devoid of blood, the intracapillary pressure falls and fluid filters into them from the surrounding tissue. Thereupon, the postcapillaries, which, similar to the true capillaries, are always open, now transmit a continuous flow of clear fluid into the venous end of the channel, and the tissue tends to be dehydrated.

On the other hand, when the tissue is activated, as in the case of muscle undergoing contraction, the open periods of the sphincters are prolonged. The result of this is a flooding with blood of all the true capillaries and an increase in intracapillary pressure with outward filtration which is accompanied by increased hydration of the tissue[4].

The sphincters are composed of smooth muscle cells, innervated by vasoconstrictor nerves. There is no good evidence for vasodilator innervation, but we do know that many tissue extracts and metabolites cause vasodilatation. On the basis of this we may draw the following conclusion. In resting tissue the metabolites are scanty and are not sufficiently concentrated to prevent the sphincters from responding to vasoconstrictor nerve impulses. Conversely, in activated tissue, the accumulated metabolites cause the sphincters to become refractory to nerve stimulation ; whereupon they relax and let blood through. These intermittent, constrictor and dilator phases of the sphincters and of the proximal muscular portion of the thoroughfare channel (metarteriole) constitute a precise mechanism delicately adjusted to the circulatory requirements of the tissues[5].

Having described the capillary circulation under normal conditions, let us consider the effects of acute hæmorrhage and of hæmorrhagic shock. In both, there is loss of fluid, for which the system tends to compensate by a widespread constriction of the larger blood vessels. What happens in the capillary bed ? Initially, the reaction is also compensatory. The sphincters contract, preventing egress of blood into the capillary network and restricting the blood to the thoroughfare channels. Meanwhile, the capillary network still continues to drain into the lower reaches of the channels. This serves as an additional compensatory reaction of drawing on the tissue fluid, thus increasing the volume of the circulating blood and causing hæmodilution.

In acute hæmorrhage[6], the compensatory reactions continue until the loss of blood reaches excessive proportions. There is then neither sufficient pressure nor volume of blood to supply the capillaries. The resulting collapse is mechanical in nature and usually not of sufficient duration to affect the vasoconstrictor reactions. There actually occurs an increase in the reactivity of the muscular vessels of the capillary bed which persists almost to the death of the animal. Adequate blood replacement is sufficient to bring about complete recovery.

In hæmorrhagic shock[7], the loss of blood extends over a much longer time. Throughout the somatic structures, in particular, the cutaneous and muscular regions of the body, there is a widespread and pronounced constriction of the blood vessels which continues during the entire shock syndrome.

In the visceral tissues there are initially the compensatory reactions characteristic of acute hæmorrhage. During the early period of the loss of blood, these reactions succeed temporarily in maintaining a good capillary flow. However, the flow gradually deteriorates. Proof has been presented of the existence of a vaso-excitor substance in the blood during the compensatory phase of the shock syndrome, and the predominating presence of a vaso-depressor substance during the later decompensatory phase[8]. This renders the precapillary sphincters refractory to constrictor impulses, whereupon they relax, a condition under normal conditions intended to spread the flow and carry away the accumulating metabolites. However, in traumatic[9] or hæmorrhagic shock the situation is vitiated by the inadequate propelling force and the poor inflow from the greatly constricted arteries. The little blood which now arrives slowly spreads throughout the bed and remains there, aggravating the general oligæmia and intensifying the deleterious effects of the accumulated metabolites.

When this state is reached, the reactivity of the muscular components of the capillary bed becomes depressed to such a degree that it cannot be recovered by the infusion of blood plasma. The impairment o the reactivity upsets the physiological integrity o the capillary circulation. Blood replacement at thi stage is not only ineffective but is actually harmful The infusion now merely dilates the minute vessel which no longer spontaneously possess the power o regaining their contractility. The infused blood then becomes pooled in the peripheral vascular system and the blood pressure which rose during the infusion falls again as soon as the infusion is stopped. Thi is the crucial phase in traumatic shock during which a more positive therapy than fluid infusion is required Preliminary experiments indicate that certain vaso tonic agents, which will not intensify the already constricted state of the larger vessels, are effective in extending the recoverability of dogs beyond the state in which the dogs are irreversible to bloo infusion[10].

In traumatic shock, involving fluid-loss, Nature' first provision is to drive blood away from the somato-muscular system so that the reduced circulating blood volume may effectively circulate where the blood flow is most needed, namely, the viscera organs. Hence the danger of bringing blood to the skin by warming the patient. When the bleeding patient can be promptly reached, fluid replacemen therapy is usually adequate. For the later stages o shock, it is significant that the infusion of blood o of blood plasma has been the preferred treatment.

The study of the capillary circulation in shock has emphasized the need of restoring the reactivity of it muscular components. It has also emphasized th need of a more thorough understanding of the peculia mechanism which enables the capillary bed t maintain a degree of autonomy from the rest of th blood circulation.

The account presented here is a brief summary o results obtained in association chiefly with D Benjamin W. Zweifach, now of Cornell Universit Medical College, under grants of the Committee o

Medical Research, Lilly Research Laboratories and the Josiah Macy, Jr., Foundation.

SCIENTIFIC INSTRUMENTS AT THE COPENHAGEN EXHIBITION

IT was appropriate that the conclusion of an Anglo-Danish trade agreement should have been followed by the exhibition of the products of British industry, which took place in Copenhagen during September 18–October 2. The Danes were thus able to assess for themselves the variety and quality of the manufactures which would be entering their country, in accordance with the terms of the trade agreement, while British exhibitors and visitors were enabled to sample far more freely than has been possible in Great Britain during recent years the Danish produce which was the subject of the converse part of the agreement. One abiding impression of the exhibition is the happy and almost festive atmosphere in which t was staged. Welcome was in the air at Copenhagen —being British was a passport to goodwill. We, on our side, contributed an exhibition of the products of our industry and added for good measure a visit by a contingent of our naval forces, the picturesqueness of the Gordon Highlanders, the spectacle of jet-planes in full flight, and the two-decked utility of British buses. The Danes responded with unlimited enthusiasm, courtesy and hospitality.

The exhibition was spread over a number of buildings in the city, and in one of them, the Gutenberghus, two floors were occupied by a display of cientific instruments. This exhibit took place under he ægis of the Scientific Instrument Manufacturers' Association of Great Britain and included the products of forty British scientific instrument firms. The first comment on this exhibit must not be in respect of the instruments themselves but of the unique and most attractive catalogue-brochure which was produced for the occasion. This brochure took the form f a series of biographies of the exhibiting firms, the ypes of instruments being produced by any one firm being indicated in the margin, and the illustraions covered one outstanding product of each firm. One gathers from reading this brochure that any British scientific instrument firm celebrating its jubilee is in the 'young person' class of the industry; firm which can point to a century of activity may lay claim to some measure of maturity. The really firmly established have their origins in the eighteenth r even the seventeenth centuries! The remarkable contribution to the advancement of knowledge made by men of science in Great Britain during the era of modern science has created a continuous demand for the manufacture of scientific instruments as aids to experimentation, and the fulfilment of this demand has meant that scientific instrument manufacture has been a lively activity in Great Britain certainly for three centuries. This fact is worth mentioning for two reasons. On one hand, it has been suggested, and in fact in some quarters assumed, that the traditional home of scientific instrument-making was elsewhere than in Britain. On the other hand, somewhat illogically, instrument manufacture in Great Britain has been criticized on the grounds that it is saturated with tradition and that it has been slow in keeping abreast of modern requirements. The evidence contained in the brochure refutes the one suggestion, and the actual exhibition of instruments at Copenhagen provided a visual demonstration that, whatever truth there may have been at one time in the criticisms of the design and utility of British scientific instruments, such criticisms are no longer valid.

Conversations with those responsible for science and technology in Denmark made it abundantly clear that in the past the term 'scientific instrument' has been synonymous, so far as they were concerned, with 'German scientific instrument'. Very justly they held German scientific instruments in the highest regard, and both their interest in and knowledge of instruments emanating from other countries were practically negligible. It was, therefore, most heartening to hear these same people express considerable astonishment at the range of British instruments exhibited at Copenhagen and to receive their unqualified admiration of the design and quality of the instruments. It would be foolish to decry the excellence of instruments made elsewhere than in Britain. An exhibition such as that held in Copenhagen does, however, make it evident that we shall be carrying our national diffidence of self-advertisement too far if we do not pay tribute to the equal excellence of our own.

The first impression gained by a general survey of the instruments which were shown was that we have travelled a long way since the scientific instrument was, in the main, a tool of the scientific laboratory. One of the exhibits which excited very great interest was a radar equipment, by means of which a display was presented on a cathode-ray tube of the contours —church spires, main streets, harbour installations —of the city of Copenhagen. The home of such an instrument is the bridge of a ship, and the conditions under which it would be of most use are the very antithesis of those to be found in a laboratory. The main use of many of the instruments of greatest precision is in the street or the open country on one hand, or as an attachment to a machine tool on the other. This ubiquity of use, while in no way diminishing the importance of the achievement of the highest accuracy of measurement, has required that the modern scientific instrument shall be characterized by simplicity of operation and robustness in use. A comparison of the instruments shown at an exhibition twenty-five years ago and those recently displayed at Copenhagen would clearly indicate both the revolution and design which has been necessitated by the large extension of the use of instruments, and the remarkable evolution of entirely new types of instruments which has occurred during the last generation. The new principle incorporated in phase-contrast microscopy makes possible the observation of a wealth of detail within the confines of what were formerly merely nebulous outlines. Incidentally, it has set the microscopist a pretty problem in interpretation. Electronic timing devices have made the pendulum appear a slow and cumbrous thing. The modern spectrograph, a most important industrial tool, has the lines of a gun turret rather than of a delicate scientific instrument. Any exhibition of modern scientific instruments provides both a survey of the growth of scientific knowledge and an indication of the extent to which science has intruded into every sphere of human activity.

The final word on the exhibition of scientific instruments at Copenhagen should be one of congratulation to British scientific instrument manufacturers, who in the short period of three years, after a long period of complete preoccupation with the production of instruments for military purposes, have most successfully reverted to their normal and natural activities. They have done this so completely, and in spite of the abnormal difficulties of the post-war years, that they are now able to meet the scientific, civil and industrial demands for instruments more abundantly than ever before in their history.

INTERNATIONAL UNION OF CRYSTALLOGRAPHY

THE first meeting of the International Union of Crystallography, which was held at Harvard University during July 28–August 3, provided an opportunity for the presentation of papers on many research projects that are being carried out in different parts of the world. More than seventy such papers were read, and there were many detailed discussions.

Some of the sessions—for example, those on "Alloy Phase Structures" and "Proteins and Related Structures"—were held at the same time, and it was therefore not possible for a single observer to attend all of them and so to present an account of the whole conference. Since, in addition, the collection of abstracts alone would occupy more space than could be allowed for this article, it has been decided to describe the work relating to a few topics only. This, unfortunately, means that many papers will not be mentioned at all; but it should be understood that the papers chosen for mention are not necessarily the most important, but are those that the present writer feels competent to knit into a coherent scheme.

It is inevitable that comparison should be made between the states of progress in the various countries represented at the Congress. In the thirty-six years since X-ray diffraction was discovered, many subdivisions of the subject have arisen, and it is interesting to see how these have differently attracted different nationalities. It is, of course, undesirable that some branches of the subject should be ignored in any one country, and, by and large, this has not happened in the countries of major scientific importance; only at such international conferences does any unevenness become apparent. Conversely, contacts made at these conferences should encourage people, perhaps subconsciously, to fill up any gaps that may exist.

These observations were well illustrated by the papers presented at the conference; but unfortunately the comparison can be made only between the United States and Great Britain; the latter had by far the largest foreign delegation and provided about one third of the papers read at the conference, while other countries—India, Canada, Sweden, Holland and Germany—provided only one tenth between them.

Instruments and Instrumentation

The session on instruments was almost entirely American, and this preponderance was evident also in the apparatus that was exhibited. It may be argued that this was naturally so since the conference was held in the United States, but to the writer it did not seem that American superiority was too strongly emphasized; there was some British apparatus on view, and the only important omission was that of demountable X-ray tubes—otherwise all the recent developments were American.

For example, probably the most important recent advance in X-ray analysis is the introduction of Geiger counters for measuring intensities; this may ultimately release X-ray workers from the tyranny of the photographic film. Geiger-counter spectrometers are being made both by Philips Laboratories and the General Electric X-ray Corporation in America, whereas in Great Britain the author is aware of their existence only in more primitive forms in certain laboratories. On the other hand, the American apparatus is directed toward the measurement of powder patterns, and, important as this measurement may be for industrial use, it has less theoretical importance than the study of single crystals. It is probable that this latter aspect is as far advanced in Great Britain as in America, but, in general, Geiger-counter apparatus is far more widely used in the United States.

As another example, Great Britain has produced nothing to compare with Buerger's precession goniometer. This instrument gives an undistorted reproduction of a section of the reciprocal lattice and is proving invaluable in the study of crystals with large unit cells. It is true that the indexing of photographs is not a limiting factor in the determination of crystal structures, but any aid to the shortening of this rather laborious operation must be welcomed and may even make practicable certain researches that are at present just outside the bound of possibility.

In methods of Fourier synthesis, practice in the two countries is at present more or less the same punched-card machines are greatly used by laboratories that have access to them, and printed strips with calculating machines, are used by the less fortunate. But this balance is likely to be altered when the electronic machine at the Alabama Polytechnic Institute is completed; this machine should enable a complete two-dimensional Fourier synthesis to be presented instantaneously as an image on fluorescent screen. With this instrument the major part of the operation will be the setting up of the coefficients; but, once these are set, changes in sig of certain coefficients can easily be introduced. It is possible that this instrument will make practicable the trial-and-error Fourier methods that have so often been suggested but never used.

Two other lines of progress must also be mentioned although they are not concerned with X-rays namely, electron microscopy and neutron diffraction. Dr. R. W. G. Wyckoff showed electron micrographs of crystals in which individual molecules appeared stacked together in orderly array. No intra-molecular detail appeared, of course, and it is likely that even the general appearance of the molecule is deceptive; but the fact that single molecules can now be observed is a striking testimony to recent progress with the instrument.

Dr. C. G. Shull gave an account of work on neutron diffraction. In this subject we pass from the orderly world of X-ray diffraction, where the intensity of scattering by an atom depends upon its atomic number, to one in which the intensity of scattering seems to be purely accidental; scattering factors have to be found by experiment and, as an extra complication, certain atoms scatter 180° out of phase with the others. Hydrogen is by far the best scatterer of neutrons, and thus neutron diffraction may settle certain arguments about the positions of hydrogen atoms in some organic crystals.

Crystal Structure Determination

As a contrast to American preponderance in the session on instrumentation, the session on crystal structure determination was largely British; W. L. Bragg and his Manchester school seem to have set a fashion that still persists. This fashion is to treat the problem as a puzzle in which the clues have to be searched for before the analysis can begin. Clues can be of quite different types, but ultimately the evidence they provide must all fit together to give the final answer—the crystal structure.

The work of Mrs. D. Hodgkin and C. W. Bunn on penicillin provides the best example so far of the co-ordination of a number of separate methods. At the conference Mrs. Hodgkin described similar work by J. D. Dunitz on the structure of calciferol (see also *Nature*, Oct. 16, p. 608). The compound used was $C_{35}H_{46}O_4NI$, and 123 parameters were involved. Since the general form of the molecule was known, the problem was not so difficult as the penicillin one, despite the larger number of parameters; nevertheless, the work must be regarded as an outstanding example of the use of heavy atoms in crystal structure determination.

This 'sporting' approach may be contrasted with the more severely logical American approach, which manifests itself in several different ways. For example, there is Buerger's systematization of the methods of interpretation of Patterson sections—the so-called 'implication' method; most workers in Great Britain have been content to derive the information in a rather casual way, which is adequate for simpler structures but may not give all the information that is contained in the sections.

A completely new approach to the general problem has recently been suggested in the form of the 'Harker–Kasper inequalities'. To most people in Britain the method seemed to be of limited utility, but it has been completely justified by its use in the determination of the structure of $B_{10}H_{14}$. Since the method is of greatest use for compounds in which all the atoms are approximately the same weight, it appears to fill a gap left by the development of the 'heavy-atom' methods.

The main recent British contribution to the 'logical' approach is A. D. Booth's use of 'steepest descents', which gives the variation in parameters necessary to improve the agreement between calculated and observed intensities. The method promises to be very useful for refining parameters in known structures, but it has yet to prove its worth in determining an unknown structure.

The 'fly's eye', described by de Vos, Clews and Cochran, provides a more typical example of the British approach. No new principle is involved—merely an appreciation of the relationship between the scattering of light and X-rays—but the apparatus enables the tedious process of calculating structure factors to be eliminated and so enables more structures to be tested than if the calculations had to be done separately for each.

To summarize, it will be seen that rapid progress is still being made in the field of crystal structure determination; still more complicated structures are being brought within the scope of existing methods, and completely new methods are being discovered and brought into use. Structures are being solved that would have been considered quite impossible of solution ten years ago.

Imperfect Structures

Important as the structures of perfect crystals may be, it must be realized that the most important materials, such as biological tissue, are highly imperfect and so their structures do not yield to standard methods of analysis. To these problems there are two methods of approach—the direct, typified by the Astbury school at Leeds, and the indirect, consisting of the study of slight imperfections first, and building on this foundation until the diffraction effects of the more complicated imperfections can be understood. Since the metals provide the simplest structures, it may ultimately appear that the biological problems are settled from an original study of metallic structures.

In this field progress seems to be about the same in both Great Britain and America. Dr. A. J. C. Wilson outlined the theory of diffraction by a one-dimensional imperfection, that for which the layers are perfect but are incorrectly stacked on each other. Examples of such imperfections were cited by Prof. W. Zachariasen, who dealt with the structure of uranyl fluoride, and by Dr. W. F. Bradley, who dealt with clays consisting of two different species of minerals. Imperfections in metals were dealt with by Dr. H. Lipson, who outlined some recent work on single crystals of $AuCu_3$; this crystal gives sharp main reflexions and diffuse superlattice reflexions. In addition, Dr. J. W. Fitzwilliam dealt with the effects of local order in some binary alloys such as $AuCu_3$, AuCu and AgAu.

As a contrast to these investigations, which are capable of theoretical treatment, Dr. H. M. Powell showed a remarkable set of Weissenberg photographs of the various layer lines from an organic crystal; the even layer lines showed sharp spots; but the odd layer lines showed continuous streaks along reciprocal-lattice lines. These effects can be accounted for qualitatively, but quantitatively their treatment is complicated by the complexity of the molecular structure; such photographs provide a striking challenge to the theoretician, and a complete solution of the problem should point the way to treatment of still more complicated imperfections.

The author would like to put on record his thanks to the Council of the Royal Society for enabling him to attend the conference, and to the organisers of the conference for enabling him to extend his stay in order to visit a number of laboratories where the work described in this article is being carried on.

H. LIPSON

OBITUARIES

Dr. C. M. Wenyon, F.R.S.

By the death of Dr. C. M. Wenyon, in London on October 24, at the age of seventy, the scientific world in general and tropical medicine in particular lost one of the foremost exponents of medical protozoology.

Charles Morley Wenyon, son of Dr. Chas. Wenyon, was born at Liverpool on March 24, 1878. He passed his childhood in China, where his father was a pioneer medical missionary, but returned to England for his education. He studied science at University College and medicine at Guy's Hospital, London, graduating B.Sc. (1901) and M.B., B.S. (1904). The dual training in zoology and medicine provided the right background to Wenyon's subsequent activities, and is a clue to the quality of his contributions to medical protozoology, a subject to which he devoted himself from the very beginning of his scientific career. During the first ten years (1904–14), he held with distinction the post of lecturer in protozoology at the London School of Tropical Medicine, where he worked under Patrick Manson. During this period he also continued his studies in Paris, under F. Mesnil, and in Munich, under Richard Hertwig (1906–7), and undertook an expedition for the study of protozoal diseases in the Sudan, where he spent a year (1907–8) working in a floating laboratory on the Nile. He was later (1910–13) sent by the School on missions to Mesopotamia, Syria and Malta, returning with abundant material which formed the subject-matter of important publications on oriental sore and kala-azar in these regions.

In 1914 Wenyon joined the staff of the Wellcome Bureau of Scientific Research as director of research in the tropics. Shortly after the outbreak of the First World War he was seconded—with the rank of lieutenant-colonel, R.A.M.C.—for work under the War Office and proceeded abroad. He carried out important researches on the intestinal protozoal infections, published in Wenyon and O'Connor's "Human Intestinal Protozoa in the Near East" (1917), and on malaria in Greece, the results of which appeared in a series of papers (*J. R.A.M.C.*, 1921–22). In 1924 Wenyon succeeded Sir Andrew Balfour as director-in-chief of the Wellcome Bureau of Scientific Research (now Wellcome Laboratories of Tropical Medicine) and director of research to the Wellcome Foundation, retiring in 1944, but continuing to act in a consulting capacity. Under Wenyon's direction the Bureau developed into a first-class scientific institute enjoying an international reputation among workers in tropical medicine and parasitology.

The variety and volume of Wenyon's contributions to protozoology render their assessment a difficult task. Though by no means restricted to purely medical questions, his work was chiefly concerned with protozoological problems having a direct bearing on tropical diseases. Much of our knowledge regarding the relative medical importance of the intestinal Protozoa and of the epidemiology of amœbiasis is due to Wenyon's pioneer work. He was particularly interested in the transmission of the leishmaniases. Though the credit of solving this problem belongs to others, his own researches and critical reviews of the existing data did much to clear the path for his successors in this field. The most outstanding work published by Wenyon, his *magnum opus*, is the well-known "Protozoology" (1926). This treatise, now generally recognized as a classic, gave a synthesis of our knowledge of the parasitic Protozoa and, though now in place out of date, it remains an indispensable referenc book for all serious students of protozoology.

Apart from research work, for many years Wenyo contributed authoritative reviews of the world literature on protozoal diseases to the *Tropical Disease Bulletin*. The present position of the Royal Society of Tropical Medicine and Hygiene in the medica world and the high quality of its *Transactions* ar due largely to Wenyon's untiring efforts during quarter of a century, first as its honorary secretar and ultimately as its president.

In 1927 Wenyon was elected a fellow of the Roya Society; he received many other honours and award both at home and abroad.

As a man, Wenyon was universally liked an respected for his friendliness and cheerful disposition His knowledge and experience were at everybody' disposal, and workers from all over the world, whe visiting London, never failed to call on him for advic and help. In his relations with immediate associate there prevailed a happy comradeship, in which 'C. M. W.' was *primus inter pares*. His colleagues wil remember with gratitude and affection his constan interest and encouragement in their work and welfare

C. A. Hoare

C. A. Hill

Charles Alexander Hill, founder of the Britis Drug Houses, Ltd., was born in London on Augus 18, 1874. He was educated at Winchester, King' College, London, and the Pharmaceutical Society' School of Pharmacy. His death occurred on Octobe 23.

C. A. Hill will be long remembered among men o science for the work he did in developing the manufacture of chemicals of high purity for use in researc and analysis which began in the 1914 crisis, when i became clear that Great Britain must no longe remain dependent upon importing supplies of thes chemicals from Germany or elsewhere.

Hill's natural abilities were well suited to this task he took a keen interest in science, passionatel insisted on accuracy in all matters, particularly i the written or spoken word, and was at all time disposed to devote meticulous attention to matte of detail.

Five years before the First World War broke ou the amalgamation of six companies concerned wit pharmaceutical manufacture had taken place unde Hill's leadership. Of the resultant company, th British Drug Houses, he had become chairman an managing director. At the outbreak of war, scientifi workers throughout Great Britain were made acutel conscious of their dependence upon imported laboratory chemicals, including organic chemicals for us in synthesis, and microscopical stains for use i bacteriology. This challenge made a profound appe to Hill and he applied his marked organising abilit to making good this defect. In the course of the ne ten years he achieved a great measure of success i so doing.

Important studies were made in determining t highest obtainable standards of purity for chemica in this category. New standards were in due cour formulated and submitted for acceptance to a independent committee set up for the purpose. Th analytical and research laboratories under h direction undertook much work in devising delica methods of analytical control; this led ultimately to numerous scientific publications by various members of his scientific staff.

It was a natural corollary to his achievement in setting up the manufacture of laboratory chemicals that Hill worked assiduously in the advocacy of the Safeguarding of Industries Bill, and later for having laboratory chemicals included in the list of goods scheduled under the Act.

Hill's family had long been connected with the Salters' Company; it was during his grandfather's mastership that the Salters' Company set an early example in founding research scholarships. Hill, who became master of the Salters' Company at an early age, was largely instrumental in the formation of the Salters' Institute of Industrial Chemistry, which has as one of its main objects the provision of funds for the training of men entering industrial chemistry.

Hill filled many public offices in connexion with pharmacy and pure and applied chemistry. His published addresses bear witness to his clear thinking and the high standards at which he always aimed. He became chairman of the Association of British Chemical Manufacturers and of the Wholesale Drug Trade Association, president of the British Pharmaceutical Conference, vice-president of the Institute of Chemistry and of the Society of Public Analysts.

The fine-chemical industry of Great Britain, which has undergone great growth during his life, has benefited by his notable contribution to its development.

FRANCIS H. CARR

We regret to announce the following deaths:

Dr. L. Doljanski, head of the Department of Experimental Pathology, The Hebrew University, Jerusalem, on April 13.

Mr. R. Murdin Drake, O.B.E., joint manager of the Association of British Chemical Manufacturers, on November 21, aged forty-five.

Sir John Fryer, K.B.E., F.R.S., secretary of the Agricultural Research Council, on November 22, aged sixty-two.

Mr. J. E. Kingsbury, a founder of Standard Telephones and Cables, Ltd., and an active member of the Society of Telegraph Engineers and later of the Institution of Electrical Engineers, on November 4, aged ninety-three.

NEWS and VIEWS

Nobel Prize for Physics:
Prof. P. M. S. Blackett, F.R.S.

THE Nobel Prize for Physics, for the year 1948, has been awarded to Prof. P. M. S. Blackett, of the University of Manchester. The most important of Blackett's contributions to experimental physics have been made with the Wilson expansion chamber. After the discovery of the artificial transmutation of some of the light elements by Rutherford in 1919, it became important to make a detailed study of individual disintegrations, and this could only be done with the Wilson chamber. In order to observe the transmutation of a nitrogen nucleus, it was necessary, however, to consider making many thousands of photographs. For this purpose, Blackett developed the automatic expansion chamber. The successful design and operation of this elaborate instrument, in which the many operations involved in taking a single photograpb were made mechanically, in an ordered sequence many times repeated, represented a technical achievement of the highest order. With this instrument, Blackett secured the classical photographs, now familiar to many generations of physics students, showing the disintegration of nitrogen by fast α-particles; and many other examples of nuclear processes.

The experience in design and operation gained with the automatic expansion chamber formed the basis for the next technical advance, the development of the counter-controlled Wilson chamber. If an ordinary chamber is expanded at random, the chance of observing the tracks of particles of the cosmic radiation is very small—in the case of apparatus of conventional design operated at sea-level. In collaboration with G. P. S. Occhialini, Blackett therefore arranged that the expansion should take place only when one or more particles had passed through the chamber. This was secured by a 'trigger' device which operated only if a particle passed through both of two Geiger counters, placed one above and one below the chamber. In this way the beautiful photographs of showers of positive and negative electrons—the 'soft' component of the cosmic rays—were obtained. The principle thus introduced, of combining the particular features of the Wilson chamber with those of the Geiger counter in a single apparatus, continues to be one of the most fruitful methods in the physics of the cosmic radiation. Blackett was also a pioneer in the development of apparatus for studying the deflexion of cosmic ray particles in Wilson chambers operated in strong magnetic fields—a method of great importance for the development of our knowledge of the momenta of cosmic ray particles. This present recognition of his distinctive and original contributions to physics will be welcomed everywhere.

Centenary of H. A. Rowland

NOVEMBER 27 marks the centenary of the birth of Henry Augustus Rowland, one of the most distinguished men of science that the United States has produced. Born at Honesdale, Pennsylvania, on November 27, 1848, Rowland was the son of a clergyman, and at the age of sixteen, after being allowed to abandon his classical studies, he devoted himself to science. He studied to be a civil engineer at the Rensselaer Polytechnic Institute at Troy and graduated in 1870. During the next few years he successively served as a railway engineer, taught in the Wooster College and lectured as assistant professor at the Rensselaer Institute. On April 3, 1876, he became the first professor of physics at the newly created Johns Hopkins University at Baltimore, having the previous year visited Europe and worked for a time under the great Helmholtz. Rowland retained the professorship until his death, adding lustre to the University by his own brilliant researches and by the band of devoted workers he gathered around him.

Rowland's greatest researches were those on the determination of the mechanical equivalent of heat, the determination of the ohm and the study of the solar spectrum. In 1882 he described to the Physical Society his celebrated diffraction grating which placed in the hands of the spectroscopist a new and powerful instrument of research—one which made it possible to photograph spectra directly without the use of prisms or lenses and with a greatly increased dispersion and resolving power. In 1888 he published a photographic map of the normal solar spectrum, in 1893 a table of standard wave-lengths, and in 1895–97 a table of solar wave-lengths. For his discoveries and investigations Rowland received the Rumford, the Draper and the Matteucci Medals and was honoured in many ways by societies and universities. Besides being a great investigator, he was a great teacher, kindling in his students an enthusiasm approaching his own. His work was always distinguished for refinement and accuracy; and withal he possessed the true scientific temperament. "For myself," he said once, "I value in a scientific mind most of all that love of truth, that care in its pursuit and that humility of mind which makes the possibility of error always present, more than any other quality. This is the mind which has built up modern science to its present perfection, which has laid one stone upon the other with such care that it to-day offers to the world the most complete monument of human reason." Rowland died at his house in Baltimore on April 16, 1901. His body was cremated and his ashes buried beneath his famous ruling engine. His library was in 1903 given by his widow to the Johns Hopkins University.

Mathematics at Ibadan

THE chair of mathematics at University College, Ibadan, Nigeria, has now been filled by the election of Dr. F. V. Atkinson. Educated at St. Paul's School and at the Queen's College, Oxford (of which he was an open scholar during 1934–37), Dr. Atkinson was later a Senior Demy of Magdalen. During the War he served with the Army in India, reaching the rank of major, and he returned to Oxford in 1946 as lecturer in mathematics at Christchurch. Dr. Atkinson's work has been chiefly concerned with the analytical theory of numbers, and the properties of the Riemann ζ-function.

Reading Institute of Education

AN Institute of Education has been established in Reading as the area training organisation for Berkshire, Buckinghamshire, Hampshire, Oxfordshire, West Sussex and Reading. The scheme for the Institute provides for a Board of Governors drawn in equal proportions from the local education authorities in the area and from the University of Reading. The Minister of Education has appointed Sir Frank Stenton, vice-chancellor of the University, as chairman. The principal objects of the Institute are to further the training of teachers and other persons intending to engage in educational work in the area; to foster close relations between the corporate members of the Institute (at present, the University of Reading, the county councils and county borough councils in the area and the training colleges in the area, namely, Culham, Bishop Otter, Easthampstead Park and Newlands Park); and to establish an educational centre for the promotion of the educational interests of students and teachers and other persons professionally concerned with or interested in education in the Institute area. The Institute will be established in or near Reading, and a search for suitable accommodation has already begun; ultimately it is hoped that the Institute will have a new building designed for the purpose. Mr. C. R. E. Gillett has been appointed director of the Institute.

Sources of Technical Assistance

A SURVEY of the technical assistance available for economic development in the United Nations and the Specialized Agencies has been prepared by the secretariat for the second session of the Sub-Commission on Economic Development of the Economic and Employment Commission (London: H.M. Stationery Office. United Nations, E/CN.1/Sub. 3/22. June 2, 1948). Its immediate purpose is to facilitate examination of provisions currently being made for such assistance to members of the United Nations in their programmes of economic development, and particularly to assist the Sub-Commission in considering measures for increasing the availability and effectiveness of such technical assistance. Its scope is limited to those activities, excluding the provision of funds and relief supplies, which are designed to assist economic development; provisions for technical assistance in the sphere of social welfare are not described in detail. The Survey gives a very clear but concise account of the types of assistance available, including that in the form of research and information, as well as international training, panels and conferences; and also of the sources of assistance. It then reviews in succession the various fields such as agriculture, forestry and forest products, fisheries, education and technical training, labour and employment, health, nutrition and safety, finance and currency, or statistics in which such assistance might be required. The Survey contains nothing that is new; but gives a convenient and impressive picture of the elaborate and interlocking organisation for world co-operation which has already been built up, and which could be used if the will to do so were genuine and widespread.

German Hydrographic Journal

REFERENCE was made in *Nature* of September 4, p. 364, to the first issue of the *Deutsche Hydrographische Zeitschrift*. The next two numbers have now appeared: Vol. 1, No. 2/3, June 1948; and Vol. 1, No. 4, August 1948. The former contains articles on problems of marine geology, coastal geodesy, terrestrial magnetism and oceanography, whereas No. 4 is completely devoted to oceanographical and tidal problems. An essay by O. Pratje on the bottom sediments of the southern and middle Baltic and their importance for the interpretation of fossil sediments is based on about a thousand bottom samples which had been collected in the years just before the War. It is accompanied by detailed charts and profiles. F. Rudolf Jung examines the limits of applicability of transit-bearing and of the trigonometrical determination of distances in the technique of marine surveying, and gives numerical and geographical aids for the practical work in question. F. Errulat deals with the mean intensity of great geomagnetic disturbances as dependent on geomagnetic latitude, and finds interesting relations with the results of J. Bartels. G. Neumann writes on resonance-oscillations of bights and on the mouth correction for seiches; his treatment of the Frische Haff agrees well with results which H. Lettau had derived from the registrations of tide gauges. F. Model discusses the thickness of the ice on the Alster in Hamburg towards the end of the severe winter of 1946–47. On the open basin a thickness of 51–56 cm. was found; below a rather broad and low bridge it fell to only 12 cm. G. Wust, studying once again the temperature-inversion in the deep waters of the South Atlantic, finds a remarkably close association between the inversion and the bottom relief, and points out that the depth of the inversion rises and sinks in accordance with the semi-diurnal tide. There are probably also seasonal and aperiodic pulsations. An important paper by W. Horn gives a concise and partly new representation of the tides as a function of time. G. Tomczak describes a wave gauge, an instrument for measuring short-period oscillations of pressure in the sea, and F. Nusser presents a notable report on ice-conditions on and off the German coasts during the severe winter of 1946–47.

Chemical Prevention of Potato Dry Rot Disease

As a result of research during the past five years, Bayer Products, Ltd., Crawley Research Station, Brighton Road, Crawley, Sussex, claim to have developed a highly efficient preparation for the prevention of dry rot of potato tubers caused by the fungus *Fusarium cœruleum*. This preparation, marketed under the trade name of 'Fusarex', is based on 2,3,5,6 tetrachlornitrobenzene, a chemical first described in 1868 by Jungfleish, who prepared it by treating tetrachlorbenzene with fuming nitric acid for some hours at near boiling point. 'Fusarex' is most effective for the control of dry rot when applied to the tubers immediately on lifting, followed by a period of four to six weeks storage in a clamp. It has been found in trials that the preparation does not need to cover each potato completely so long as an even distribution through the mass of tubers is obtained. Thus a simple manual application can be employed, involving no expense in labour or machinery, and no interference with the normal lifting operations. It has also been found that suitable 'Fusarex' treatment and storage conditions can delay the development of sprouts by the tubers. The treatment of main-crop varieties to prevent sprouting is now a practical proposition; but special techniques are still being worked out for early varieties. Intensive pharmacological tests have shown that tetrachlornitrobenzene is of such a low order of toxicity that it can be regarded as non-poisonous under the conditions of use suggested, and it is therefore safe to use on potatoes destined for human consumption and stock feeding.

Jewels for Instruments

A REVISED edition of "British Standard 904", first issued in 1940, has recently been published (British Standard 904 : 1948. Dimensions of Instrument Jewels. Pp. 12. (London : British Standards Institution, 1948.) 2*s*. net). The forms and dimensions of V-jewels, ring stones and end stones for instrument purposes, and compass jewels, are specified; and in an appendix the method and apparatus required for the inspection of jewels is described. The Standard does not relate to jewels for watches and clocks, for which a separate British Standard is being prepared, nor to cup jewels for integrating meters, the form of which is still the subject of research.

Sun-Bathing by Birds

RECENT communications to *British Birds* have directed attention to the widespread occurrence of the habit of sun-bathing among birds. The question has been raised "whether irradiation of the skin, with its consequent effect of vitamin D production, could take place through sun-bathing". Prof. W. C. Wynne-Edwards has stated that direct irradiation of the skin is usually impossible in both birds and mammals because of their thick coats. From observations lasting over sixteen years, however, Noble Rollin has collected photographs and information which lead him to the belief that irradiation of the skin takes place among jackdaws, chaffinches, blackbirds, hedge-sparrows and house-martins, although no evidence of sun-bathing has been observed among gulls and wading birds (*British Birds*, **41**, No. 10; October 1948).

Science Progress

AMONG the articles in the current issue of *Science Progress* (**36**, No. 144; October 1948) is one which has not only the appeal of a biography of a well-known man of science but also the charm of writing which reminds one of Maurois. This is "Augustin Fresnel: His Time, Life and Work, 1788–1827", by G. A. Boutry, director of the Laboratoire d'Essais, Paris. In the same volume Prof. H. P. Himsworth contributes a masterly survey of recent developments in the researches into liver disease, while E. E. Schneider's review of contemporary knowledge of the electronic structure of solids and H. H. Macey's consideration of the theoretical aspects of clay consolidation are supported by an article on the relationship between "Indeterminism and the Wish" by J. C. Gregory. The volume also contains the usual summary of recent advances in various aspects of science and a considerable number of reviews.

Proceedings of the Physical Society

IN order to accommodate the increased number of papers submitted for publication, the *Proceedings of the Physical Society* is to appear in two parts, *A* and *B*. *Proceedings A* will include a contents list of the corresponding *Proceedings B* and vice versa. Section *A* will include subjects such as quantum theory, statistical mechanics, nuclear physics and cosmic rays, atomic physics, molecules, spectra, theories of solids, liquids and gases, surface phenomena, growth and properties of crystals, crystal structure, luminescence, electrodynamics, heat and thermodynamics, standards. Section *B* will include subjects such as acoustics, including ultrasonics, optical design, electron optics, colour, elasticity and other mechanical properties of solids and liquids, crystal structure analysis, magnetic materials, refrigeration and liquefaction, electric discharges, radio, geophysics, including ionosphere, astrophysics, solar physics.

International Congress of Mathematicians

AN International Congress of Mathematicians will be held in Cambridge, Massachusetts, during August 30–September 6, 1950, under the auspices of the American Mathematical Society. It will be open to mathematicians of all national and geographical groups. Harvard University will be the principal host institution. A number of other institutions in Boston will join in the entertainment of Congress visitors. In recent years, mathematicians have been much impressed by the success of the conference method for presenting recent research in fields in which vigorous advances have just been made or are in progress. The 1950 Congress will include conferences in several fields. Following established custom, there will also be a number of invited addresses by outstanding mathematicians. In addition, sectional meetings for the presentation of contributed papers not included in conference programmes will be held in the following fields: I, Algebra and Theory of Numbers; II, Analysis; III, Geometry and Topology; IV, Probability and

Statistics, Actuarial Science, Economics; V, Mathematical Physics and Applied Mathematics; VI, Logic and Philosophy; VII, History and Education. The official languages of the Congress will be English, French, German, Italian and Russian. Harvard University has offered the use of its dormitories and dining-rooms for mathematicians and their guests for the period of the Congress, and the Organising Committee hopes that it will be possible to furnish board and room without charge to all mathematicians from outside the North American continent who are members of the Congress. Congress membership fees will be announced well in advance of the opening of the Congress. Every effort will be made to facilitate the travel at reasonable cost of foreign participants while in the United States. Communications about the Congress should be addressed to the American Mathematical Society, 531 West 116th Street, New York City 27, U.S.A.

Congress of Comparative Pathology

The International Congress of Comparative Pathology will hold its fifth meeting in Istanbul during May 17–20, 1949. The Congress covers all aspects of human, plant and veterinary pathology, and considerable latitude is permitted in the choice of subjects for discussion. The British National Committee (chairman, Prof. T. Dalling, Ministry of Agriculture) will be glad to receive, as soon as possible, the titles of communications which members in Great Britain, who hope to attend the Congress, wish to submit for transmission to the Secretaire Générale of the Permanent Committee. Further information can be obtained from Mr. R. E. Glover (honorary secretary, British National Committee), Royal Veterinary College, London, N.W.1, or from Pr. N. R. Belger, Taksim, Siraserviler 75/3, Istanbul.

Commonwealth Fund Fellowships

The Commonwealth Fund of New York is offering in 1949 a number of fellowships for British subjects to study in the United States for one year. Twenty such fellowships will be available to British subjects between twenty-three and thirty-five years of age, who are graduates of a university of the United Kingdom or who have studied in one, having previously graduated from a university of Australia, New Zealand or South Africa. In addition there are three fellowships for candidates holding permanent positions in the higher ranks of the Civil Service of Great Britain, and five more fellowships for those in Government service in the Commonwealth. The emolument consists of a total grant of approximately 950 dollars with an allowance of 200 dollars a month plus free travel to and from the United States. Applications must be submitted by February 1, 1949, and full details may be obtained from the Secretary of the Committee of Award, 35 Portman Square, London, W.1.

Royal Meteorological Society: Popular Lectures

The Royal Meteorological Society has arranged a series of monthly meetings, to be held at the Science Museum Lecture Theatre, Exhibition Road, South Kensington, and visitors will be welcome. The first meeting, on December 3 at 5.30 p.m., will consist of a film show, and thereafter popular lectures will be delivered at 6 p.m. by the following speakers on the dates shown: Sir George Simpson, January 12; Sir Nelson Johnson, February 10; Prof. Gordon Manley, March 3; Dr. G. M. B. Dobson, April 6; Mr. E. Gold, May 5.

University of London: Appointments

The following appointments in the University of London have been announced. Dr. Dennis Gabor has been appointed to the Mullard readership in electronics tenable at the Imperial College of Science and Technology, London, as from January 1, 1949. The title of reader in the University has been conferred on the following: Dr. Vera Fretter, lecturer in zoology at Birkbeck College; Dr. P. A. I. Gorer, of the Department of Experimental Pathology, Guy's Hospital Medical School; Dr. G. E. Newell, lecturer in zoology at Queen Mary College.

The degree of D.Sc. has been conferred on Mr. E. J. Popham, an external student.

The Night Sky in December

Full moon occurs on Dec. 16d. 09h. 11m. U.T., and new moon on Dec. 30d. 09h. 44m. The following conjunctions with the moon take place: Dec. 2d. 16h., Jupiter 4° N.; Dec. 2d. 17h., Mars 3° N.; Dec. 21d. 09h., Saturn 3° S.; Dec. 28d. 06h., Venus 4° N.; Dec. 31d. 19h., Mars 4° N. In addition to these conjunctions with the moon, Mars is in conjunction with Jupiter on Dec. 1d. 08h., Mars 1·1° S. Mercury rises at 7h. 15m. on Dec. 1, or nearly half an hour before sunrise, but is too close to the sun for observation, and is not favourably placed for observation during the month. Venus is a morning star, rising at 4h. 40m., 5h. 23m. and 6h. 09m. at the beginning, middle and end of the month, respectively. The magnitude of the planet is − 3·4 during December, and the visible portion of the illuminated disk varies from 0·84 to 0·90. Mars is still too close to the sun for favourable observation, setting less than an hour and a half after the sun throughout the month. Jupiter is also too close to the sun to be well observed, and is in conjunction with the sun on Jan. 1. Saturn, in the constellation of Leo, rises about 23h. on Dec. 1 and 21h. on Dec. 31; it is visible throughout the morning hours in the early part of the month and also during the later hours of the night in the last part of the month. The planet is stationary on Dec. 17. No occultations of stars brighter than magnitude 6 take place during December. Winter solstice occurs on Dec. 21d. 23h.

Announcements

Dr. W. Campbell Smith, keeper of the Department of Mineralogy in the British Museum (Natural History), has been appointed to the new post of deputy chief scientific officer in the Museum; he will retain his post in the Department of Mineralogy. Dr. Maurice Burton has been appointed a senior principal scientific officer (deputy keeper) in the Department of Zoology.

The following appointments have been made in the University of Leeds: Mr. W. J. Thomas, as lecturer in agricultural economics; Dr. A. D. Walsh, as lecturer in inorganic and physical chemistry.

The following have been appointed officers of the Society for Visiting Scientists, 5 Burlington Street, London, W.1: *President and Chairman*, Sir Harold Spencer Jones; *Secretary*, Prof. F. J. M. Stratton; *Treasurer*, Mr. H. R. Walters.

Œstrogens in Grass and their Possible Effects on Milk Secretion

STUDIES of variations in the composition of cows' milk[1,2] have revealed a progressive decline in the non-fatty solids content during the winter months, followed by a substantial and immediate rise when the cows are turned out to grass in the spring. Also it is widely recognized that on 'going out to grass' cows often show an increase in milk yield, greater than the amount ascribable to the extra nutrients ingested.

Attempts to simulate these (galactopoietic) effects of spring grass on milk yield and composition by liberal supplements of carbohydrate, protein or carotene to the ordinary winter rations of cows gave no response, though the characteristic effects were shown when these cows were later given access to spring pasture[2]. It therefore seems reasonable to conclude that these effects are due to the presence in young, rapidly growing grass of a galactopoietic factor such as a hormone or vitamin.

In speculating upon the nature of this postulated galactopoietic factor, we were impressed by the findings of Bennetts and his collaborators[3,4], who observed, in sheep grazing on subterranean clover in Western Australia, histological changes in the reproductive organs of both sexes which pointed to the presence of an œstrogen in the pasture, a conclusion which was later strengthened by the extraction of œstrogen by chemical methods[5]. These findings, taken in conjunction with those of Folley and his co-workers[6,7], who showed that administration of œstrogens will increase the solids content of cows' milk (enrichment effect), indicated the possibility that part at least of the galactopoietic effects of spring grass at the time of maximum growth might be due to the presence of œstrogens. Such a theory would also account for milk yield increases, since the 'enrichment effect' is only one aspect of a general galactopoietic action exerted by œstrogens under suitable conditions[8]. We were thus led to examine the growing herbage of English dairy pastures for the presence of œstrogen.

Samples of herbage cut from a number of pastures during the period of active growth were extracted by a method developed by Mr. T. J. Robinson, details of which were kindly made available by him in advance of publication. The method involves extraction with ethanol, followed by saponification and separation of the phenolic fraction. The extracts were tested for œstrogenic activity by the effect on the weight of the uteri of immature mice, six mice being used in each group. The extracts were dissolved for njection in arachis oil, and the dose given in six subcutaneous injections over three days, with autopsy eighteen hours after the last injection.

The results are noted in the accompanying table; he first series (Nos. 1–7) refers to tests of grasses cut at the early flowering stage in May 1948 at a ime when, though plant growth was restricted by adverse weather conditions, cows grazing the pastures showed moderate increases in milk yield and non-fatty solids. The second series (Nos. 8–14) refers to herbage from a number of pastures at the second seasonal cutting on June 23, 1948, and to a hay which was a year old and was included for comparison. This herbage was in the pre-flowering stage. Extracts of the two grass samples in the first series (Nos. 2, 3, 4 and 5) gave significant uterine weight increases over the controls ($P < 0{\cdot}05$), and the herbage undoubtedly contained œstrogen. The second series demonstrated œstrogen with certainty in the clover (No. 12) and probably in the grasses (Nos. 10 and 11), while the hay (No. 13) was negative.

Serial No.	Treatment	Mean uterine weight (mgm.)
	First series	
1	None	7·8±0·8
2	Grass No. 1: Extract equiv. to 0·75 gm. dry matter	14·2±1·1
3	,, ,, ,, 1·50 ,, ,, ,,	24·5±2·4
4	Grass No. 2: Extract equiv. to 0·75 gm. dry matter	19·6±1·7
5	,, ,, ,, 1·50 ,, ,, ,,	20·0±1·2
6	0·03 μgm. α-œstradiol	23·0±1·8
7	0·06 μgm. α-œstradiol	29·3±3·0
	Second series	
8	None	5·3±0·4
9	Arachis oil	6·4±0·5
10	Grass No. 3: Extract equiv. to 0·75 gm. dry matter	8·8±0·9
11	Grass No. 4: Extract equiv. to 0·75 gm. dry matter	9·9±0·8
12	Clover ,, ,, ,, 0·75 ,, ,, ,,	15·1±1·0
13	Hay ,, ,, ,, 0·75 ,, ,, ,,	6·3±0·8
14	0·03 μgm. α-œstradiol	17·4±1·5

These preliminary results are in harmony with the theory that the galactopoietic effects of spring grass in lactating cows may be due to the presence of œstrogen, and justify further work, which is planned, to examine various aspects of the theory in greater detail.
